An important point is that for multiple printing, the individual negatives should have approximately the same gradation, and a plate was tested in a Scheiner sensitometer with an amylacetate lamp, with a cell filled with water, with methyl violet solution 1:10000, and acid violet solution 1:2000, and the result is shown in Fig. 4, from which it will be seen that the

Fig. 4.—Characteristic curves on gelatino-bromide plate:—1. Behind a water filter. 2. Behind methyl violet filter. 3. Behind acid violet filter.

characteristic curves are practically parallel, but that the light is much reduced.*

The green sensitive plates which are used for the red printing plate are not easy to prepare; the sensitiveness should extend

* Scheiner's sensitometer is practically the same as the Harter and Driffeld, but with different ratio of apertures in the rotating disk. This experiment, whilst instructive and interesting, does not answer the argument brought forward so frequently in England by the advocates of the single plate system, that it is impossible to secure similar gradation on plates of differing colour sensitiveness, nor am I aware of any actual test of this point.—E. J. W.

from D through the blue-green to beyond F. The erythrosine plate, which is generally used, and is still the best,* has too little sensitiveness to blue-green, and is too sensitive to yellow, and therefore in order that the latter should not act too strongly it must be dampened by blue or green filters, and a generous exposure must be given to allow the blue-green to act sufficiently.

Most commercial orthochromatic plates are erythrosine plates. For his experiments the author used bathed plates, softening them first by bathing in water 100cc., ammonia 1.5cc., for two minutes, and sensitising by soaking for a similar time in water 100cc., erythrosine solution 1:500 6cc., ammonia 1.5cc., and drying in absolute darkness.

Eosine, or allied dyes, which give greater sensitiveness towards the green, should be theoretically more correct than erythrosine, but unfortunately the general sensitiveness and that to blue-green is so much less that in spite of a strong damping filter the exposure for the erythrosine plate is less. Collodio-bromide emulsion, sensitised with eosides of silver, made from sodium tetrabromofluoresceine, or ethyleosine, phloxine, etc., acts better than gelatino-bromide of silver and eosine. Fluoresceine silver is very sensitive to green, but too little sensitive to yellowish green, and therefore not sufficiently so for trichromatic work. With this and all plates similarly sensitised green pigments have sufficient photographic density, but yellows have not.

Monobromofluoresceine silver in collodio-bromide emulsion acts very well, for its sensitiveness to dark green is similar to that of fluoresceine, but it acts less vigorously than eosine in the yellow-green, which is what is required. The author finds the best formula for a green sensitive emulsion to be 100cc. of collodion emulsion, such as Albert's, mixed with 10cc. of alcoholic solution of monobromofluoresceine 1:500,† with, in some cases, a small addition of cyanosine or ethyleosine.

With all these green sensitive plates there is always a vigorous blue-violet sensitiveness, the particular sensitiveness of silver bromide, which must be dampened by a suitable yellow filter, and this is an important point.

The blue printing plate is made on a red sensitive plate behind an orange filter, and such plates should be sensitive at least from C to beyond D, to the limit of the yellowish green. According to the author, sensitisers with a maximum between C and D, which with generous exposure reproduce beyond C, are satisfactory, and Wollschwarz (wool-black) and nigrosine are satisfactory, for the action extends beyond A. Commercial collodion emulsion is sometimes unsatisfactory.

The author sensitises his red printing plate with Wollschwarz as follows, with excellent results:—An ordinary gelatino-bromide plate is first soaked for two minutes in a 1.5 per cent. solution of ammonia, then for the same time in a sensitiser of

Wollschwarz 4B (B. A. A. Fabrik) 1:500	5cc.
or Dianilschwarz N (Meister, L. and B.) 1:500	5cc.
Water	100cc.
Ammonia	1.5cc.

The plate is bathed in this for two minutes, and then in a bath of similar constitution for another two minutes, and dried in complete darkness.

For typographic work the following collodion emulsion is particularly suitable:—

Albert's collodion emulsion	100cc.
Ethyl violet solution (1:500)	5cc.
Monobromofluoresceine solution (1:500)	5cc.

After coating, the plates are bathed in a 1:500 silver bath (not acidulated), and exposed wet.

* It must not be overlooked that later researches by Valenta, König, and Hübl have given us some very energetic green sensitisers which completely oust the erythrosine plate.—E. J. W.

† This dye is made by the Badische Anilin u. Soda Fabrik, Ludwigshafen, but it cannot be obtained commercially, though Messrs. Penrose inform me that they hope to obtain some.—E. J. W.

The monobromofluoresceine is added to the ethyl violet plate because it gives better general sensitiveness and cleaner plate. Frequently emulsion thus freshly prepared gives fog, but after keeping a week or two works quite clean; but if after exposure the plate be bathed in dilute acetic acid there is no fog.*

WHAT WOMEN HAVE DONE FOR ASTRONOMY IN THE UNITED STATES.

[Abstracted from *Popular Astronomy* for March.]

THE United States of America is a large country with large hearted and liberal-minded people. There is no other country in the world where women, as a class, have advanced so rapidly. In their studies they encounter very little narrow-mindedness and jealousy among their fellow-workers in the same field. research, but, in general, are treated with the greatest courtesy, encouragement, and assistance. While we cannot maintain that in everything woman is man's equal, yet in many fields she works her patience, perseverance, and method make her his superior. In no line of work has her influence been felt more than in the field of astronomy. A review of the progress of astronomical research during the past century is incomplete without a distinct recognition of woman's activity in furthering the science, not only by actual work, but also by substantial pecuniary assistance.

Williamina Paton Fleming was born in Dundee, Scotland, May 15, 1857. She was the daughter of Robert Stevens, picture dealer. She received her early education in her native town in the public schools, in which she subsequently taught for five years. In 1877 she married James Orr Fleming, of Dundee, Scotland.

On coming to the United States she became connected with the Harvard Observatory, one department of which she is at present in charge. Beginning with the simplest forms of computations, the responsibility of her position increased every year, until now she has a splendid record as an astronomer. She has charge of a corps of women assistants by whom the stars are studied in the daytime by the aid of photography, in the same way as by night through the telescope, and by whom the observations made by the meridian photometer since 1888 have been discussed. Mrs. Fleming, from her examination of the spectra of stars, of which she has examined over a million, has achieved distinction as a discoverer, having increased the number of known stars whose spectrum is of the third type from about 1,000 to 3,000, while of the rare class of stars of the fifth type the number has been raised from 16 to 67. "At no other observatory have any stars of the last-mentioned class been discovered during the last eleven years," says Professor Pickering. She has furthermore discovered 54 new variable stars by means of the bright hydrogen lines in their spectra, and in each case has proved their variability from photographic charts of the same regions. In 1890 she was able to announce, from its spectrum, that a certain star in the constellation Cygnus was variable. She also has the honour of having first discovered planetary nebulae by the aid of photography, while in 1893 and 1895 she made the remarkable discoveries of new stars in the constellations Norma and Carina. Besides numerous contributions to astronomical periodicals, she has aided in the preparation of several volumes of the *Annals of the Observatory*; her signature has appeared from time to time in the *Astronomische Nachrichten* and other astronomical journals. Her name is well known among European scientists. The Observatory has called her a brilliant discoverer.

The application of photography to astronomy has wonderfully increased the opportunities for women. The most

* The same result can, I think, be obtained by immersion of the exposed plate in an extremely dilute solution of potassium bromide, after exposure and before development.—E. J. W.

ended application of the aid of women in this speciality has been under the Directorship of Professor Edward Pickering at the Harvard Observatory, where a large force of women are constantly employed under the supervision of Mrs. Williamina Fleming. She is in charge of the department for the examination of views and of photographic plates taken with the Draper telescope. In the course of this examination Mrs. Fleming has made a large number of discoveries of variables, and has connected the discovery of several new stars. Mrs. Fleming is assisted in this work by Miss E. F. Leland and Miss A. Maury, who have made a detailed study of the spectra of the eight northern stars, also by Miss M. C. Stevens and Miss L. Wells, all of whom are women having more than one discovery to their individual credit. The observatory has a corps of about forty assistants, seventeen of whom are women; twelve of these are engaged more or less on photographic work.

Photographs obtained with the various telescopes now in use at the Harvard Observatory are of various classes. The most important of these are chart plates, having exposures of from five to sixty minutes; spectrum plates having the same exposure and heat plates having several exposures of a few seconds duration. Women assistants are not engaged during the night in taking photographs, but find their time during the day efficiently occupied in examining, measuring, and discussing them, and in the various computations therein involved. The most important work at present along this line is being done in the chart plates taken with the eight-inch Draper telescope. This consists in the measurement of stars for standard stellar magnitudes. Measurement of about forty thousand stars are now being made by Miss Eva F. Leland, Miss L. D. Wells, and Miss C. S. Stevens, and have shown great accuracy in making the identification of stars shown in the photographs with those contained in existing catalogues. Photographs of stellar spectra are all carefully examined in order to detect new stars of interest, such as 3rd, 4th, and 5th type stars, or those whose spectra consists mainly of bright lines. Many interesting discoveries have been made from the study of these photographs of stellar spectra. First in importance was the discovery made by Professor Pickering that Ursa Major is a close binary star, the components revolving around each other at a velocity of about 100 miles a second in a period of about fifty-two days. This discovery led to the finding of a second object of this class, namely Auriga, by Miss A. C. Maury. Micrometric measurements of the lines in the photographic spectra of the bright stars have been made by Miss Florence Cushman. From an examination of the photographs of stellar spectra, thirty-eight stars having spectra of the fifth type have been added to the eleven previously known, making the number now known forty-two in all.

Over thirty years ago Lewis M. Rutherford began in New York City his experiments in astronomical astronomy. He continued his work for over twenty years. His best photographs were taken with a refracting equatorial corrected for chemical rays of light. This telescope was 11½ inches in aperture, and had object glasses, one for seeing and the other for photographing. He used wet plates entirely. Mr. Rutherford devised and constructed his own machine for measuring the star plates. This was arranged so as to measure the position, angle, and distance of every star on a plate from a known central star. In 1890 Mr. Rutherford gave all his best negatives to Columbia University. When this collection of negatives was turned over to the Observatory it was arranged to have the work of reduction of the measurements of the star plates pushed forward as rapidly as possible. Mr. Harold Jacoby, assistant at the observatory, undertook the reduction of the Pleiades plates. Rutherford Stuyvesant, son of Mr. Rutherford, although not interested in science himself, gives 1,000 dols. every year to pay the expense of reduction and publication of results of the

Rutherford negatives. The women computers have charge of this work.

Notwithstanding the various ways in which the preceding sketches reveal woman's application of thought and energy to the cultivation of astronomy, nothing has been of such aid to its development as the unbounded liberality of some of our American women. The most notable patronesses are Mrs. Henry Draper, of New York City; Miss Catherine Bruce, of New York City; and Miss Alice Bache Gould, of Boston.

Dr. Henry Draper, in 1872, was the first to photograph the lines of a stellar spectrum. His investigation, pursued for many years with great skill and ingenuity, was most unfortunately interrupted in 1882 by his death. Early in 1886 Mrs. Draper made a liberal provision for carrying on this investigation at the Harvard Observatory, under the direction of Professor E. C. Pickering as a memorial to her husband. She gave several instruments, and contributes 10,000 dols. annually for the work of this department. Owing to the extensive field of investigation in this branch of astronomical physics, Mrs. Draper has decided to greatly extend the original plan of work, and to have it conducted on a scale suitable to its importance. In this work Dr. Draper's 11-inch photographic lens is used, for which Mrs. Draper has provided a new mounting and observatory. There are also at Cambridge a 28-inch reflector and its mounting, also a 15-inch mirror, both gifts of Mrs. Draper. In the observatory there is a central room where the comparison of charts and photographs is carried on. This is known as "The Draper Memorial Room."

The most unbounded liberality so universally bestowed by Miss Catherine Bruce upon every branch of astronomy in all parts of the world will make her name go down in future ages as worthy of unlimited admiration. One can hardly pick up an astronomical publication in these days without finding a mention of some new gift from her to astronomy—250 dols. to purchase a small instrument for a zealous astronomer in a far-away island of the sea; 25,000 dols. to aid in the removal of a vast observatory to a better location; 15,000 dols. to pay for printing various valuable astronomical researches; 50,000 dols. to purchase a new photographic telescope. These are but a small portion of her benefactions bestowed with so much wisdom as to make the first gift no less acceptable than the last. Miss Bruce has been called "the Maecenas of Astronomy." Her intelligent generosity knew no limits of race or country. Her kind and thoughtful care lightened many a burden in her own land and helped to finish many a task where patience and other resources were nearly gone. To Professor Max Wolf, at Heidelberg, she gave 10,000 dols. for a telescope. With this instrument he discovered a new asteroid and named it "Brucia" in honour of Miss Bruce.

Harvard and Columbia seem to have been the institutions which have gained most through Miss Bruce's liberality. To the former, from time to time, she gave 50,500 dols., and to the latter 14,100 dols. Her donations to astronomy in ten years, from June, 1889 to Nov. 29, 1899, amounted to 174,275 dols.

Miss Bruce was born January 22, 1816. Her home was in New York City, where she died March 13, 1900. She was a daughter of George Bruce, the famous type founder. She was an accomplished woman, having a knowledge of Latin, Greek, French, and Italian. She was for many years an invalid. She has left a gracious memory of good and generous deeds, and an impressive example of noble womanhood.

ANNE P. MCKENNEY.

We understand that an addition to our monthly literature will shortly appear in the shape of "The Optical Lantern and Cinematograph Journal"—the title of which sufficiently discloses its purpose. In it are incorporated "The Optical Lantern and Photographic Enlarger" and the "Lantern World." Mr. Theodore Brown will be the editor.

GEOLOGICAL PHOTOGRAPHS.

In the course of a recently published article on this subject, "Nature" remarks that geologists will welcome the second issue of photographs by the committee of the British Association, appointed for the collection, preservation, and systematic registration of photographs of geological interest. The value of these illustrations, both for teacher and student, is beyond question; indeed, as furnishing material for comparative study they may not infrequently prove useful to the investigator also; it may not perhaps be regarded in the light of a compliment when it is added that there is at least one university professor who makes them serve for examination purposes, but this is a perhaps too practical inquisitor, who, when weather permits, sets his examinees in front of previously unseen sections in the field. Every student, not to say teacher, of geology should have seen most of the phenomena somewhere or other which these photographs display, but it is very possible that not everyone has; it is even possible that some geologists have not seen a cirque, an esker, and a pitchstone-lava flow, i.e., not all three. Nothing, of course, can be a substitute for direct observation, but these photographs are certainly the next best thing to it.

Their value is greatly enhanced by the fact that the descriptions have in each case been entrusted to a specialist familiar with the structure illustrated; we need only refer to Profs. Bonney, Lapworth, Marr, Watts, and Garwood, not to mention many other familiar names, to show that the scientific description of scenery has been placed in the best of hands. The subjects chosen for illustration cover a wide range; the Scur of Eigg, with its old lava flow filling a valley now exalted into a conspicuous hill, is shown from a point of view not often selected, and with excellent effect; the column of the Hemlock stone, very reminiscent of the Sahara, offers an admirable illustration of wind abrasion, though it is said to have been at one time mistaken for a sea-stack; a cirque in Bala rocks is interesting both in itself and on account of the associated glacial and fluvial phenomena; the Cheddar ravine is a good example of an unroofed subterranean stream; and a boulder of Silurian rock resting on a glacially polished pedestal of mountain limestone affords a proof of the comparatively trivial amount of subaerial denudation which has taken place since the close of the Glacial period; the cliffs of Muckross, an excellent study in jointing, here, as sharply shown as in a text-book diagram; the raised beach at Saunton Down End, near Barnstaple, is probably one of the finest examples of such beaches to be found in the British Isles; the classic unconformity of Old Red Sandstone on Silurian rocks at Siccar Point, referred to by many of the old masters, and figured by Lyell in his "Elements," is well described by Prof. Lapworth; there is a good example of metamorphism produced by the great Whin sill; the rumbling hole in the ravine, Glenariff, co. Antrim, is a triumph of the photographer's skill.

THE Affiliation Lantern Slide Competition, 1904.—The second lantern slide competition has been supported by forty-seven affiliated societies, 663 slides by 245 members having been entered. The number of societies submitting slides by six or more members, and therefore competing for the certificates of distinction, was 21 with 480 slides by 182 members. The judges have awarded the six plaques to the following slides:—"A Stormy Sunset," W. A. I. Hensler (Hackney Photographic Society); "In the Market Place," F. E. Roope (Hackney Photographic Society); "Repairs," Henry Wright Dick (Manchester Amateur Photographic Society); "At the Smithy," Edgar G. Lee (Newcastle-on-Tyne and Northern Counties Photographic Association); "A Norman Crypt," J. W. Hodges (London and Provincial Photographic Association); "Becalmed," Rev. H. O. Fenton (Devonport Camera Club). Certificates of distinction for the average excellence of the slides submitted have been awarded to the following societies in the order named:—(1) Hackney Photographic Society; (2) Manchester Amateur Photographic Society; (3) Newcastle-on-Tyne and Northern Counties Photographic Association.

Exhibitions.

BRENTFORD PHOTOGRAPHIC SOCIETY.

THE Brentford Photographic Society is not one of those societies which make their importance felt in the photographic world by reason of the great works of its members, though it has one or two members whose productions are not beneath recognition at the Royal, but it has an extremely energetic hon. secretary, who, amongst hon. secretaries of photographic societies is *facile princeps* at beating the drum. It is before the time for sending in exhibits to the annual show readers of our own pages, and those of our contemporaries, will perhaps have noticed in the columns devoted to correspondence pointed reminders of the existence of the society, and the imminence of its exhibition. "Owing to a printer's error in our prospectus the last moment for entry in the Brentford exhibition is made to appear as 7.30 p.m. on such and such a date; it should be 7.35 p.m.," and so on. We far from deprecate this method of procedure. It shows, at the least, a spirit of enterprise which many societies which should be of far greater importance than these are, would do well to imitate. At the worst it does no harm in the world, while in the limited sphere over which the Brentford Society spreads its influence, it does good by attracting attention from people who might otherwise pass it by.

The exhibition was held on the 15th, 16th, and 17th instant, at the Public Baths, Brentford. A large preponderance of the exhibits were in the open classes, the society itself taking but a modest part in the show. On the whole it was an interesting collection of pictures to those who, unlike ourselves, have not met the same photographs over and over again during the past season. In the open classes the best picture was "In the Height of the Storm," by F. J. Mortimer. The "Cod and Lobster Staithe," by G. B. Clifton; "Sweetly They Slumber," by C. D. Kay; "November and Poole Harbour," by H. Wild; "A Winter Afternoon" and "Bankside," by G. H. Capper; "Autumn Sunset," by D. M. Fillshell; "Weary They Wend Their Way," by E. P. Taylor; "Autumn," by F. C. Stear; "The Church on the Mount," by "June," by A. and F. Read; "Rolling Mists," by George J. Wightman; "Eventide," by J. H. Latham; Mrs. Holmes' figure studies "A Study," by Gerald K. Rule; "Morning Service," by T. A. Swaine; "Ettie," by A. & F. Read; "Norman Work, a contrast," and "Quoniam Dilexi," by Rev. H. R. Campion; "Crypt d'Aquilon, Mont St. Michel," by Percival W. Crane; "The House of Prayer," by S. Kimber; "Entrancé to the Undercroft, Wells," by J. W. Gregg; "A Pillar of the Church," by A. Marshall; "Vestibule, Undercroft, Wells," by A. Bedding; "Crypt, Winchester," by W. A. Clark. The flower and fruit study class was particularly good, among the best being that by Miss M. C. Eames, M. Barritt, J. Hummel, A. W. Walburn, H. Cross, and S. G. Kimber.

In the members' classes Miss M. A. Newlands appeared to have the most promising future among those who have not already made a name for themselves. The judges were Messrs. R. C. Bayley, J. Craigie, and J. C. S. Mummery.

The Awards.—Members' Classes.—Landscape: Award, Miss M. A. Newlands; commended, Miss M. A. Newlands, and A. & F. Read. Other Subject: Award, H. Gordon Stollard. Beginners' Class: Award, Miss M. A. Newlands; commended, G. J. Baker.

Open Classes.—Best Picture in Exhibition: Gold Plaque, F. J. Mortimer. Landscape: Silver Plaque, J. B. Johnstone; commended, D. M. Fillshell, and A. and F. Read. Portraiture, etc.: Silver Plaque, A. Marshall. Architecture: Silver Plaque, Rev. H. R. Campion. Bronze Plaque, W. A. Clark. Flower and Fruit Studies: Silver Plaque, Miss M. C. Eames; Bronze Plaque, A. W. Walburn. Landscape Slides: Silver Plaque, F. J. Mortimer; Bronze Plaque, A. Bedding; commended, W. H. Joy.

EXPERIMENTS WITH RADIUM.—A Reuter telegram from Vienna dated March 19th, states that at the request of the Academy of Science, the Austrian Minister of Agriculture, in order to facilitate the solution of certain important questions relating to the nature of radium, has ordered that from January 1st last until further notice no trading should be permitted in the residues from the manufacture of uranium colours at Joachimsthal, and that 10,000 kilogrammes of those residues should be reserved for purchase by the Academy, and another 10,000 kilogrammes for M. Curie, the discoverer of radium in Paris. These consignments are to be devoted entirely to the purpose of scientific experiment.

New Apparatus, &c.

The Watkins Print Meter. Manufactured by the Watkins Meter Co., Hereford.

The latest addition to the series of meters made by this company likely to prove as useful to the photographer as its predecessors. It appears to be based on sound practical principles, and allows for variations of light in carbon and other printing processes. A much slower paper than usual is used, darkening in full sight. Only

The segment of the paper is exposed, and its darkening compared with either of the eight tints given. It is strongly made in hard white metal, nickel-plated, and has blue glass dial. The speed of paper and range of tints are suitable for timing process copying, by hanging on side of copy. The gradation of the tints are not so nearly alike as to puzzle judgment, and are in geometrical progression. It is not expensive.

The "Indelible" Background, Manufactured by Marion and Co., Ltd., 22 and 23, Soho Square, London, W.

The new series of backgrounds just introduced by this firm, and named by them the "Indelible," possesses many striking points of excellence that should command a ready sale. They are extremely portable, of a thin light material, but strong, and likely to stand a lot of wear. The two points, however, that commend themselves to us are (1) the background can be folded or creased in any direction, and yet can be easily smoothed out again for immediate use; (2) it can be washed without in any way disturbing the design, which is indelibly fixed in the material itself in the form of a stain. The backgrounds are made in all the usual stock sizes and supplied on rollers. The range of designs offered should commend themselves for the delicacy of tint which, particularly in the cloud and graduated series, are as fine as anything we have seen. They should prove of great use to the pictorialist who moves with the trend of modern high-class portraiture. The colour, too, of the designs is good, being an excellent neutral brown that should reproduce well. The lightness and semi-transparency of these grounds should suggest novel forms of lighting, as the tints are perfectly graduated, with no visible brush marks by either reflected or transmitted light.

The International Printing, Stationery, and Allied Trades' Exhibition will be held at the Agricultural Hall, Islington, London, N., from Saturday, April 30th to Saturday, May 14th, 1904, inclusive.

Through a report appearing in our columns of a demonstration recently given before the Croydon Camera Club, Mr. Hickox, the inventor of the Quta Ferrotype Camera, received an invitation to exhibit the apparatus on the 5th inst., before the members of the Royal Institute, Albemarle Street. The Platinotype Company lent its portrait lamp for the occasion, Mr. W. H. Smith, its originator, being in charge. A large number of photographs were taken at the rate of a little over 1 a minute, the lamp and camera working without a hitch. In order to soften and diffuse the light, a translucent screen was interposed between the sitters and the source of illumination, the latter consisting of five grains only of magnesium ribbon, and which with the rapid lens employed, was found amply sufficient to secure fully exposed positives.

Patent News.

The following applications for patents were made between March 7th and March 12th, 1904:—

Shutters.—No. 5,522. "Improvements in photographic roller blind shutters." John Edward Thornton.

Washing Apparatus.—No. 5,524. "A washing apparatus for photographic plates, films, or prints." Harry Smith.

Portable Dark-Rooms.—No. 5,586. "Improvements in portable dark-rooms for photographic purposes." Amet Meunier.

Squeegees.—No. 5,628. "Improvements in flat squeegees for photographic and other purposes." Alfred William Stainton Sanderson.

Stands.—No. 5,680. "Improvements in and connected with folding stands for photographic apparatus and the like." Johann Becker.

Dish-Rocker.—No. 5,757. "Improvements in apparatus for rocking developing dishes or like trays or dishes used by photographers." Alfred Whowell.

Printing Process.—No. 5,814. "An improved photographic printing process resembling mezzotint." Henry Bennion-Booth.

Printing Frames.—No. 5,894. "Improvements in or relating to photographic printing frames." Clement and George Gilmer.

Base for Sensitive Emulsions.—No. 5,948. "Improved base or support for photographic sensitive emulsions." James Findlay.

Enlarging Camera.—No. 5,962. "An improved enlarging camera." Thomas Peter Bethell.

Photographs.—No. 6,018. "Improvements relating to photographs." Otto Fulton and William Mountstevens Gillard.

Developing Apparatus.—No. 6,059. "An apparatus for developing roll films, cut films, and glass plates for photographic purposes." Charles Roxburgh Wylie.

THE P.P.A. PRESIDENTIAL BADGE.

As we briefly announced in our last issue, the third annual dinner of the Professional Photographers' Association was made the occasion of presenting a commemorative gold badge and medal to the past and present Presidents of the institution. A reproduction of

the design of the latter is here shown. The medal is attached to a handsome badge, which in its turn, admits of being secured to the lappet of the coat. The President's name and his year of office are engraved upon the medal.

Mr. E. J. Thom writes from 15 and 16, Giltspur Street, Holborn Viaduct, London, E.C.—In consequence of these premises being required for the extension of St. Bartholomew's Hospital, I have removed to 9, Giltspur Street, Holborn Viaduct, London, E.C., where all communications should be sent in future.

EASTMAN Kodak Company of New Jersey.—The usual quarterly dividends of 1½ per cent. (being at the rate of 6 per cent. per annum) upon the outstanding Preferred stock, and of 2½ per cent. (being at the rate of 10 per cent. per annum) upon the outstanding Common stock, have been declared by the Eastman Kodak Company of New Jersey, payable on April 1st, 1904, to stockholders of record at the close of business on the 29th February, 1904.

THE approach of spring should induce those photographers contemplating telephoto work (the opportunities for which are unfortunately not so frequent as they might be in this country) to peruse a little work on the subject by the late Dr. G. H. Deller, published by Messrs. Dawbarn and Ward at the price of one shilling. It is a simple and instructively illustrated little compilation, which draws for much of its matter upon the writings of Marriage, Dallmeyer, and several others.

New Books.

"The Real Dickens-Land." By H. Snowden Ward and Catherine Weed Ward. 240 pp. Illustrated. Price 10s. 6d. London: Published by Chapman and Hall, Limited, Henrietta Street, Covent Garden, W.C.

A University Professor, in the pages of a monthly review some years ago, contemptuously described Charles Dickens as "a mere Cockney humourist." The lapse of a third of a century since the great writer's premature death, which was undoubtedly hastened by overwork, has not diminished the interest of the world in his inimitable books, whilst the name of his scornful critic has passed into the limbo of obscurity. In setting themselves the task of tracing the backgrounds against which Dickens placed the characters in his principal novels, Mr. and Mrs. Ward undertook what was obviously a labour of love. If not exactly a life of Dickens, Mr. Ward's chapters, which record the novelist's movements in England, America, and on the Continent, may very well pass for a skeletonised biography. The plan followed was to endeavour to locate the scenes in the various English books, and wherever practicable to illustrate them by means of photographs. Central London supplied Mrs. Ward with many subjects for her camera, which also found employment at Ipswich, Rochester, Tong, Salisbury, and many other places. This notice is being written in the room adjoining that at 26, Wellington Street, Strand, where for many years Dickens worked on "All the Year Round," and one of the views depicts Nos. 24 and 26, Wellington Street, with York Street in perspective. The photographs in general are of good quality, and well attest Mrs. Ward's remarkable industry and ability. We have no hesitation in recommending this handsome and interesting volume to all lovers of Dickens's works. The text is sympathetically written, and with a minuteness of detail which proves Mr. Ward to have made a careful and at the same time discriminating study of his subject. Many of the buildings illustrated in the book, especially within a stone's throw of these offices, have within very recent times made way before the assaults of the municipal improver, and thus Mrs. Ward's photographs are bound to become of considerable historical value. We congratulate the authors on a most interesting production. It is, in our opinion, the best bit of work they have done, and very probably is destined to live as long as the writings of the great master of fiction whom they have made the object of their well-deserved hero worship.

"The Grant and Validity of British Patents for Inventions." By James Roberts, M.A., LL.B. Illustrated. 647 pp. Price 25s. London: Published by John Murray, Albemarle Street.

In his preface the author informs us that his work has been undertaken "to enable the inventor to confine his claims to what can be supported, and to avoid errors in drawing his specification. Under the new procedure," he adds, "there will arise questions of alleged anticipations which hitherto have only been brought to the notice of the inventor during the progress of litigation; the inventor will therefore have to consider such questions in future before the grant is made." Part I. of the book consists of the principles and rules affecting the grant and validity of patents and the practice respecting the amendment of specifications; Part II. deals with abstracts of cases illustrating the applications of the principles; Part III. gives the statutes and rules. Although primarily appealing to inventors, it is doubtful if the latter class will find such a formidable and profound book of much practical value. We incline to think Dr. Roberts will discover his larger clientele amongst patent agents and solicitors. Your ordinary inventor is usually an irritable genius with little knowledge of patent procedure and practice, and loth to submit his ideas to the disciplinary examination of history and precedent. The volume appears to be an exhaustive and painstaking compilation, which should find its way to many shelves in the neighbourhood of Lincoln's Inn Fields and Chancery Lane. The quoted cases should be extremely valuable for reference; and the third section, which appeals directly to the would-be patentee, is so clearly compiled that it might be worth the author's while to reprint it separately for the information of the general public. The book on the whole is of very high value, and will probably rank as authoritative.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

March	Name of Society.	Subject.
25.....	Nottingham Camera Club	Wellington and Ward's Plates and Films and "Cozin" Daylight Developer. Demonstration. Mr. W. F. Slater.
25.....	Plymouth Photo. Society	Members' Lantern Evening.
25.....	Watford Photographic Union	Kodak Printing Papers. Mr. R. Robins
25.....	West London Photo. Society.....	Northumbrian Rambles. Mr. G. Lamley
25.....	Aberdeen Photographic Assoc.....	Norway. Illustrated. Mr. V. C. Blair
25.....	Ilford and District Photo. Soc.....	Colour Sensitive Plates. Mr. Ernest Human.
25.....	Ox'ord Camera Club	Days of my Soldiering. Capt. Henderson.
25.....	Southampton Camera Club.....	Lecturette Competition.
25.....	Birmingham Photo. Society ..	The Use of Bichromate of Potash to Secure Soft Results in the Development of Bromide Prints from Hard Negatives; and Eder's Method for the Reduction of Too Hard Contrasts in Negatives. Mr. H. Vought Cornish
25.....	Royal Photographic Society.....	Carbon Printing. Mr. John H. Gear.
25.....	Devonport Camera Club	The Carbon Process. Mr. W. Clayton.
25.....	Glasgow Southern Photo. Assoc.....	Photography Prize Slides.
25.....	Cricklewood Photo. Society.....	Criticism of Prints, &c.
31.....	Richmond Camera Club.....	Scenes in South Africa during the War. Major F. F. Latham.
31.....	Liverpool Amateur Photo. Asso.....	A Caravan Tour from Palmyra to Damascus. Mr. Harry Mahler.
31.....	Gainsboro' Camera Club	Members' Night.
31.....	Watford Camera Club	Discussion on Outdoor Work.

ROYAL PHOTOGRAPHIC SOCIETY.

TECHNICAL meeting, March 22nd.—Major-General Waterhouse, I.A., in the chair. Three interesting items were announced for the evening—viz., "A New Tripod and Universal Tripod Head Movement," by Mr. C. A. Franklyn; "A New Link between Calculating and Effecting Camera Exposures," and "A New Print Meter," by Mr. Alfred Watkins; and "A Method of Photographing Splashes," by Mr. Arthur C. Banfield.

Mr. C. A. Franklyn's new tripod with universal movement to the head embodies many striking and original features that should make this adjunct to the camera of more than ordinary utility. When closed, the complete stand and head is self-contained, and has no loose parts or straps. The handle is placed at the most convenient point for carrying—viz., at the extremity of the closed tripod; and metal clips, forming part of each individual leg, holds the three together at one end when shut up, and the tripod screw itself clamps the other end.

The tripod when closed is no larger in bulk than an ordinary 4ft. 10in. stand, but its greater extension and variety of movements were ably demonstrated by Mr. Franklyn. The chief point of interest lies in the head itself, which is tri-sected, or, rather, composed of three overlapping parts, each of which is hinged to the top of a tripod leg, the whole being held together with the camera in situ by the tripod screw. The aim and result of this arrangement is that the camera when fixed to the tripod head can be turned in practically every possible direction and firmly clamped without in any way moving the tripod legs and without affecting its rigidity. The principal claims made for the utility of the tripod are that it can be placed on uneven ground and the camera instantly levelled without shortening or otherwise manipulating the legs. The camera retains its horizontal position without altering its height or relative position to the foreground, which is necessary with other forms of tripods, and the tripod can be placed flat against a wall or other obstruction and the camera then pointed in any direction for use.

Mr. Alfred Watkins briefly described his new print meter, which we review this week under the heading of "New Apparatus." He then proceeded to demonstrate a new system of scales of comparative shutter speeds and lens apertures, which he proposed introducing as an accessory capable of being attached to most existing shutters, and to be used in conjunction with them. He criticised and pointed out the faults of many of the shutters on the market, and made it clear that the link between calculating and effecting camera exposures would be supplied by his new slide calculator, which shows at a glance the relation between the shutter speed and stop, and

means of a series of moving scales on the shutter itself (the method would be most applicable to shutters of the diaphragmatic type), the movement of one pointer would not only set the shutter at the requisite speed, but also alter the diaphragm to the required aperture, the relation between any stop and speed being ingeniously indicated by the scale when once the light value and required exposure for any one stop had been ascertained.

Mr. A. C. Banfield showed first a series of slides depicting the descent of a roughened sphere into milk, and then a companion series showing the result when a polished steel ball was employed. The difference was very marked.

This beautiful series of representations of splashes taken at exceedingly intervals of 1-250th sec. showed the complete phenomenon in the instant the sphere was released, to the formation of the initial ripples in the fluid after it has disappeared from sight; its contact with the liquid, its immersion, the immediate effect on the liquid surface, and the different phases of the splash.

All were disclosed with startling realism, but the series, as a whole, would have been beyond the power of the human eye to follow and perceive during the actual occurrence of the operation.

The photographs, Mr. Banfield explained, were obtained by means of an electric spark obtained from Leyden jars in connection with a release apparatus of his own construction. An ingenious clockwork arrangement allowed for a variation between the release of the sphere at the instant of exposure, as minute as 1/1,000 of a second, and throughout the series depicted showed a series of different splashes, the adjustment of the timing arrangement was so perfect that the continuity of the photographs was unbroken, and each showed a splash at a period of 1/250 of a second later than its predecessor.

CAMERA CLUB.

Fortnight ago, in our "Ex Cathedra" columns, we gave a brief account of a method of photo-sculpture, which had been shown at a meeting of the Royal Institution. At that time it had not been announced that Signor Carlo Baese, the inventor and patentee of the process, had consented to lecture on the subject at the Camera Club, possibly we should have refrained from dealing with the matter in view of the later opportunity presented for placing it in a more complete form before our readers. The lecture was given on Monday last week, and it attracted a considerable audience, for the earnest amateur photographer is ever on the look out for novelties, and this one also well worth the attention of professional photographers, for the public, too, are keen for things which are new, and the idea of finding a new image in relief on a plaque, or on a medal, is one which will certainly appeal to many, who had no notion of finding their features reproduced in such unusual and imperishable form. The image and inscription of Cæsar becomes by this invention within the grasp of man in the street. It is known to all photographers that a certain amount of relief is possible with an ordinary gelatine plate, especially if the film be treated with some hardening solution so that it can be developed by heat. Upon a negative so produced we can, by reflective lighting, see that various parts of it stand up much higher than others, and many will remember that some years ago Sutton's method of making printing blocks from ordinary negatives depended upon this phenomenon. A large measure of relief is obtained by printing on film of bichromated gelatine, as in the Woodbury process. But by the other method it is possible to get, without further help, a bas-relief which is in any way comparable to that formed upon a medal made by the die-sinker's art.

Signor Baese makes use of swelled bichromated gelatine as a printing medium, but he first of all takes a negative, or rather two negatives, under new and special conditions of lighting. Two methods of doing this he described in his lecture. In the one he employs two electric projecting lanterns to light up—say, the profile head of the sitter, placed upon either side of the model. Each of these lanterns stands up the sitter with what we may describe as an optical wedge. That is to say, each lantern is furnished just in front of its condensing lens with a vertical moving strip of opaque film, which is cut with a series of Vandyck's, or horizontally-placed V shaped openings. In making the first negatives the wedge-shaped beam of light is so angled that the nose and back parts of the head receive the widest parts of the slice of light, the ear and the forward portions being least illuminated. This exposure having been completed, the arrange-

ment is reversed, and this time the forward portions receive the most light, and the back ones the least. Positives are then made from the two negatives, and these combined are used for impressing, by means of light, a bichromated gelatine film. If one negative only were used the colours of the hair, eyes, etc., would present a difficulty, for their dark shades would be translated into relief, which would be untrue to Nature. By taking two negatives as explained this difficulty is altogether obviated, and the disturbing colours are ignored.

An alternative and better plan is to use only one electric lantern, which is placed by the side of the camera in front of the sitter. In this case the wedge of light, by a modification of the travelling film with its >-shaped openings, is received on a section of a parabolic reflector, which is placed around the sitter's head and bust, so that it is reflected with the same graduated effect upon the various parts of the model. The exposure is about the same as that for ordinary portraiture under daylight, and the change in the apparatus necessary between the taking of the two negatives is almost instantaneous. Signor Baese at first employed wedges of coloured glass, in order to secure the necessary graduation of the light, but doubtless because of the refraction difficulties he abandoned that plan and adopted the opaque film, with >-shaped openings as described.

Signor Baese, as was explained by the chairman, Sir H. Trueman Wood, laboured under unusual difficulties in giving this lecture; for, although his linguistic powers are such as most of us would envy, English is not his strong point. He could have easily talked in French, German, or his own native Italian, but out of good nature and compliment to those whom he addressed, he spoke in English. He was kindly helped by the chairman out of the pitfalls which our grammar prepares with such prodigality for the benefit of foreigners, and Mr. Gordon, who had had the advantage of a previous private audience from the inventor, was able to give a succinct account of the process as an addendum to the lecture. By means of his valuable help sundry points were made clear, and the meeting acknowledged its indebtedness for the assistance afforded. The paper was illustrated by various lantern slides, some diagrammatic, showing how the amount of relief was governed by the quality of light which each portion of the face received in addition to which were several photographs taken from plaster casts and metallic plaques. These plaques were subsequently handed round, and they excited much interest among those present. It was the general impression that these were not the best results which could be obtained from the process in the hands of an expert worker. Signor Baese does not pretend to be a skilled photographer, but he has given all his time and attention to proving that his process is based upon reliable data, and that it is a practical success. We presume that he will presently be in a position to put the necessary apparatus upon the market for the use of all who desire to practise modelling by the aid of photography, and from what we saw, we should judge that the necessary equipment need not be an expensive one. The arc-light is, of course, a necessity, but in these days of electric mains its production in most towns is not a matter of difficulty. The method is one of much promise, and we feel confident that when it is made available to experienced photographers it will be improved, if not made perfect.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the General Committee was held at 51, Baker Street, W., on Friday, 18th inst. Present: Messrs. Alfred Ellis, Wm. Grove, J. A. Bridge, H. Edmonds Hull, A. Mackie, and Lang Sims, Mr. Alfred Ellis, President, in the chair. Mr. Lang Sims informed the meeting that every member of Committee had subscribed to the fund for providing gold badges for the present and past Presidents of the Association. After paying for the three badges which were presented at the annual dinner, a balance remained. It was decided that this should be handed to the hon. treasurer, to be applied to a similar purpose on another occasion. The accounts for the annual dinner were presented and passed. A discussion took place upon the eligibility of a candidate for membership. It was decided to bring the matter again before the Committee for a definite pronouncement as to bearing of the rule in similar cases. Letter read from the Fine Art and General Insurance Company, in reply to an inquiry, explaining that the arbitration clause contained in their policies provided that the costs of the arbitration be borne by the unsuccessful party, and was therefore free from the objection that had been

raised to the clause which appeared in the policies of most fire insurance companies.

Various applicants for advice, etc., and other matters which cannot be reported were dealt with. The honorary secretary reported the progress of the Derby Exhibition. It was decided that if sufficient applications for space were not received to fill the exhibition the Committee should issue personal invitations to members whose work might be considered typical of modern professional photography. The proposed foundation of an Examining Board for assistants was further discussed, and progress made.

RICHMOND CAMERA CLUB.

MARCH 17TH.—Mr. Walter P. Watmough, on behalf of Messrs. Burroughs, Wellcome, and Co., of that firm's system of putting up photographic chemicals in tabloid form. Mr. Watmough showed first the results of toning and intensification of lantern slides by means of a series of slides prepared and treated with tabloids. He then explained that his firm do not make any claim to secret or mystical formulae, but simply to the production of tabloids containing the purest chemicals in a form most convenient for mixing at the time they are required for use without the trouble of weighing the different constituents of each formula, and thus saving the necessity of keeping stock solutions which are in many cases liable to deteriorate. He then gave a practical demonstration of toning black and white lantern slides and bromide prints with tabloids containing copper sulphate, potassium ferricyanide, and a neutral citrate. The plates and prints were immersed in a solution of these tabloids, and in a few minutes the cold black and white tones were changed into warm brown. This was followed by intensification of a thin film negative by the use of mercuric iodide with sodium sulphite. The film was cut in two for the purpose of comparison and one half, after immersion for a few minutes in the intensifier, was re-developed with an alkaline developer. A comparison of the result with the non-treated half of the film showed that the printing quality of the negative had been very greatly improved.

CROYDON CAMERA CLUB.

MARCH 9TH.—"Slow Plates for Short Exposures" formed the title of a most interesting and original paper, read by Mr. C. E. Kenneth Mees, an added interest being given the lecture by the fact that Mr. Mees and his colleague, Mr. S. E. Sheppard, have recently gained distinction for themselves, and the club, by obtaining the first B.Sc.'s for original research work in photo-chemistry. In the space at our command it is only possible to epitomise the salient features of the lecture, and the general conclusions to be drawn from it, which may be summed up as follows: "That, disregarding certain types of subject, and in reference to the period of under-exposure only, slow plates, within certain limits of speed, will give better practical results than rapid, or ultra rapid plates; and that, with a given exposure below that correct for the fast plate, the slow plate will in all cases show as much detail, and, in addition, owing to its inherent qualities, will render a far better negative judged by ordinary standards." Granted that the slow plate will give all detail possible with the fast plate, then the reason for its superiority in other directions is not hard to find. The slow plate generally has a higher γ , or, in other language, will develop to a greater density with infinite development. It has also a higher κ , or rate of development, together with great freedom from fog on prolonged development. Now, the length of useful development depends upon freedom from fog, and with a fast plate fog steps in comparatively early. From general conclusions, no doubt there must be a cardinal difference between the negatives produced under the circumstances stated, but the difference in landscape-lit subjects would not be perceptible to the eye. Mr. Mees specially excluded certain subjects from his dicta, such as may be met with in portraiture and interiors. These, as a rule, presented much greater relative contrasts than the average landscape, if the sky portion be omitted.

The lecturer's attention was first drawn to the matter almost by accident. In an attempt to devise a simple scheme for approximately ascertaining plate speeds without resource to exact measurements and instruments of precision, he constructed a negative, or rather six little

negatives, on one plate, of equivalent density, the plates to be tested being exposed behind, for various predetermined periods to a standard light. He soon found that with slow plates, owing to their latitude it was impossible to say which exposure was best; the length of development having such an important influence. The eye was, in fact, insufficient, and although a photometer might have been brought into service, this would naturally have defeated the object in view. He next tried developing all tested plates to infinity, and then found that the fast and the slow were, in the lower part of the exposure identical so far as detail was concerned. The plates tested had rates of speed from 1 to 5 to 1 to 8. A series of tests in the camera followed, which confirmed his previous observations, the slow plate also, for the reasons before stated, always giving the better negative. There was, however, a limit of speed for the latter, which should not drop much below 20 H. and D. Mr. Mees then showed on screen a series of negatives on half-tone and rapid plates, in all cases under-exposed for the fast plates, which amply bore out what he had advanced. Particularly noticeable were focal plane studies, exposed 1-500 second at F. 8, day dull, on Ilford half-tone plates, as against a special rapid plate. Normal snap-shot exposures on Thomas's lantern plates showed all detail, but the negatives were "ghosts," and unprintable. Mr. Mees concluded his lecture by a series of graphic demonstrations, showing the relationship between development, infinity, and rate of development, and the influence of bromide. In addition of the latter might be equivalent to dividing the speed of the plate by about 5. He also expressed a warm debt of gratitude to the president (Mr. S. H. Wratten, unfortunately absent through indisposition), for much valuable assistance and interest he had displayed. The vice-chairman (Mr. E. A. Salt) had also never spared criticism. A most hearty vote of thanks was accorded to Mr. Mees.

During the evening Mr. Dunmore kindly presented to the club his capital pictorial studies, handsomely framed, two of which had received medals at the R.P.S. The vice-chairman suitably acknowledged Mr. Dunmore's generous gift.

ULSTER AMATEUR PHOTOGRAPHIC SOCIETY.

DR. CECIL SHAW, M.A., one of the original founders of this Society, delivered a lecture on Monday last, before the members of the Society, at the Museum, College Square North, Belfast, entitled, "Some Recollections of Twenty-Four Years of Amateur Photography." The lecturer dealt in a lucid fashion with his photographic experience during that period, and conclusions from them as to different forms of photographic apparatus and processes, and concluded by giving some hints as to economy in working. Dr. Shaw's lecture, which was followed with attention by those present, occupied half the evening, giving time for an interesting lecturette by another of the members, Mr. J. Backhouse, on some of the "Early History of Photography in England, 1840-43." Through the kindness of a friend, a Mr. Henderson, of Reading, Berks, some of the first prints produced in England, about the year 1841, by Mr. Fox Talbot and his assistant, Mr. Henneman, were shown to those present. Mr. Henderson's father and a young fellow named Harrison, about 1840, were apprenticed to Mr. Lovejoy, a stationer and librarian in Reading, where Mr. Henneman used to purchase paper for experimenting with, and often gave the two lads copies of the prints he had taken. Harrison was a methodical young fellow, and pasted his photographs in a scrap-book, which at his death passed on to his son. The prints, with notes, are authenticated by Sir Benjamin Stone as a genuine work of the late Fox Talbot, which lends an additional interest to them. Mr. Lovejoy's library for fifty years was the resort of all the literary and scientific people who visited Reading, amongst others, Lord Brougham, Mary Russell Mitford, the authoress, was at the height of her popularity, and many brilliant conversations the young apprentices had the pleasure of hearing between her and such well-known people as Lord Brougham, Talfourd, Charles Dickens, Mrs. Trollope, the Howitts, and many others; hence it came about that everything new or interesting was generally known there so soon as it became public. When, on a visit to the Lake of Como in December, 1833, Fox Talbot made his first discovery of producing "sun pictures" through observing certain effects caused by passing clouds upon the shores of the lake. On returning home he carried out a series of experiments, which con-

ed him it would be possible to produce such pictures upon initially-prepared paper. By the year 1839 he had obtained a correct recognition of what he termed the Calotype process. Daguerre and Mr. Fox Talbot to make efforts for further research, and in 1840 or '41 he engaged a Dutchman, Mr. Nicholas Henneman, who took up his residence at Reading, as being a convenient place of call between Chippenham and London, on the newly-opened Great Western Railway, to make further experiments, and as far as possible perfect the process. Henneman was nothing like the typical Dutchman, but a lively volatile fellow, who had lived much in Paris, and was more of a Frenchman. Although at that time, knowing several foreign languages, he was rather deficient in English, and soon became known to him he was glad of my help in assisting with his growing correspondence (writes Mr. Henderson), being employed to copy Mr. Talbot's MSS. At first his visits to our shop all sorts of writing papers, and then going to a well-known chemist for various chemicals not in general use, soon aroused suspicion as to his vocation. He lived alone with an old housekeeper, a tolerably good house, which had been a school, where there was a large room without windows, but a skylight. This he used for his experiments, and always kept securely locked. Prying neighbours and others soon came to the conclusion that he was engaged forging foreign bank notes or some such nefarious pursuit. But for some time, Harrison, myself, and the chemist's assistant, Tom one, were invited by him to spend an evening with him, when he showed us all the nature of his occupation, and explained what he was engaged in endeavouring to accomplish. It was during this visit (1841-43) that all the specimens I have mentioned as being in existence were produced, and therefore there cannot be any doubt as to their genuineness. It was about this time Mr. Fox Talbot made it known that it was not his intention to take any steps to secure to himself any advantage he might make from his discovery, and one day meeting our county member, Mr. John Walter, chief proprietor of the "Times," who was a constant visitor at my shop, he explained the whole thing to him, and within a short time an article appeared in the "Times" making the process known, a free gift to the whole world. Years afterwards Henneman the operator for Sarny at Scarborough. Mr. Henderson, in connection writes:—"I much regret I did not make a study of photography to some extent. For forty-five years my business engagements necessitated my visiting almost every town in the United Kingdom. It has brought me into contact with people in all stations of life, of almost every caste or historical building, and every cathedral in our dear old land."

News and Notes.

YORKSHIRE Photographic Union.—The annual meeting and exhibition of prints will be held in the Church Institution, Westgate, Wakefield, on Saturday, April 23rd, 1904.

MESSRS. J. J. GRIFFIN AND SONS, LTD., write us that they have taken part in the forthcoming Northern Photographic Exhibition. They have a full range of their cameras and printing papers on view.

We have received a catalogue of second-hand and shop-soiled photographic apparatus from The City Sale and Exchange, 90-94, Fleet Street, London, E.C. It is full of good things, and should be in the hands of every amateur and professional desirous of picking up bargains for the coming season. The catalogue will be sent free on application.

The new paper, "London Opinion," which appeared on March 24th, under the control of Mr. A. Moreton Mandeville, should prove a successful journalistic venture. For the expenditure of the first penny reader obtains contributions from Mr. T. P. O'Connor, M.P.; Mr. George R. Sims, the Rev. R. J. Campbell, M.A.; Mr. A. G. Hales, and Mr. C. E. Humphry, Mr. T. Sharper Knowlson, Sir Henry Cotton, and others equally well-known to literature and art.

We have received a very complete illustrated price list from Messrs. Jones and Co., of Ealing, W. They specialise in bromide and carbon enlargements. Developing, printing, toning, retouching, etc., for

amateurs and professionals, they make a feature, and will undertake any kind of photographic work from picture postcard making to framing exhibition prints. The catalogue is a handsome production, and all interested should obtain a copy.

An exhibition of photographic portraits by Mr. William Crooke, of Edinburgh; Mr. Fredk. Hollyer, of London; and Mr. T. C. Turner, of Hull and London, was opened at the Royal Photographic Society's house, 66, Russell Square, on Tuesday last, the 22nd inst. The exhibition, which includes some fifteen examples by each of the above, will remain open for some six weeks at least, and may be seen between the hours of 11 a.m. and 6 p.m. Non-members are invited to view the exhibition.

To Architectural Workers.—At an instruction lecture given by Mr. S. H. Bentley, on the 16th March, before the members of the North Middlesex Photographic Society, an excellent suggestion was made whereby the difficulty of inserting the dark slide when working close up to a wall could be overcome. He recommended that the reversing back should be made to fit three ways instead of only two, as customary, and this will enable the worker to insert the slide either from the right or the left.

MR. RICHARDSON EVANS, hon. secretary of the National Society for Checking the Abuses of Public Advertising, has written to call our attention to the weakness of the English Municipal Law in regard to lack of initiative in dealing with some of the modern advertising eyesores that offend on every side in our cities, and more particularly in the country districts. He draws attention to the go-ahead policy adopted by the New Zealand Legislature in dealing with the matter, and quotes several acts which regulate the abuses of public advertising in that colony.

COXIN Competition.—Messrs. W. Butcher and Sons announce a monster competition of the picture-puzzle type now so popular. It has been inaugurated in connection with Coxin, the daylight system of developing plates and films. Sixty-eight prizes will be awarded, ranging in value from a Humber motor bicycle, and a Riley's combined billiard and dining table, to cameras at various prices. The dealers who supply the bottles or tins to the competitors who are successful in winning the first five prizes, will also receive duplicate prizes. Application for particulars should be made to Camera House, St. Bride Street, E.C.

ASTRONOMICAL Photography at Yerkes Observatory.—Mr. G. W. Ritchey of Yerkes Observatory, has surprised his astronomical friends by the fine photographic work he has been doing recently by the aid of the great 40-inch refractor, and the two-foot reflector. Some of the reproductions of photographs of prominent features of the Moon are themselves little less than perfect. "Mare Serenitatis Mare Tranquillitatis" and "Mare Nubium" are examples. If the reproductions from the original negatives, by a screen of 200 probably, produces as fine and natural effect, the negatives themselves must be better. Yerkes Observatory may well be proud of such photographic work, for we doubt if it is excelled anywhere.—"Popular Astronomy."

IPSWICH Camera Club.—A camera club has been formed at Ipswich. The following are the officers of the new society:—President, Mr. G. Calver Mason; vice-presidents, Messrs. W. P. Stericker, F. W. Goffin, C. F. Hunnibell, J. D. Sims, R. H. Sutton, and Dr. Ward; hon. treasurer, Mr. G. H. Hewetson; hon. secretary, Mr. R. H. Sutton; assistant hon. secretary, Mr. P. W. Elkington; hon. lanternist, Mr. John Wiggins; committee, Dr. F. Ward, Dr. Hossack, Mrs. Brogden, and Messrs. A. J. Leighton, J. C. Wiggins, F. W. Goffin, G. W. Horsfield, — Wright, and W. E. Harrison. The hon. secretary's address is 37, Henley Road, Ipswich, and he will be pleased to receive the names of ladies and gentlemen in the neighbourhood wishing to become members.

YORKSHIRE Photographic Union.—A meeting of the Council was held at the Vegetarian Restaurant, Bradford, on Friday evening, the 18th inst., Mr. Godfrey Bingley in the chair. The ballot resulted in the election of the following officers:—Mr. G. Bingley, president; Messrs. C. B. Howdill, Lieutenant-Colonel R. E. Johnson, V.B., Percy Lund and Percy Sheard, vice-presidents; Mr. Alexander Keighley, F.R.P.S., hon. treasurer; and Mr. Ezra Clough, hon. business secretary. The following gentlemen were elected as the official judges for the ensuing twelve months:—Messrs. G. Bingley, Gilbert Foster, R.B.A., Alexander Keighley, F.R.P.S., Percy Lund, Percy

Sheard, and Harry Wanless. A hearty vote of thanks was accorded to Mr. Lund for his kindness in providing tea for the delegates attending the meeting.

THE annual dinner of the North Middlesex Photographic Society was held on Saturday evening last, March 19th, at the Holborn Restaurant, when the President, Mr. Charles Beadle, who occupied the chair, was supported by a large number of members and visitors, amongst those present being Mr. Douglas English, Mr. J. C. S. Mummery, Mr. Thomas Bedding, F.R.P.S., Mr. R. Child Bayley, Mr. F. C. Tilney, Mr. George Scamell, Mr. J. W. Marchant, Mr. J. McIntosh, etc. The dinner was made the occasion of presenting to the late hon. secretary, Mr. Pring, a handsome clock and a pair of vases in recognition of his services to the Society. In distributing the certificates gained by members who competed at the last exhibition Mr. Mummery suggested that those gentlemen should send work to the open exhibitions. The toast of the Society was proposed by Mr. Douglas English, and in the course of an excellent speech by way of acknowledgment the President emphasised the value of photography as an agency for recording plain facts in contradiction to the use of hand control methods of producing prints—such as gum bichromite. Other toasts were the "Photographic Press," replied to by Messrs. Thomas Bedding, F.R.P.S. (Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY), and R. Child Bayley, F.R.P.S. (Editor of "Photography"). Mr. George Scamell responded for the toast of "The Visitors," and the final toast was that of the musical artists and producers of the menu card, the latter being a most refined and artistic souvenir by Mr. H. Barnard. Musical and instrumental solos contributed to the enjoyment of those present, who united in agreeing that the dinner was one of the most successful of the series of North Middlesex festivals. We congratulate the Society on its prosperous position, and the markedly favourable influence it exerts on the progress of pictorial and technical photography.

NATIONAL PHYSICAL LABORATORY.—On the invitation of the President of the Royal Society and Lord Rayleigh, chairman of the General Board, several distinguished men of science visited the National Physical Laboratory, Bushey House, Teddington, on Friday afternoon (March 18th), for the annual inspection of the departments and apparatus. The visitors were received by Lord Rayleigh and Lord Kelvin. In the various departments there were many things of profound interest to the visitors. Two rooms devoted to electricity contained a Kelvin balance, a bridge for resistance measurements, an electric clock presented to the laboratory by Professor McLeod, an electro-magnet for watch testing, and illustrations of methods for measuring a small resistance. In the metallography department was a Compton one and a half horsepower motor, which drives a hack saw for cutting sections of metals, a Crowell rotary air-blower for various concentric jet furnaces, and a vertical drill. There was also in this room an open-scale potentiometer for differential cooling work and melting-point determinations, constructed by the department. In another room was a polishing apparatus in which three pieces of metal can be polished simultaneously. This was designed by Mr. J. E. Stead, and presented by him to the laboratory. The work of testing yard measures and their subdivisions was seen in operation as well as an apparatus for measuring surveying tapes in sections. Considerable interest was displayed in the tide predicting machine designed by Lord Kelvin and Mr. Edward Roberts and transferred by the Indian Government, whose property it is, to the care of the National Physical Laboratory. The machine has been used for twenty years for the prediction of the Indian tides, and the preparation of the tide tables for 1905 is now in progress. Thirty curves have been run off the machine, and the work of measuring these to obtain the heights and times of high and low water is proceeding. A start has also been made on the work for the riverain ports, in connection with which the machine can only be used to give the correction for the diurnal tides. The inspection of the various rooms proved exceedingly attractive, and did not conclude until after five o'clock.

PORTRAITURE at Home.—To make portraits at home is the ambition of nearly every amateur photographer, whether a beginner or of the more advanced type; in fact, says the "Bromide Monthly," some of the best portraits, from an artistic standpoint, that have ever been made, have been by amateurs. In order to make good portraits at home it is not necessary that we should have a great

amount of paraphernalia: a simple background or two that can be stretched tightly over a support of some kind, or perhaps some way fastened at the top of the picture moulding, and weight at the bottom with a wooden roller of sufficient weight to keep the background without wrinkles. The roller will also answer to stretch the background upon, so as to be easily put away and kept safe. It is well, if possible, to have a dark ground for heads and grow up people, and a white one especially for children, although this may be regulated at will and departed from in special cases. A portiere makes a very nice background, and in some instances lace curtain may be used for a white background; but, of course, the blind behind it must be pulled down. As a general thing, however, a dark background is more desirable, as softer results are obtained than with a light one, and the resulting prints are easier to handle. Of course, our light is the most important part of portraiture; a north light is the most preferred, and, possible, should be selected where it is not obstructed by buildings or trees, as this light will be stronger, and a quicker exposure can be made than where the light is interfered with, although in cases where it is impossible to avoid this the difference can be made up by lengthening the exposure. In making portraits in an ordinary room, we must select a room with as large a window as possible, and cover up the bottom sash, and a little way up the top sash, with some black material, so as to completely block out the light, and thus in a way obtain a top light to a degree. If we have been unable to select a window facing north, we must diffuse the light still more by tacking up white yellow cheese-cloth on the upper sash. Remember that a most important thing to avoid is any crossing of light. All our light must come from one source, or else we will get most disagreeable shadows and a result that will be very unnatural. So pull down the blind of the windows not to be used for lighting our subject. It will also be necessary for us to reflect some light on that side of our subject that is turned against the light, and this may be done by stretching a white sheet over an ordinary house screen; place the reflector slightly in front of the subject—as near as possible, as long as it is not photographed. The reflector may be moved around at different angles, so as to give the most pleasing results. A good plan for a window screen is to hang a dark-green blind upside down—that is, have the roller at the bottom of the window and the cord going over a ring or pulley at the top of the window casing. In this way we can exclude as much or as little light as we wish by simply lowering or raising the blind. In placing the side care must be taken to use a light that is best suited to give the necessary roundness to the face and avoids angles. The eyes should be in an easy, natural position, and not turned to either side, but let them follow the direction in which the nose points. Almost any kind of a double lens is useful in this style of photography, but, of course, good tools make good work, in portraits as well as in any other kind of photography, and especially is it necessary in home portraiture that our lens should work pretty fast—the shorter the exposure the more natural will be the expression of the face of the sitter. Do not try to make indoor portraits with a "single" lens. For if you do, you will lose the friendship of your subject by making him pose for so long a time as would be necessary; and, again, the result would probably haunt you as he does as well. The question of exposure is one that must be learned by experience only; perhaps an exposure meter, such as the Watkins will help you. It depends upon so many different conditions that it is almost impossible to give advice, but a few trials will give us the right idea in this respect, and help us along under any condition that may exist. In placing your sitter, put him, if possible, about 6 ft. away from your window and sideways to it, and about 2 ft. or 3 ft. back from the window, if you can, and do not forget to block out the lower part of the window used, and all of the windows not used. Another accessory that will be found useful is to have a white shade hung from the very top of the window and so that it may be unrolled and brought over the sitter's head on a slant downward from the roller. In this way, a very effective top reflector may be had. In fact, so many different results may be got by a simple manipulation of light by various means that almost any lighting that can be obtained in a regular studio may be had, and it is very much worth one's while to experiment along this line, and the enjoyment will more than compensate us for all the trouble.

Correspondence.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

PATENTS IN AUSTRALIA.

To the Editors.

Gentlemen,—Your readers will probably be interested in hearing that the Governor-General in Council of Australia has decreed, in accordance with the new Federal law, that patent applications for Australia can now be formally made at the Custom House of the principal city of each State. Applications so filed will be marked with date, hour, and minute of receipt, and the applications will be subsequently recorded at the Patent Office as having been filed at that date. Applications thus filed will not be merely taken in order of date, but they will be held to be dated as far as regards novelty in the date of actually filing at the Custom House, unless dated otherwise by the convention. Under the convention nearly all the principal countries and colonies have agreed to grant the right to a patentee who has filed an application for a patent in one of the countries or colonies, to date any or all the other applications he may make for the same invention in other realms during the year, as of the date his original first application. The application in Australia can therefore be a provisional one, or a complete. The fees and stamp duties are just double those of an application for Great Britain and Ireland. Yours truly,

WM. P. THOMPSON AND Co.,
Chartered Patent Agents.

Lord Street, Liverpool.
March 22nd, 1904.

THE ELBOWED-OUT PROFESSIONAL.

To the Editors.

Gentlemen,—Yes; the elbowed-out professional. Is it true that the trend and pressure of the times has squeezed him up to a higher level, above the ordinary shop commercialism? Recently we have had advice tendered to us, and "B. H." has replied thereto. Both are articles have been a treat to read, but for widely different reasons, and I ask your permission, Mr. Editor, to make public a few of my comments thereon. First, "Amateur photographers are to date." What are we to understand by that? Does the "up-to-date" mean in quality, quantity, or cheapness? If the two latter are what the lay public desire, the writer must be satisfied, he gives instances of how rivals compete with each other at bankruptcy prices; but I consider that he has been well replied to by "B. H." Just one more comment: We are advised to take up the "up-to-date" papers. On this point I cannot do better than quote the writer on the same page, No. 195, in March 4th issue, where the following is printed as an "up-to-date" paper:—"The general public is nine unsatisfactory prints out of every ten, and the tenth is probably faded in a month. Better results were obtained in the old days of albumenised paper." No more need be said. On the whole, I agree with "B. H.'s" views until we reach this paragraph:—"The professionals' remissness in allowing the local chemist to capture the dealers' trade." I will put my comment in this form: What would you think of an R.A. who complained of the local colourman using tubes of pigment, brushes, varnishes, canvas, and stretchers, and robbing him of that trade? What presumption! True; but I can thin the analogy down to what degree you choose, the principal remains the same. I had also written some comments on assistants and "free portraits," but in your last issue, on page 222, where these matters were dealt with so ably by your trenchant pen, my humble effort were like skim milk in comparison. Please accept my thanks, in which I feel sure all professionals will join, and I ask them to read the pages again, and wish that all the world would do the same. I wish "B. H." had signed his name and address, I think he is a professional.—Yours faithfully,

W. BARRY.

The Studios, 7 and 8, Park Street, Hull.

"B. H." is a well-known professional photographer, and a member

of the P.P.A. Although always willing to allow our professional readers the opportunity of ventilating their grievances in our pages, we do not see that any good object can be served by the prolongation of a correspondence upon a subject which has so often been discussed in the JOURNAL.—Eds., B.J.P.]

THE NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION.

To the Editors.

Gentlemen,—Would you be kind enough to inform your readers that at the annual meeting of the National Photographic Record Association some of our members undertook to make prints for our Association from any suitable negatives that might be lent to us for that purpose. The Council will therefore be much obliged to any one having such negatives for the loan of them for that purpose, and, in the first instance, would ask for lists of negatives proposed to be sent, so as to be able to make a selection. Every possible care will be taken of all negatives, but the Council cannot hold themselves responsible for any damage.—I remain, yours truly,

GEO. SCAMELL, Hon. Sec.

21, Avenue Road, Highgate, London, N.,
March 17th, 1904.

HOUGHTON, LIMITED.

To the Editors.

Gentlemen,—In your current issue you announce the amalgamation of four firms under the title, "Houghton, Limited." One of these happens to trade in London under the same name and style as ourselves, and we wish to intimate that we are in no way connected with the firm in question or with the combination. We should be glad if you would kindly draw attention to this fact.—Yours truly,

HOLMES BROS.

22, Oxford Street, Manchester.

BROMIDES FOR PLATINOTYPES.

To the Editors.

Gentlemen,—Referring to your article, "Fraudulent Photography," we beg to state that the substitution of silver and bromide prints for platinotype by unscrupulous photographers has been engaging our attention for some time past, and we are obtaining counsel's opinion as to the best means of putting an end to this fraud.

May we point out that you are mistaken in assuming that there are other makers of "Platinotype" papers besides ourselves, for such is not the case, as nobody but ourselves can use the term "Platinotype" for their manufactures.—We are, gentlemen, yours faithfully,

THE PLATINOTYPE CO.

22, Bloomsbury Street, New Oxford Street,
London, W.C.,

March 18th, 1904.

[We regret our inadvertent use of the term "Platinotype," which, we are aware, applies exclusively to the production of the Platinotype Company. There are, of course, other makers of platinum paper.—Eds., B. J. P.]

TRICHROMATIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—I was very much interested indeed to read in your last issue Mr. E. J. Wall's valuable contribution on p. 228. Mr. Wall's translations from the German are always helpful to us dabblers in trichromatic work, whose misfortune it is not to be able to read the works of Dr. Eder and others. Why, I would like to ask, has two years been allowed to elapse before we English readers could get a translation of this article? No wonder we are a little behind in three-colour matters. I'll bet my boots our English articles on the subject are translated into German before two years have gone.

—Yours, etc.,

A. H. WHITE.

Stoke Newington Road, London, N.

March 19th, 1904.

INTERNAL REFLECTIONS IN THE CAMERA.

To the Editors.

Gentlemen,—Since Mr. Welborne Piper asks for some practical details as to the use of orange paper in the interior of cameras, I am happy to forward a few particulars. Having often had occasion to use the medium in question, in various kinds of temporary apparatus devised for scientific and experimental purposes, I have nothing

but praise for its behaviour as a cure for reflection. In the case of slow plates it is invariably satisfactory, and much to be preferred to a shiny or bad black. With rapid plates, however, it has not proved so suitable; at any rate, with long exposures. A good, dull black is to be preferred in all cases, although such a black is, unfortunately, not too common.

I fear we must agree to differ about the lens hood. A rectangular hood might possibly be better for a rectangular plate, if it were not for the disturbing factor of the lens being circular. The consequence is that the difficulty of accurately adjusting a rectangular hood is considerable, so that it shall not cut off certain necessary portions of the illumination. Then again, the plate is not square, but oblong; so that unless the hood is made square, thus admitting unnecessary light at the four corners, it will be requisite to shift it whenever it is desired to alter the plate from an upright to an horizontal position. A circular hood avoids this difficulty, admitting the maximum of needed light and the minimum of surplus illumination.—I am, gentlemen, yours very truly,

A. LOCKETT.

88, Brook Street, Kennington, S.E.,

March 18th, 1904.

YELLOW STAINS ON PLATES.

To the Editors.

Gentlemen,—There is a strange yellow stain, said (I think recently in the "Journal") to be ineradicable, that sometimes occurs in the fixing bath. Its position is wholly in the clear portions of the negative, disappearing entirely in the half-tones. Its colour varies, in different negatives, from very pale yellow to very deep orange. It is said to be a deposit of silver in some form, and experiments so far bear this out. Bleached with mercuria chloride and re-blackened, the stain becomes a grey deposit.

This stain occurs in several ways. One of the best known, with plates, is the use of an exhausted fixing bath. An old bath, *per se*, is no cause. But the stain, once visible, cannot be fixed out. The strongest and freshest hypo has no power upon it. The same kind of staining seems to occur frequently with films. The fixing of many films without special apparatus is somewhat of a trouble. Unless kept moving in the fixing bath they will stain where lying on one another.

The most brilliant staining I have come across arose in this wise. Four whole plates were developed in turn, each when developed placed in a bath of water which had originally been used for rinsing plates on leaving hypo tank. On placing the last of the four in the hypo-contaminated water the stain was noticed, and all four were immediately placed in fixing bath. The last one was, of course, quite clear, but the other three were respectively more and more coloured (in the transparent parts only) up to a deep orange.

A cure was suggested in the use of a Howard-Farmer reducer after it had turned green. Experiments with this showed that the stain was removed, if the bath was not too old, also that there was no apparent reduction in the negative. After removal of the stain, a plate was left partially immersed for two hours without apparent alteration, and after thirteen hours was simply toned to a brownish black. Suspecting the removal of the stain to be due to the solution being still a reducer, but in a weak condition, a fresh bath was made up of:—

Hypo.....	1 oz.
Water	20 oz.
1 per cent. Potass. Ferridcyanide.	A few drops.

Another plate was evenly exposed, and developed to a slight veil only, a slip of this being placed in the solution alongside a yellow-stained plate. The stain was removed after a few minutes, the plates apparently being unredduced; but the test strip showed that a very slight reduction had taken place. This reduction is, however, of such slight moment that it may be neglected in practical working.—I am, yours, etc.,

Johannesburg, S. Africa.

C. HAROLD SMITH.

THE DECIMAL AND METRIC SYSTEM.

To the Editors.

Gentlemen,—The discussion between Messrs. Gotz and Piper on this subject has, at any rate on the latter's part, become mere hair-splitting, and waste of ink and paper.

Here is an example. Mr. Piper states that a litre of water weighs 997.8066 grammes instead of 1,000, the error is therefore 2.1934

grammes, or, as Mr. Piper prefers the duodecimal and English weights 33 ¹/₁₀₀₀₀₀ in. grammes.

As photographers, we are not accustomed to make up our solutions except hypo in litre lots, but smaller quantities. Will Mr. Piper kindly tell us what the percentage of error, or the error per ounce, taking into consideration, as he ought to, barometric pressure, reduced to sea level, for, say, Blackheath, at 15 deg. centigrade, instead of making up a 10 per cent. solution of chloride of gold in the ounce I prefer to use the metric system?

When he has worked this out, duodecimally and by grains, will he condescend to tell us what effect the error found will have if tone ten sheets of paper, 24 by 17½ in. each, with 200 cc., or l'Anglaise and à la Piper, 3,079 7-10ths fluid grains, or 7 39-1000ths fluid ounces, or 7 ozs. 18 8-10ths minims, or 3,378 8-10ths minims?

Can Mr. Piper measure out 7 ozs. 18 8-10ths minims accurately, and, if not, what is the probable error in 35 ozs. 94 1-10th minims, and what will be the final result on every quarter-plate print cut from the above-sized sheet of paper toned in his erroneously-measured gold bath?

I do not know either Mr. Gotz or Mr. Piper, but obviously the latter is not a chemist, nor accustomed, as I am, to make three or four analyses of waters and their solutions every day of his life, otherwise he would not talk as he does.—Yours faithfully,

AN OLD CHEMIST.

March 21st, 1904.

P.S.—I am a brewers' chemist, will you allow me to discuss with Mr. Piper the question of the arbitrary abolition of licenses by magistrates? If not, why not?

To the Editors.

Gentlemen,—I am unable to determine whether Messrs. Gotz and Tennant cannot or will not understand my reference to our duodecimal system. Both persist in running their heads against duodecimal notation, which, as I have already explained, forms no part of the system. The notation is decimal, and the introduction of any other notation upsets its use altogether. Though Mr. Tennant says, "even if a duodecimal system were demonstrably preferable; in fact, nowhere exists, certainly not in the British Islands"; still, this duodecimal system not only exists, but is in constant use by architects, surveyors, builders, timber merchants, shippers, and many others. Mr. Tennant's irrelevant tale of a table may be referred to to point out that while it is perfectly easy to measure the height of the table by any scale of dimensions you please, the area of the table-top or the cubic quantity of wood in the table can be more quickly arrived at by duodecimals than by decimals. As this kind of work is not paid for by time, it is obvious that speed is of the greatest importance.

Mr. Gotz's remarks as to replacing the decimal system by the duodecimal system, and as to using duodecimals as a "fundamental principle out of which a harmonious system of weights and measures can be evolved," simply show that he has not yet grasped what duodecimals really mean in English measures. Their use is only a time saving device, and I have at no time suggested that they could form the basis of a complete system of measures. The point is, that if the foot and inch be abolished, then the quick method goes too, so that the man who has mastered it loses both time and money.

Mr. Tennant is much more reasonable than Mr. Gotz in regard to the use of fractions. The latter gentleman said: "I can prove that for all purposes it requires less figures to write a quantity in decimal figures than in vulgar fractions, and that calculations such as multiplication and division are infinitely shorter and simpler." Naturally, he has not proved it, and it is interesting to note that Mr. A. J. Martin, who is an even greater metrical enthusiast than Mr. Gotz, states: "Decimalists do not uphold the exclusive use of decimal fractions, but employ vulgar fractions if they see that under certain circumstances these would be quicker or more accurate; in fact, neither decimal or vulgar fractions are best under all circumstances." Thirds, sixths, and sevenths may be an abomination to Mr. Gotz, but he cannot get away from them. Presumably, the angle of an equilateral triangle ought not to be two-thirds of a right angle, but it is; hence the decimalisation of the circle has proved a failure, and for very similar reasons other undesirable fractions persist in appearing, however much they may annoy Mr. Gotz. I sup-

the use of $.7\frac{1}{2}$ instead of $.725$ would illustrate what Mr. Gotz is a "half-hearted" use of decimals, but he must surely be aware that this is one of the devices employed by decimalists whenever able. Unfortunately, with a decimal system of measures or weights this short method is so seldom available, whereas non-decimal systems afford numberless short cuts. Nothing shows this more clearly than our monetary system, which even such an ardent decimalist as Mr. Sonnenschein declares "is the best in existence, should be copied in toto by all the other nations." It is curious that he should be of this opinion, considering that his own method is not by any means as short as those usually adopted by Englishmen.

With reference to the metrical problem I submitted, it is remarkable that neither of your correspondents suggest the use of the avoirdupois and fluid ounce for making up the solution, though their use is clearly indicated. It is even more striking that neither of them refers to the conventional litre containing 1,000 gs. of water at a temperature of 15.5°C. , or 60°F. , which is commonly used for similar purposes. A litre graduated at a normal temperature is obviously desirable that the inconvenient standard metric units have been supplemented by the conventional litre, which fact was not mentioned at all in Mr. Gotz's paper.

The figures 997.8066 given in my last letter are incorrect owing to my use of tables that gave approximate values without indicating fact. The true figures, as near as I can get them are 997.7904, and Mr. Gotz will no doubt at once recognise as representing the weight in grammes of a standard litre of water at a normal temperature of 62°F. , according to the Board of Trade equivalents. It appears that the standard litre at 62°F. is about two grammes less than its theoretical weight, while, according to Professor Mendel's cubic decimetre at the same temperature is about one gramme less weight. Hence, the cubic decimetre is larger than the standard litre at equal temperatures, though smaller than the conventional litre graduated at 60°F. Neither of your correspondents can be aware of the confusion that has arisen through these complications, or of the mistakes that have been made through blindly trusting the theoretical arrangement described by Mr. Gotz. If the metric system is to be used intelligently it is certainly necessary to emphasise the fact that the litre and cubic decimetre, or the millilitre and cubic centimetre are not simple interchangeable measures of capacity.

With your correspondents kindly assume that I am discussing a matter of measurement that I am not practically acquainted with. On the contrary, I use the metric system myself whenever circumstances indicate that it will be most suitable, but practical experience of the art of measurement, which plays a great part in my profession, has forced me to recognise that it is not by any means so simple as it is often represented to be. The metric system is at its best for scientific work, but at its worst for ordinary every-day work in the real world. A unit such as the millimetre, which is much too small to be a "fine" dimension, and too small to be subdivided without a micrometer, is utterly useless for much of my work; hence, like many people, I discard it in favour of the decimally divided inch, which I can read down to the hundredth part with perfect accuracy and without any optical or mechanical assistance. Further, I am well acquainted with the numerous short methods used by decimalists, and use them pretty frequently, but then I also know that English business men employ very much shorter methods when dealing with English coinage and measures, and generally avoid decimals as productive of a waste of time and figures. For example, it is easier to find $3\frac{1}{2}$ per cent. on £67 than $3\frac{1}{2}$ per cent. on 67 dollars and cents, owing to the fact that the decimal coinage necessitates multiplication by two figures and the use of two or three working figures, whereas with the £67 there is only one multiplier and not a working figure is required by even the slowest witted youth. A glance at the sum shows the answer in pounds, shillings, and decimal parts of a penny. The inconvenience is due solely to the decimal division of the coinage, and, however you abbreviate the working, there is nearly always a shorter method available for non-decimal money than with any decimal coinage in use. It does not apply so fully to measures, where I admit a decimal can be to be often convenient, but it applies with sufficient frequency to show that a purely decimal system of measures is defective in principle and not conducive to efficiency. The metric system, in

particular, is unsuitable to our general requirements, because, while it is purely decimal throughout, it cannot be used in unison with any part of ours. We want a decimal system, but not one that contains no single unit in any way comparable with one of our existing units. If the metre agreed with the yard the whole matter would be on a different footing; we could retain such of our present units as have a distinct value, and at the same time reduce from one system to the other with perfect ease. Such a system as that would be adopted at once without hesitation, but to adopt a system that is well recognised as imperfect, and cannot in any way be reconciled with either existing systems or records, is only to add to the present confusion; for it must be remembered that no Act of Parliament can abolish and obliterate the present measures, which will remain in use probably for centuries. Other countries have failed to get rid of their old measures, though such a change can be far more easily carried out in any country rather than this one.

A point often neglected is the fact that our trade with metrical countries is small and unimportant compared with our trade with non-metrical people. It appears that only about two-fifths of our overseas trade is with the former, and that is steadily diminishing, while the other three-fifths is with non-metrical countries, and is steadily increasing. The adoption of the metric system would thus inconvenience our best customers, and our home trade, while it would undoubtedly be a greater benefit to our metrical rivals than to us. At present we hold the whip-hand, for our measures trouble our metrical rivals much more than they do us or our non-metrical friends, and, of the two alternatives, it would pay us far better, and be much easier, to introduce a new system suitable to our requirements than to adopt one that we know to be inconvenient. Interested parties are very anxious that we should adopt the metric system as it stands, for the very simple reason that they would then be able at once to compete with us in our own markets with greater profit than they can at present. Think of the certain result of our adjusting all photographic apparatus to metrical gauges. We should immediately be flooded with Continental plates and cameras, and a severe competition would very soon be supplemented by the gentle agency of "dumping." Other trades are considering this point very carefully, and photographic manufacturers would do well to follow suit; possibly they have as yet hardly realised the extent to which they are "protected" by the fact that we do not use plates of Continental sizes.—Yours, etc.,
C. WELBORNE PIPER.

March 22nd, 1904.

"THE PHOTO-TICKER," published by Mr. W. P. Buchanan, of Philadelphia, thus advertises the introduction of a new flash-powder:—The Greasy Dutchman is dead. We are happy to chronicle the end of trouble as far as "Prof. Schumann," alias "The Greasy Dutchman," is concerned. He dropped dead in Pittsburgh on April 27th, and the coroner notified us that his grave is No. 264. (It seems hardly the right way to publish an obituary notice—to say "we are happy to chronicle, etc.," but when an individual becomes a nuisance and a dangerous element he is better dead than alive. We forgive him, and if you are one of his many victims we hope you will do likewise. Poor fellow, he has no doubt gone where flash powder would be unsafe to handle—his troubles on earth are ended, and the world is better off. *Deo Gratias!*)

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

- * * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.
- * * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- I. Ratcliffe, 8, Wharf Street, Sowerby Bridge. Photograph of Rawdon Collinson.
- J. Jackson, Elder Bank, Blackley, Manchester. Photograph of Thirteen Original Members of the Rochdale Equitable Pioneers' Society.
- L. Anthony, 2, High Street, Kilarney. Photograph of Irishman in Donkey Car. Photograph of Irish Colleen on Donkey Car. Four Photographs of a Kerry Colleen.

JOHN TERRAS.—It might realise a few shillings if advertised.

BISCUITS.—The specimen sent shows that the medium used renders the paper very transparent and suitable for its purpose. We are pleased to learn we have been of assistance to you, and wish you success.

C. E. MANNALL.—Do you not mean Crystoleum Painting? Barnard's Complete Crystoleum Outfit for the process, and full instructions can be obtained from Jonathan Fallowfield, 146, Charing Cross Road, London, W.

E. G. HARCOURT TYRRELL (Pietermaritzburg, S.A.).—If you address Mr. Ives, care of the Franklin Institute, Philadelphia, you will no doubt obtain the information of which you are in need. We cannot possibly answer letters by post.

SINOP COLLOTYPE PLATES.—F. RUTTINGER writes: "In the volume for 1902, page 893, the 'Sinop' Collotype plates are reviewed. I should be much obliged if you would tell me where they may be bought?" In reply: Address, Messrs. Penrose and Co., Farringdon Road, London, E.C.

PATENT INFORMATION.—CONRAD asks: "Will you inform me of the best means of acquiring a knowledge of the rules relating to patents, so that I should know how to proceed in the event of my wishing to take out a patent?" In reply: You may obtain a form at any post office, price eightpence, which will probably meet your requirements.

C. L. HARTE asks: "Could you kindly tell me a recipe for renovating the leather covering of my camera, which has got rather shabby?" In reply: Either the "Bertha" Leather Reviver, sold by the Vanguard Manufacturing Co., Maidenhead, or Tylar's Leathesvas Finish, both of which are obtainable in 6d. and 1s. bottles at most photographic dealers, will do what you require.

A. W. EMARY.—The technique of the work submitted is chiefly open to criticism by reason of the occasional harshness of the lighting. Otherwise it is very good, and should entitle you to a salary of from £2 to £3 a week. A study of the portrait work at the principal London exhibitions would no doubt suggest directions in which the work is capable of improvement.

CARBON TISSUE.—C. M. says: "I shall be greatly indebted to you if you can instruct me how to destroy the latent image in carbon tissue. Is it possible to undo the work done by light action on gelatine sensitised in bi-chromate of potash without destroying the gelatine? That is to say, can it be used again like fresh tissue?" In reply: There is no practical method of doing this. If there were, the thing would not be worth the trouble.

UNINFLAMMABLE CALICO.—"Uninflamable" asks: Could you, please, inform me, where I could buy uninflamable calico, and if not sold commercially, how could I prepare same?" In reply:

So far as we are aware, there is no such thing as uninflamable calico on the market. Ordinary calico, however, is rendered uninflamable by simply immersing it in a solution of tungstate of soda and then drying it. In place of tungstate of soda, common alum may be employed, but the tungstate is the better.

JESS MITCHELL asks: "How can I obtain a sepia tone on P.O.P." In reply: There are many excellent formulæ for obtaining sepia tones on various brands of P.O.P. given in the "B. Almanac" every year. We can, however, recommend the following:—

A.—Potassium chloro-platinite, 15 grains in 15 ounces water, to which have been previously added 5 minims of hydrochloric acid.

B.—Citric acid, 160 grains; Chloride sodium (common salt), 160 grains; Water, 8 ounces.

Take 2 ozs. from A and 1 oz. from B, and make up to pints with water. This is sufficient for toning about 30 plate prints. Matt surface paper looks best toned in bath.

COLOURING—RETOUCHING.—READER says: "I should be very pleased if you could answer me the following questions:—First, a tinting photos with water colours on a polished surface, paint shows very dull if you hold it sideways. Can you use any varnish or medium that would take off the dullness? I have tried burnishing them, but have not found it to answer. Second, will you kindly inform me what is the real meaning of 'clever with the knife?' I often see this in the vacuum column where a retoucher is required. Of course, I can move any part of a negative that is not required by scraping etc." In reply: 1. The only thing we can suggest is that you use more gum with the colours; they will dry with more gloss. 2. By clever with the knife is meant cleverness in removing certain portions in a negative, when it is required to do so without the work showing in the print.

PHOTO RELIEFS.—H. DU F. (Johannesburg).—Where could I find the instructions and formulæ for producing negatives in high relief suitable for making plaster moulds, etc. In reply: A book dealing with the Woodbury-type process, such as Burton's "Photographic and Photo Mechanical Process," will tell you how to make gelatine reliefs. But for plaster moulds, if high relief is required, the "swelled gelatine" process will be better than the Woodbury one. Apply a thick coating of swollen gelatine to a glass plate, and allow to set and dry. Then immerse in a 5 per cent. solution of bichromate of potash until the film is thoroughly permeated. This will take some minutes. Dry, and then expose behind a strong negative. Put into cold water, when the portions not acted upon by light will swell up in high relief. In place of coating the glass with plain gelatine, the bichromate may be added to it if you have means of quickly drying it.

WRONG CREDIT GIVEN.—PHOTOGRAPHER says: "I wish to have your advice on the following difficulty:—Some time back, during 1903, a traveller of a well-known firm in England called on my studio and invited me to supply him with some views of London to reproduce in an album which his firm was about to publish. I declined to do so on the ground that I had already placed my order with another firm for the publication of an album with views of this town photographed by myself. I therefore desisted from his demand, and bought one only view of a certain place. Soon after, the publication of his firm's album took place. I was surprised to see among the collection that very view reproduced bearing another photographer's name. It so happens that the view in question taken by me surpassed in detail any one taken by other competitors, and the publishing firm have acknowledged this fact by reproducing my view, failing, however, to put my name to it. Will you please advise me what action should I take against the firm for having put another photographer's name to a view taken by me? I may add that my view is not registered." In reply: The matter is certainly very annoying to you, and not at all creditable to the firm in question. We are afraid, however, that you have no remedy, particularly as the copyright in the picture was not registered.

EX CATHEDRA.

Photographic Survey for Kent. We are asked to announce that the Committee of the South-Eastern Union of Scientific Societies is anxious for the formation of a Photographic Record and Survey Association for the County of Kent. Surrey already has such an association, which has just completed a most successful first year's work, and it is hoped that the organisation in Sussex may follow that of Kent. The Kentish survey will probably form its principal deposits of records in a county museum at Maidstone, and will also contribute to the collection of the National Photographic Record Association in the British Museum. A meeting of persons interested in the proposal, and of delegates from photographic, archaeological, and other societies, is to be held in Maidstone on April 16th, for the purpose of forming a provisional committee to draw up rules and to submit a working scheme to the Congress of the S.E. Union, which will meet in Maidstone on June 9th, 10th, and 11th. The exhibition in connection with the Congress will have a section devoted to photographic record and survey work. Societies and individuals interested in the movement are asked to communicate with Mr. H. Snowden Parnell, Hadlow, Kent, who has undertaken the preliminary organisation.

Abuses of Public Advertising. In the JOURNAL last week we published a letter from the hon. sec. of the society formed for attempting to place some restrictions on the glaring advertisements that at the present time disfigure alike both town and country.

If this body proves successful in their efforts, no persons should be more thankful to them than photographers. It is quite true that, at the present time, the hoardings let for advertising purposes are quite different from what they were, even a decade ago. Many of the posters now seen have quite pictorial merit, and some hoardings may almost be classed as al-fresco picture galleries. But photographers do not always look upon them as such, particularly when they have to depict a street scene, or, may be, some public building, and have necessarily to include some, in this case hideous, advertisements in their pictures, as there is no possibility of avoiding them. Again in the country a landscape that would form an excellent picture is marred by some obnoxious advertisement of somebody's pills or other quack nostrum. It must be included in the picture, or the picture foregone. Painters are here in a better position than photographers. They can paint their picture with all the beauty of the landscape, and leave out the obnoxious advertisement; whereas the photographer has, perforce, to include it in all its obtrusiveness. Still this is an utilitarian age, and so long as there is no law to prevent it, one can scarcely blame anyone who has space, and the opportunity, for turning it to profitable account for advertising, or any other purpose, without considering the subject from an æsthetic point of view.

Shutter Speeds and Shutters.

Every hand camera of the present day is provided with an "instantaneous" shutter of some kind or other with an index marked in fractions of a second. Pictures taken with them are shown with the stated speed of the index inscribed upon them, but how many of the producers have verified the index to prove whether it is correct or not? If they were to do so they would, in very many cases, find that the speeds marked were very much at variance with the actual speeds at which they work, particularly with those on the cheaper forms of cameras. We happen to have in our possession some half-a-dozen shutters of different forms, with indexes, and when they are all set at, say, 1-10 second, there is a wide difference in their speeds, as can be seen by the eye. If this discrepancy is so palpable with the slow speeds, one may well surmise that it exists also in the higher ones. Again, if the speeds marked on the indexes were correct when the shutters were issued by the makers, how long would they remain so under the conditions which they are subjected to? For example, it is no uncommon thing for a shutter, we will say, depending upon a spiral spring for its action, to be used at its highest speed, and for the apparatus to be nut away, possibly, with the full tension of the spring on for weeks. It is easy to see that this continued tension has a tendency to weaken the spring and render the shutter slower in action when next used. Again, those

shutters that depend upon pneumatic action as governing the exposure, if a small particle of grit, which, on a windy day is impossible to avoid, gets in the cylinder the action is at once slowed by the friction produced. But what matters it, in practice, whether the speed marked on the index is correct or not so long as it is constant when set at any of the speeds on the indicator, whatever they may be? The user knows that when the shutter is set at any particular speed he gets a certain exposure, and it is of little concern to him whether it be the fifteenth or the twenty-fifth of a second in actual time, so long as he gets the result he wants. In our own practice, and with the view of having our shutters as constant as possible, we make it a practice to always release the spring and let it run down after the day's work is done. This tends to keep the spring of whatever form it may be in practically an uniform condition.

Miniature Painting and Photographic Miniatures.

In "Ex Cathedra" last week reference was made to the miniature painting of a generation or two ago, and the probability of its being revived in the near future. During the past week the art world has been greatly interested in the auction sale, at Christie's, of one of the most remarkable collections of miniatures and snuff-boxes that has probably been held, and the prices realised for some of the works. Four days' sale realised no less than £54,000. This unique collection was got together by the late Mr. C. H. T. Hawkins, and forms but a portion of the works that have since come under the hammer of the auctioneers. It may be explained to those who may not be aware of the fact that many of the snuff-boxes are embellished with fine miniature paintings in enamel, and are works of art in themselves. On box alone, so embellished, fetched the sum of £1,550. Some of the miniatures brought almost fabulous prices. For example, one of "A Lady," by Englehart, made £435; another "A Lady," by Cosway in 1788, fetched £340; and a Louis XVI. gold tablet case, with panels of purple transparent enamel, and miniatures of Louis XVI. and Marie Antoinette, were knocked down for no less than £510. One small panel picture, "The Guitar Player Surprised," measuring $13\frac{1}{2} \times 10\frac{1}{2}$, by Watteau, realised the sum of 2,400 guineas. As we mentioned, last week, there is at present a tendency towards the revival of miniature painting, and some of the leading photographers are fully aware of the fact, and are making a feature of it in their business. But it must not be surmised that a coloured miniature on a photographic base, however skilfully done, will ever equal the work of such men as Cosway and others of the old school. The surface of a platinum print is excellent for colouring upon, but the old miniatures were upon ivory, which is undoubtedly the best material for the artist to colour upon. Photographs on ivory are produced by the carbon process, but here the painter has not as of old, the bare surface to work upon, but one of insoluble gelatine. The pictures are made by the double transfer method, and the ivory has to be prepared with a substratum of gelatine in order to secure the image to it, and the picture itself is gelatine. Hence the conditions are different from what they are when the artist has the bare surface of the ivory to begin upon. A large number of the works sold at the Hawkins sale were enamels, and photographers would do well to give attention to coloured miniatures on enamel. Photo-enamels are very beautiful in monochrome, but they would be still more beautiful if they were skilfully coloured, and we have seen some that, although they could not compare with the work of Essex and others, were very good. Really good coloured photo-enamels can never be done at a cheap rate, and so they

are never likely to become common. They must always be confined to the wealthy alone. This will be understood when it is explained to those who are not aware of the fact that every colour—or nearly every colour—has to be fired in separately. The most refractory colours have to be fired in first, then follow the next refractory ones, and so on, a dozen or more firings being sometimes necessary.

DIAGRAM LANTERN SLIDES.

THOSE familiar with lantern exhibitions know how often a good lecture is marred by poor diagrams—defective by reason either of imperfect copying or good copying of an imperfect original. We do not refer, of course, to diagrams built up during the progress of the lecture, and shown on the screen after the fashion of a drawing of a plan done on the blackboard in front of the audience, the method being, as we need scarcely remind our readers, easily carried out by a special arrangement of the lantern, the drawing being made on a horizontally placed surface such as perhaps is best made by the smoke of burning camphor received upon a glass surface slightly paraffined over by warming, rubbing with the end of a paraffin candle, and then almost wiping it off again. The slides we speak of are those photographed from plans or sketches specially drawn or selected for the lecture, and from which negatives have been made. Naturally, the roughness and want of pluck in such slides is not always the fault of the photographer. If a poor drawing or plan is brought to him, nothing but a poor slide can, as a rule, be made from it; but instances too often occur where a little skill and thought brought to bear will enable excellent results to be obtained from unpromising materials. For example, a newspaper cutting, possibly crumpled, brought to be copied. If pinned up in the studio and straightened out as much as possible, a dirty looking slide, with the crease marks and the grain of the paper plainly visible, and the printing at the back showing through, will be the result. Let, however, the cutting be pasted upon a piece of wetted paper, and the whole, while damp, strained on a smooth piece of board by pasting the edges and all the marks will disappear when dry. The grain will be lost by illuminating the print from both sides, which can be done by the aid of a mirror if a front light is impossible. The printing at the back will still show through, but will be entirely eliminated if the precaution be taken of pasting the cutting on black instead of white paper, and, if the cutting is valuable, and may not be tampered with, almost equally good results may be obtained, as far as eliminating the effect of the back printing is concerned, by placing the cutting in a printing frame, and backing it dry with black paper.

A difficult class of subject to photograph without loss of time is a diagram in a book, as it cannot be removed without injuring the work. The best procedure is to lay the book on a board, open it at the required place, tip the diagram or picture is quite vertical, then, placing a sheet of glass—preferably plate glass—against it, and, if possible, tied with two pieces of twine at top and bottom to ensure flatness, to keep the print vertical by some easily-devised temporary expedient, such, for example, as a number of books piled up. There then remains only further precaution to take; the open page of the book that lies horizontally in front of the print, must be covered over with a piece of black velvet, or even dead black paper. If this be not done, a foggy negative will be obtained, owing to the open page being reflected from the plate glass and superposed upon the image proper. Some lecturers prefer diagrams in white upon a black ground. These, of course, are simply made by supplying

the negatives itself without the medium of a transparency. The objection to such slides is that the lecturer cannot use a pointer to explain his diagrams. A much more elegant plan is to keep the negative on the thin side and convert it into a blue or green by a well-known process. Such slides are so far not common; if introduced, they will be much admired, and a slight extra charge would be willingly paid.

Returning now to the ordinary clear slide with black lines it will be advantageous to make the transparency unnecessarily dense, and then clear the whites by the Howard-Farmer reducer. It is astonishing what a great help this is to the obtaining of absolutely clear whites. Nothing looks worse on the sheet than a good diagram showing on a dirty, or patchy, white ground. A dense negative is essential for obtaining direct the best results, and to this end it is far better to obtain density by intensifying with mercury rather than by protracted development, which tends to fog the faint lines. Our recent remarks upon pinholes may be read in this connection, mercurial intensification having a tendency to induce this defect.

At a recent meeting of the Physical Society, Dr. W. Watson gave some "Hints on the Preparation of Diagrams" that will be found useful to those of our readers who take up this class of work. He stated that many of the diagrams and curves accompanying papers submitted to scientific societies have to be re-drawn on Bristol board before they are suitable to be photographed, and he pointed out the usefulness of drawing these on blue-line section paper. By slightly over-exposing the plate the lines, he said, were quite invisible on the negative. One non-photographic hint he gave is well worth recording. The difficulty of, and the time lost over, lettering diagrams is well known, and he recommends the use of indiarubber-faced type, using Binfield's Persian black with glycerine as the ink. He referred to the usefulness of the larger size of type of the well-known "Easy Sign-makers," which are also supplied with rods to ensure alignment and circular arcs for arranging the lettering in a circle. The suggestion is most valuable, for the time involved in lettering a diagram, or printing a description upon it, can only be known by those who do such work.

We have by no means exhausted the possibilities, photographic and non-photographic, of diagram making for lantern slides, and we may possibly return to the subject on some future occasion.

BEYOND OUR GRASP.

THERE are very few things in the world which cannot be photographed, and the word "world" must be taken to include the recesses of the deepest mine as well as the attenuated atmosphere far above the sea-level, which is only known to the most daring of balloonists, and in a modified degree to mountain climbers. As for the more properly terrestrial things the camera pokes its nose, or rather its lens, into all the affairs of men, and whereas a few years ago it might be regarded by many only in the light of a fashionable toy, it now is to be found in every laboratory, ready on the instant to record things which are so rapid in their happening that no human eye is capable of detecting their movements.

Atmospheric phenomena of various kinds have been photographed, and the modern study of meteorology is doubtless much helped by the beautiful pictures of cloud-land which have been produced. They are necessarily beautiful, but their handsome looks do not recommend them to the man of science as much as the evidence they

afford of direction of air currents, of altitude (when simultaneous pictures are taken from two separated stations for after comparison), and the opportunity they give of making a more reliable classification of appearances which are so ephemeral, that at the best they form a most difficult subject of study. Photographs of lightning are always attractive, and it is known to meteorologists that such pictures show peculiarities of form which were never seen before the camera was used as recorder. As to pictures of star-land, the photographic dry plate has, by the wonderful things it has achieved, caused quite a revolution in astronomy. One of the foremost workers in this splendid field of scientific work has stated his opinion that the wedding of the telescope with the photographic dry plate has helped astronomy as much as did the discovery of the telescope itself. Stars so inconceivably distant that no eye has ever seen them, even with the help of the most powerful instruments, have, by the cumulative action of their lights exerted over a period of some hours, recorded their presence on the dry plate, and it has been calculated that by the help of photography a map of the universe would be possible, showing about 160 millions of orbs. A map, indeed, is now in progress, but by common consent among the observatories of the world, each of which will contribute to it, the mighty chart is to contain only two million of the brighter stars of the firmament.

It would seem, then, that the title of this article is a misnomer, and that there can be nothing beyond the grasp of the ubiquitous camera. There is no rule without its exception, and the exception in this case seems to be that beautiful appearance in the heavens known as the Aurora Borealis, or Australis, according to whether it is seen from the Northern or Southern Polar regions of the earth. As far as we can gather, this beautiful thing has never been photographed, and we may regard it as an apparition which, with our present appliances, cannot be pictured by the camera.

The Aurora Borealis is very seldom seen in a latitude as low as that of London, and we can recall but two instances in which it was bright enough to excite general remark. The first was as long ago as October, 1870, when the sky seemed to be lighted up in patches of rosy light not only in the North, but all round the horizon. That the light given was pretty bright may be judged from the circumstance that the fire-engines turned out from various districts. But it should be mentioned that possibly the electric alarms may have been caused to ring up the firemen by the automatic acting of the apparatus owing to the disturbance set up by the Aurora itself. It is placed on record that in 1859, on two different dates, brilliant Aurora Borealis acted so powerfully on the electric telegraph in France and other countries, that for a time communication was altogether stopped. It will be remembered, too, that only a short time back induced currents from a magnetic storm played havoc with telegraphic messages over the greater part of Europe.

The other instance of an Aurora seen in the Metropolitan district occurred about five years ago, and we happened to observe it under exceptionally favourable circumstances from a boat on the upper Thames. This Aurora was not quite unexpected, for some big sunspots had been seen, and it is not uncommon for Auroral phenomena to accompany such appearances. In this case it came, first as ghostly columns of white light in various parts of the sky, and soon afterwards as a fan of rays in the North, through which the horses and wheels of King Charles's wain could be plainly seen, as through a diaphanous veil. Although in this case, the light was, as we have said, perfectly white, and although the rays

were strong enough to attract the attention of everybody, they were, we felt convinced, too faint for any record on a photographic plate, and they did not keep still. At one moment one of the rays would elongate, at another it would shrink, and attention was diverted from it to one of its fellows which, for the time, attained great prominence.

But if anyone wished to see Auroræ at their best, he must betake himself to either the Arctic or Antarctic regions. Probably one extremity of the earth would be as good for this purpose as the other, but the quest of the North Pole has been such a constant story of endeavour since the childhood of most of us, that the Northern Aurora has been more generally spoken of in our hearing, and it seems to be more within our reach than the Southern one. The Aurora Borealis is generally pictured as a series of vertical curtains, with folds in them just like the crinkled paper of which table-lamp shades are made, and the most extravagant language has been employed to describe their brilliant colouring. But they have never been photographed, so far as we can learn, although many attempts have been made to picture them by the camera.

There is no doubt at all that there has been a good deal of exaggeration concerning the amount of light given out by the Aurora, even when seen at its best. We have before us, as we write, a very interesting book by Sophus Tromholt, "Under the Rays of the Aurora Borealis" (1885), which gives a full account of the land of the Lapps, and which touches in a brief manner on this matter of photographing "the Northern lights." The author says that the idea that this light in any way compensates for sunlight is a mere fable, and that it assists travellers in their journeyings is a gross exaggeration. It must be of unusual brilliancy to be seen at all when the moon is full, and the sky clear. Sometimes the Aurora will give flashes of extra brightness, but these are so brief that "the light emitted is of no practical value whatever to the inhabitants of the polar regions." The author further intimates that the Aurora at its best does not give a light equal to the full moon, and that on rare occasions he could read by its aid type about $\frac{1}{2}$ in. high.

But the most interesting part of his account of the Aurora is his story of the attempts which he made to photograph it, which we will give in his own words:—"Every attempt I made to photograph the Aurora Borealis failed. The result was the same at the stations at Bossekop and Sodankylä. In spite of using the most sensitive dry plates, and exposing them from four to seven minutes, I did not succeed in obtaining even the very faintest trace of an image. The reason is, I am convinced, the small strength of light, and its limited chemical action."

Mr. Tromholt devotes a great many pages to a description of the Aurora, and he speaks of masses of luminous matter suddenly appearing in the sky, wave-like motion, wave-like flaming, quick motion—all his expressions giving an idea of something in constant movement. And we are therefore led to believe from this description and also from what we have ourselves witnessed in a modified degree in this country, that the difficulty of photographings is caused by the unrest of the Aurora rather than by its want of brightness. If the Aurora would "keep still" as well as "look pleasant," to use the old studio formula, it could be photographed, provided the camera were connected with an astronomical clock movement so as to counteract the movement of the earth, and provided that a sufficient exposure were given. For we may surely assume that if invisible stars can be photographed, a thing which covers a far greater area and which gives

enough light for the reading of type, should also be photographable.

The light is comparable with that given by a Geissler tube through which an electric current is being projected by a coil, and such a tube we have been able to photograph by its own light in a room otherwise dark, by means of a few minutes' exposure of a rapid plate, and although the tube, by reason of its proximity to the camera, gives a much greater light than the Aurora, we may look upon both as being of the same kind of luminosity, we may, indeed, regard the interior an exhausted Geissler tube as being in the same state as the region above the atmosphere of the earth where the Auroræ are believed to occur.

It is a matter of interest just now to turn to Sir W. Ramsay's recent explanation of the Aurora Borealis. We have lately heard, in connection with the wonders of radium, so much about those hypothetical particles of electrified matter called electrons, that they are becoming quite familiar. Sir W. Ramsay believes that the sun is sending out swarms of these particles and that, acting on krypton, the recently-discovered element, in our atmosphere, they produce the Auroral light. This new view of the Aurora is endorsed by Dr. Johnstone Stoney, who, in a letter to "Nature," points out that this action of the outpour of particles from the sun on krypton produces the green Auroral line seen in the spectroscope. He further believes that this same outpour "presumably with equal, and perhaps increased, vigour, imparts energy to the molecules of helium, which range to still greater altitudes."

There is no reason to suppose that the most rapid plates now made are the most rapid possible. The difficulty of the plate maker is not in the increase of rapidity, but in finding a safe light to work by. It is quite possible that in the future mechanical means will be contrived for making emulsion and coating plates and films in absolute darkness. We already have appliances for changing and developing under like conditions. With such super-sensitive surfaces, a photographic image of the Aurora Borealis should not be impossible.

SOME SPECTROSCOPIC STUDIES ON TRICHROMATIC PHOTOGRAPHY.

III.

DR. EDER now commences his notes on light filters, and lays down at the commencement the important axiom "that it is by no means permissible to come to a conclusion as to the suitability of a colour filter, from the commencement or end of its absorption spectrum, or from its absorption minimum. For there are many dyes which are not sufficiently transparent and which even in the zone of the greatest transparency measurably dampen the light." As an example of this he quotes acid violet 4 B. (Bayer), which is a brilliant violet dye, similar to methyl violet, but much more stable to light, and with which an excellent violet filter may be prepared in a strength of 1:2,000, and which corresponds in colour absorption to a methyl violet solution of 1:10,000, but the acid violet filter requires a much longer exposure than the methyl violet one, and this is shown from Fig. 4. This is due to the acid violet damping the light, which cannot be visually detected, but which the more sensitive silver salts can prove.

The author uses his filters in liquid form and of 1 cm. thickness, and he lays stress on the fact that commercial dyes vary enormously, although bearing the same name, so he is careful to give makers and signalise the particular sorts as far as he can.

Not content with photo-spectroscopic tests of his filters, he

gives the luminosity and extinction-coefficient of his filters and various dyes for every ten wave-lengths throughout the spectrum, but as these are rather of more theoretical than practical interest they are omitted. There is, however, just a short abstract which is of interest; a methyl violet screen 1 : 10,000 when freshly prepared transmits from λ 694— λ 625 from 0.88—0.18 luminosity (1.0 being perfect transparency or full luminosity), after some weeks' exposure to light it shows in this region perfect transparency to these rays; again, the freshly-prepared solution gives from λ 618— λ 483 complete absorption, after exposure to light it transmits 0.13—0.03 light, and, whilst a freshly-prepared solution is absolutely transparent from λ 440, a stale solution shows a strong absorption band in the green from λ 597—517, its complete transparency does not commence till after λ 465. These few figures carry a powerful lesson to users of liquid filters.

Bromiodide collodion plates require no violet filter for the yellow printing plate, and for half-tone blocks the best formula is—

Cadmium iodide	7 g.
Ammonium iodide	3.2 g.
Ammonium bromide	1.2 g.
Alcohol	175 ccm.

Dissolve and filter

Add one volume of the above iodiser to three volumes of per cent. raw collodion, sensitise in a 10 per cent. silver solution, and develop with acetic sulphate of iron solution.

For the red printing plate the author used erythrosine plates, either bathed or commercial plates; the latter, he states, show a better gradation than the bathed plates; these plates require very strong correction filters, and their orange and yellow sensitiveness must be considerably dampened and the maximum action shifted to the bluegreen, which the author effects by the use of a filter of Janus green and auramine, the absorption of which is shown in Fig. 5, the upper curve being the sensitiveness of an erythrosine plate, and it will be seen that the maximum transparency of the filter coincides with the minimum of the sensitiveness.

Fig. 5.—The upper curve shows the sensitiveness of an erythrosine plate; the lower curves the absorption of Eder's Auramine and Janusgreen filter.

Janus green G is an azo dye prepared from diethylsaffranine and β -naphthylamine; the composition of the actual filter is—

Water	100 cc.
Janus green solution 1 : 1,000	10 cc.
Auramine solution 1 : 1,000	10 cc.

a 1 cm. thickness. Whilst perfectly efficient, this filter is not anywhere absolutely transparent, and therefore it prolongs exposure and further auramine in solution, both in the dark and light, deposits a yellow crystalline precipitate, and therefore the author prefers a filter of new patent blue and ammonium picrate.

Baron Hübl's filter of acid green and potassium bichromate is—

Acid green solution 1 : 10,000	10 cc.
Potassium bichromate solution 1 : 100	10 cc.
Water	25 cc.

Cell thickness 1 cm., is very bright, and for some purposes, where only a moderate damping with the yellow screen is required, it is satisfactory, but it is hardly sufficient for an erythrosine plate, and the suppression near F reaches too far into the blue-green. The characteristic absorption is shown in Fig. 6.

Fig. 6.—Hübl's acid green and bichromate filter absorption curve.

The best green filter for erythrosine plates is a mixture of ammonium picrate and new patent blue; this dye is Neu-patent blau 4 B, made by Bayer and Co., Elberfeld. Fig. 7 shows the absorption curves of three different concentrations of the blue dye, with approximately constant strength of the picrate. The best filter is—

Water	85 ccm.
Ammonium picrate solution 1 : 200	30 ccm.
New patent blue solution 1 : 1,000	15 ccm.

Fig. 7.—Curves of Eder's ammonium picrate and patent blue.

I. Shows the absorption of:—

Ammonium picrate 1 : 200	30 cc.
New patent blue 1 : 1000	15 cc.
Water	85 cc.

II. Shows the absorption of:—

Ammonium picrate 1 : 200	30 cc.
New patent blue 1 : 1000	10 cc.
Water	85 cc.

III. Shows the absorption of:—

Ammonium picrate 1 : 200	30 cc.
New patent blue 1 : 1000	5 cc.
Water	85 cc.

for erythrosine bath plates, whilst for many commercial plates, such as Lumière yellow and green sensitive, in which the maximum is not so near the yellow, the patent blue solution may be reduced to 10 cc., whilst for monobromofluorescine collodion plates it may be still further reduced to 5 cc., though frequently this is too strong, and excellent results are obtainable with a filter filled with plain water or with a little eosine dissolved.

The absorption curves of potassium bichromate, naphthol orange, and ammonium bichromate are shown in Figs. 8 and

Fig. 8.—Absorption curves of potassium bichromate.

I. Solution 1 : 100. II. Solution 1 : 1000.

9; that of auramine in Fig. 10. Tables of wave-length absorptions are given of the above, but are hardly worth reprinting. It is as well, however, to translate Dr Eder's comment on the bichromate filters: "One per cent. solution of potas-

sium bichromate dampens the blue and blue-green very strongly and with a tolerably steep curve (see No. 1, Fig. 8). More dilute solutions 1 : 1,000 give a gradually ascending absorption curve from the green to the blue, and dampen the blue-violet light when erythrosine plates are used, so that with these satisfactory

Fig. 9.

- I. The absorption curve of naphthol orange ... 1 : 500
II. The absorption curve of ammonium bichromate 200 : 1000

'colour correct' monochrome landscapes or copies of pictures may be made." Eder then states that the 1 : 1,000 solution is a very good correct damping solution for erythrosine plates and corresponds to the bright yellow glass screens, whilst the 1 : 100 solution is a deep screen, and these may be adopted as standards.

Ammonium bichromate solution, 20 per cent., is a very powerful absorbent, and may even be used 1 cm. thick as a selection filter, for trichromatic work, but it is not correct. A correct and practical filter is naphthol orange 1 : 500, the absorption of which is shown in Fig. 9. The naphthol orange used by Eder is "Orange II." of the Badische Anilin u. Sodafabrik, a tropaeoline, the soda salt of sulphanilic acid-azo- β -naphthol. Tolan red is not a satisfactory filter, but it makes in the stronger solution an excellent dark-room light filter.

For three-colour collotype the negatives must, of course, be reversed by one of the well-known methods.

In the half-tone block process the correct adjustment of the stops and exposure, as well as the suitable shape and variation of the stops are all-important, and therefore Dr. Eder gives the following data of the process used in the KK. Lehr- u. Versuchsanstalt, Vienna, with electric light and Voigtländer's apochromat collinear or Steinheil's orthoscope of 40 cm. focus

I. YELLOW PRINTING PLATE.

Filter = Plain water.

Plate = Wet bromo-iodide collodion.

Preliminary exposure on white paper = Circular stop F/50, 40 seconds.

Exposure on subject = F/25—F/18 circular stop, 2—3 minutes.*

Exposure on subject = Square stop () F/12, 40 seconds.

II. RED PRINTING PLATE.

Filter = Ammonium picrate solution 1 : 200 ... 30 cc.

Water ... 85 cc.

New patent blue solution 1 : 1,000... 5 cc.

Plate = Albert's emulsion with monobromofluoresceine.

Preliminary exposure on white paper = Circular stop F/50, 30 seconds.

Exposure on subject = Circular stop F/25, 2 minutes.

Exposure on subject — Square stop, as above, F/18, 1 minute.

(If harder or more contrasted negatives are desired, a third exposure, with square stop, F/18, of 20 seconds, should be given.)

III. BLUE PRINTING PLATE.

Filter = Naphthol orange 1 : 500

Plate = Collodion emulsion with ethyl violet monobromofluoresceine, as described above.

* The smaller stop F/25 is used for great reduction of size up to one half. The larger stop for smaller reduction up to equal size.

Preliminary exposure on white paper = Circular stop, F/50, 40 seconds.

Exposure on subject = Circular stop, F/25, 1½—2 minutes

Exposure on subject = Square stop, above shape, F/18, 50 seconds.

The collodion emulsion negatives should be developed with hydroquinone developer, fixed with hypo, and treated as ordinary half-tone negatives, iodised to a yellow colour with iodine-iodide solution, reduced with cyanide, and blackened with sodium sulphide. The dried negatives should be coated with 5 per cent. gelatine solution, and then varnished.

Although of minor interest, the following curves are included:

Fig. 11.—Absorption curve of ammoniacal copper solution (CuSO_4 , 30, water 1,000, NH_3 q. s.)

Fig. 12.

The upper and longer curve shows the spectrum sensitiveness of gelatino-bromide of silver, the lower and shorter curve that of iodised collodion. The absorption curve of methyl violet 1 : 10,000 is shown in the black curve above, Fig. 12.

Fig. 13.

The uppermost and complete curve shows the sensitiveness of a red sensitive gelatino-bromide plate with a generous exposure; the middle curve the same with a shorter exposure. The lowest figure shows (1) the absorption of Tolan red 1 : 1,000, and (2) Tolan red 1 : 4,000, Fig. 13.

Fig. 14.—Absorption curves of auramine I. auramine 1 : 15,000. II. auramine 1 : 800.

In all the above absorption curves the wave lengths and Fraunhofer lines are shown below, and the extinction coefficients right and left of each curve.

CRYSTALLISATION UNDER THE MICROSCOPE.
I.

In a previous issue of this journal, the writer reproduced some photo-micrographs of pyrogallic acid crystals. The growth and formation of these crystals when observed under the microscope affords a very interesting and curious spectacle, as the accumulation of crystals from the first visible speck till the complete evaporation of the solvent in the field of view, can, with the expenditure of a little time and trouble, be readily followed. A low power objective should be used, a $\frac{3}{4}$ in. or $\frac{1}{2}$ in. glass being the most suitable for the purpose.

For observing the formation of crystals, pyrogallic acid dissolved in acetone makes a very convenient solution. With water as the solvent, evaporation takes place very slowly, except the solution is placed on a glass that has been previously warmed. Ether evaporates too quickly, and the crystals begin to form almost immediately the solution is placed on the glass. Methylated spirits give good results, but is not equal to acetone. The crystals are more varied in character when acetone is used than

Photo-micrograph of pyro-crystals with straight radiating lines. 2" obj.

those obtained with pyro or methylated spirit, and very beautiful results are obtained by the use of this solvent.

A few drops of a fairly strong solution should be placed on a clean glass slip and spread evenly over the surface; it is then placed on the microscope stage, and the objective is focussed on any specks that may be in the solution, so that no time will be wasted in obtaining the focus when crystallisation begins.

When a crystal is formed, that part of the slide is moved into the field, and the glass is kept moving to follow the course of evaporation. The crystals form very rapidly, and shoot out into straight lines across the field of view. It will be found, as a rule, that the deposits are formed in a series of shell-like designs, the lines of each shell radiating from a common centre. The most remarkable feature of these crystalline deposits, is the wonderful evenness and regularity of the radiations. This regularity is shown in a striking manner in the illustration given here from a photograph of pyro-crystals, taken with a two inch objective. Straight lines radiate in all directions from the centre of the plate, and are arranged in regular intervals

like the spokes of a wheel. This photograph was taken from a solution of pyro in water. With spirituous solutions, the radiations are not quite so regular, and are generally curved towards the centre.

The crystals will sometimes be observed to form in patches over various portions of the glass, at other times crystallisation begins near the edge of the solution, and from a single point spreads rapidly and evenly over the whole plate.

A curious feature of crystallisation is that a specially rapid action can be set up in one part of the glass which effects a complete deposit of crystals in a very short space of time. This rapid crystallisation often overtakes another isolated and slower moving deposition, and the more powerful force immediately surrounds and passes beyond the weaker, leaving the latter with its distinct markings as a kind of island in its wake. The lines of the more rapid deposit will not be deflected or altered by the obstacle, but continue till they meet another equally vigorous action, or the whole space of the plate is crystallised. This curious effect of the power of crystals to cause a rapid deposition of others is one of the most interesting features of the phenomenon of crystallisation, and will often be noticed when the deposition is being observed under the microscope. The observer will find considerable difficulty in seeing the first crystal form, but if a few dozen prepared glasses are carefully watched, deposition will commence in the field of view of two or three of them. For the purpose of observing the first crystal form, the glass slip must be kept in one position, as moving the solution would prevent accurate observation. The initial crystal is usually first visible as an oblong speck, and immediately becomes the centre round which other crystals rapidly form.

Straight lines are formed, and these move quickly across the field of view; when followed, they are generally found to keep their directions and shape till a similar deposit is encountered, or the edge of the solution is reached.

When the crystals are being formed in straight lines, like those in the reproduction, it would be thought that a speck of insoluble matter on the glass slip would attract the crystals, and deflect them from their course, but this does not occur, and even a large obstacle in their track does not impede progress, except it lies directly in the path.

In the foregoing paragraphs the only substance referred to is pyrogallic acid, this is specially mentioned because it will be found in every photographers dark room, and is besides soluble in all spirits or water. There are, however, any number of chemicals that will give beautiful effects of crystallisation, and most of them will form with some characteristic tracery. All kinds of sugar solutions, for example, form splendid designs in crystallising, but with sugar the polarising apparatus should be used.

No satisfactory explanation, or even working hypothesis, has yet been given as to the cause of the phenomena of crystallisation and the reason why some substances crystallise in elaborate and delicate structures, while other, in many respects similar, bodies are deposited from solution in an amorphous mass, with no definite arrangement of particles.

J. I. Pigg, F.R.P.S.

THE Röntgen Society's next ordinary general meeting will be held on Thursday, April 7th, 1904, at 20, Hanover Square. A large and varied exhibition of novel apparatus is promised by different makers. Tea and coffee will be provided. Smoking will be permitted. Members are especially invited to send skiagrams, tubes, or any original apparatus that has been used in connection with the work of the Society. Members living at a distance and unable to attend are invited to forward anything they have of interest to the Society's Room, 19, Hanover Square, addressed to J. H. Gardiner, Esq., who has kindly undertaken to see that they be exhibited, and returned to the owners within fourteen days of the meeting.

INTENSIFICATION WITHOUT METALLIC SALTS.

[A paper read before the London and Provincial Photographic Association.]

My subject, I must acknowledge, is not one calculated to inspire you with much enthusiasm or eagerness to listen to my humble remarks upon it. But this time there is just one saving clause, and that is, that it is to be done without the deposit of any metal upon the silver image in the film. With this qualification you may bear with me.

I have heard the idea that we should think of intensifying our negatives ridiculed with great energy. Still, I believe that there are reasons to expect that the photographer who desires a certain effect in his print will occasionally resort to intensification. There has been for a long time past a preference for soft and full-toned images, and most photographers aim to get thin and delicate negatives. Striving with all his means to avoid harshness, he will sometimes find the result too thin a negative to give the print he wants, and so must use some method of intensification. I find that as a rule the careful worker does not require a very great amount of increase in density; but an increase is necessary at times to give that

use of this process by me was during the year 1890 or a little earlier. I then used to intensify the image on bromide paper, and I have here some strips of a print intensified by this means, which have not faded in the least. These were shown at a meeting of this society at the time I mention. You will see there is one strip which was intensified with Wellington's silver formula; this has faded very much.

These pieces form a valuable proof of the permanence of this process, which is carried out by rehalogenising the silver in the film, and redeveloping with various developers, and the amount of increase of density with some developers is truly astonishing.

My attention was directed to the suitability of this process for the intensifying of negatives about eighteen months ago, when I used it for the removal of some stains from a negative brought here by Mr. A. L. Henderson. I did not tell you at the time how I accomplished this, but I tell you now. The film was chlorised, washed, and redeveloped, when it was found that the stains had disappeared, this proving pretty clearly that they were not silver spots and stains.

fullness of image which the weak negative cannot. There are, of course, as you know, many causes which tend to the production of negatives which are too thin to give a presentable print. The greater the variation in subject and conditions, if one has the desire for softness in the result, the greater are the chances for the necessity of intensification. Now that we have arrived at the conclusion that we sometimes require it, I will talk of the means of producing an increase of density.

The methods in use, I believe, all involve the deposit of either more silver or some other metal upon the image. Many of them are very unstable. Two of the negatives which I shall show you this evening I found in a most terrible condition, caused by being intensified with the ferricyanide and uranium method. The surfaces of them were covered with dense iridescence. This I removed by friction with a rag pad and methylated spirit. Then I removed the intensification by soaking in ammonia and water.

I have now intensified them by the method which I shall describe to you. This process I believe I can safely say is quite permanent, as nothing is added to the image which can fade. I have some evidence to show you in this direction. The first

The image may be chlorised or bromised. The following formulae have given satisfactory results:—

TO CHLORISE.

Bichromate pot.	5 grains.
Chloride pot.	10 grains.
Hydrochloric acid	4 minims.
Water	1 ounce.

TO BROMISE.

Bichromate pot.	5 grains.
Bromide pot.	10 grains.
Hydrochloric acid	4 minims.
Water	1 ounce.

The bichromate may be kept ready by dissolving $\frac{1}{2}$ oz. in 5 oz. of water. Take 50m. of this to each ounce of solution you require. This might be used stronger, but the result would be the same, only it would act a little quicker. The negative is soaked in water, or put direct into the solution. I advise that it is kept for a little time after it is bleached right through. The plate is then thoroughly washed; I have found thirty minutes ample. I then choose the developer accord-

g to the amount of increase I require. I will now call your attention to the strip negative of graduated exposures, which I have made for the purpose of showing you the effect of chlorising or bromising, and of several developers. The whole of this series is one exposure, and, of course, developed at the same time (see illustration). The exposures and development (metol) were worked to produce a poor negative, which would not give a presentable print. You will see by the strip marked O that it will not do so, this piece having received no treatment. I must tell you that No. 7 has been intensified with mercury followed by ammonia and water. This I made as mark for comparison as at the present time, I dare say, it is used more than any other intensifier. No. 2, redeveloped adurol, gives very high increase; this was chlorised. But No. 12, which was omitted and redeveloped adurol, gives a very considerable increase—in fact, not far away from mercury. Nos. 5 and 6 were chlorised, washed, and No. 6 was exposed to light for the period of three tints of a Wynne's meter, developer metol; the one exposed to light is the denser. I have since doing this found that by prolonging the development for an hour more the same effect may be obtained as by the exposure. I must tell you that all these experiments have been carried out in the presence of a gas flame in a room where weak daylight enters when the door is open. Nos. 10 and 11 were bromised, washed, developed with metol, after No. 11 had been exposed three tints of Wynne's meter. These are up to mercury, No. 11 showing slightly more than No. 10. No. 1 chlorised, No. 9 bromised, and both developed with hydrokinone, show considerable increase, No. 9 slightly more than No. 1. No. 13 chlorised, No. 14 bromised, both exposed to three tints Wynne, developer pyro 2 gr., soda 4 gr., sulphite 4 gr. This gives great density; No. 14 much more than mercury. No. 4 chlorised, No. 8 bromised, both developed with pyro 2 gr., ammonia 2m., sulphite 4 gr.; these are up to mercury. No. 4 a trifle less of the two. No. 3 is chlorised, developed pyro soda as Nos. 13 and 14. Nos. 15 and 16 were iodised, compared with a 2½ per cent. solution of sulphite of soda, or 10 gr. 1 oz. of water, washed. This would not develop after any amount of exposure to light. This fact, I believe, is generally known—that you cannot develop an image on iodide of silver gelatine. This I have found a way of doing, but am debarred by the use of my paper. In No. 16 I reduced the silver by a weak solution of sulphide of ammonium. You will see there is very high increase of density. Temperature plays its part in these as in other chemical operations. If the temperature is below 60 F. the redevelopment is very slow—in fact, sometimes will be as much as ten minutes in starting; but if it is above this the development completed in from two to ten minutes. If you wish only to intensify the delicate tones you can do so by soaking the plate in water, then slightly chlorise the surface of the plate, then wash and redevelop. In this case you must have plenty of solution so that it will act all over the plate at once. The results by this process almost smack of a little photographic legerdemain, as we get, or appear to get, something out of nothing. In some cases the brown-coloured image consists of greater printing value; but where this is not the case, as with hydrokinone, there is great increase in density. In one negative I show you the image was a weak brown, and it was developed hydrokinone and you will see by that portion it is black. I must remind you that none of these prints from negatives have been shaded in the printing. You might be led to think so by the effects they show.

REDUCTION OF DENSITY.

With a very slight variation in the process it can very actually be used for reducing density, perhaps most parti-

cularly in the reduction of contrasts. By this method you can reduce contrasts to any extent you please. To proceed, you chlorise the image, wash, then redevelop; it must be carried much further than the density you require; then rinse with water, and put in a hypo bath. The peculiarity of this process is that you do not only reduce the densest parts, but you increase the density of your delicate tones according to the developer you use. This is what is very frequently required, but I know of no other process that will do this. In the use of persulphate of ammonium, a trifle is lost in the shadows. If it is desired to take a thin coat off the image, slightly chlorise, wash, and fix. All the portraits I show you treated by this method are very old, and I think they will mark a record for their superlative badness. The improvement in them is better seen than described. J. S. TEAPE.

PRINTING, AND OTHER MATTERS.

By THE AMATEUR OPTICIAN.

I AM inclined to the view that matt surface printing out paper is somewhat neglected by our amateurs. Why this should be so I have no idea. The paper is tough and fairly strong—certainly makes more so than others; it is easy to work, prints quickly, keeps in good condition a reasonable time, is susceptible to all the recognised baths, and has a delightful surface, which takes the colour and spotting brush readily. If treated with an alum, or formalin, bath—after washing, and before the final washing—it may be dried neatly and handily between folds of blotting paper, and kept flat. It is not troublesome to mount, and, as I have said, takes the usual spotting mediums with no trouble whatever. Any amateur of the reasonable order who likes a nice clean print, with detail and pleasant colour, should go in for the matt P.O.P.

I agree all the way with "Free Lance" on the matter of residues. For many years I have never ceased the recovery of silver. Toning baths, in amateur use, are perhaps not much worth, but "fixings" from plates and paper, always in my practice, are put into a tub and treated in the orthodox way, so as to yield, in course of time, a fair crop of sulphide. Anyone who can do so may make more out of his residues than he would, quite naturally, otherwise do through a refiner—if he is able to turn the recovered silver to some purpose in his own practice. The chemist, for instance, will use the residue—which may be easily and quickly turned into oxalate or nitrate of silver—for making marking ink or hair dye, the former having by far the best sale. A very good formula is the following:—

Silver oxalate	1 oz.
Ammonia solution, .880	1½oz.
Mix, and add	
Archil	2 oz.
Gum acacia powder	1½oz.
Water to make	8 oz.
A dye which has had a very fair sale for many years may be made from the formula appended:—	
Nitrate of silver	grs. xx.
Sulphate of copper	grs. vj.
Ammonia solution, .880	q.s.
Rose water to	6 drs.

Dissolve salts in water (½oz.), add the ammonia a few drops at a time until solution is quite clear and bright, then make up to six drams. In addition to the above I have turned the residue into caustic pencils, using what is known as a "bougie" mould. They were not, I confess, so slightly as the usual commercial article, but they were saleable and effective.

I fear I have said some hard words about bromide prints in these columns at various times, but my readers will have noticed no doubt that I draw a distinction between the bromide print *per se*—the bromide of the professional photographer and of the

amateur who is wishful to attain to a similar standard of technical work—and the art photo, chemico bromide, which is, happily, seen nowhere out of the exhibition rooms. Quite naturally I take an interest in the matter, because the process has been used by me from the earliest days, when the enthusiast got sample sheets at one and sixpence a time from Greenwich; when demonstrations were widely advertised and attended by crowds of photographers from near and far, anxious to see enlargements made so easily with the new paper, when moreover, it was a bold thing, and somewhat risky, to do your exhibition prints on the new paper—and show them! I write from experience, because up to three years ago I had a frame for bromide prints which were shown in a certain exhibition eighteen years ago, or thereabouts, and were the only bromides therein. The frame and contents unfortunately came to grief in a fire, but at the time were very clean, and of good colour. I am ashamed to confess that they were printed without clouds—as indeed were many other photographs—otherwise they were technically good. What effect they had on the judges was, however, quite negative. Whether they quite knew and understood what the prints were is doubtful. Anyway, no one, so far as I heard, went into ecstasies over the artistic tone and surface, and for all that, with the one single, but important, incident of the clouds, they were, I repeat, when last I saw them, a very good average print.

No one disputes the fact that bromides may be toned in a great variety of colours, more interesting than beautiful, perhaps, and doubtfully permanent. But, after all, is there anything more effective in this way than the rich, velvety, engraving black, which may invariably be got when the exposure has been accurately timed. In the course of his address to the R.P.S., Mr. Winthrop Somerville made use of the following sentence, which puts into a very compact space what has made columns of printed hints on bromide work:—"Development may be either rapid or slow—the latter easily obtained by diluting the bath—but however the developer may be slowed down, development should be carried to the farthest limit of the bath." Very briefly, I may tell the young bromide printer that he has only to follow up this hint and he will have no need of intensification or toning baths. How easily things go wrong with bromide prints. Lantern slides are bad enough; they are never off one's mind until dry. Bromide prints are in the same category. Only a few weeks ago I lost half-a-dozen first-rate prints in the simplest way. They had been placed, from the washing water, on sheets of clean blotting paper, and set down for a few minutes upon a bench in the work-room preparatory to being removed to a safe drying cupboard. An assistant started to make some fresh amidol developer, weighing out the chemical only a few feet distant from the prints. Long before the latter were dry several dark brown spots came out on each, and, needless to say, the prints were as good as waste paper. Minute particles of the fine light powder would be, no doubt, conveyed by the slightest movement in the air, and would settle upon anything damp in the vicinity. The moist surface of the bromides would, of course, receive their share and suffer accordingly.

ROYAL Photographic Society of Great Britain.—Ordinary meeting, Tuesday, April 12th, 1904, at 66, Russell Square, at 8 p.m. "Demonstration of the Author's Method of Determining the Focal Length and the Aberrations of a Photographic Objective," by Reg. S. Clay, D.Sc.

MESSRS. Charles Smith, Sons, and Co., Limited, Deritend Bridge, Works, Birmingham, the well-known manufacturers of gas and electric fittings, send us a useful diary and blotting pad for the editorial table. In addition to a diary interleaved with thin blotting, there are special spaces for engagements, and a large pad for writing upon. The book forms a handsome addendum to one's office requisites. A catalogue of the company's specialities is also to hand. This is a beautifully-illustrated production, in which the half-tone process is lavishly employed.

A SIMPLE CURRENT REVERSER FOR SPARK COILS.

A SPARK coil is very incomplete without a commutator. One of a very simple kind, and much easier to make than the usual variety fixed to coils, is figured below. This is a modification of one illustrated in Mr. Hare's book on large induction coils, and on all fours with a reversing switch fitted by Carlisle and Watson of New York (I think) to their model motors and electric cars.

A. is a piece of stout sheet brass, about 1in. by 3in.; in the

centre of this a hole is made to exactly fit a piece of brass tubing B. (triblet tubing used by makers of fishing rods will do for this).

B. is about an inch in length, and should be soldered to A. and fixed upright.

C. a piece of brass tubing half an inch longer than B, through which it passes; it should make rather a tight fit in B. In one end of C. fix, by soldering, a small brass bolt, the head of which should just go in the end of tube, and may there be fixed. At the other end of C. drill two holes exactly opposite each other, and large enough to take a piece of stout brass rod, J. (about two inches); this also may be soldered.

D. is a thick disc of ebonite. This is secured to the bottom end of C. by, having drilled a hole, passing it over the brass

screw and securing it with the nut. It follows that if the handle or T-piece be turned, the ebonite disc is revolved, anything mounted upon it being quite insulated. The T-piece should be fitted so that the ebonite disc is kept close to the plate A., and works without shake.

E.E. are two brass studs securely inserted at opposite sides in the under side of the ebonite disc; securely soldered to each is one strand of the best silk and rubber-covered twin flexible

ire. The best way I think to do this is to get two pieces of the smallest gauge copper or brass tubing, 3-16th, say; drill a small eye near one end, and having bared a strand of the wire pass through the hole and out at the end. Then plug this end with a piece of brass rod, and make a perfect joint with solder. The two studs, or short tubes, being done in this way, may then be securely fixed to the disc as shown. They are, of course, perfectly insulated one from the other by the rubber and silk covering.

The brass platform, A., is mounted on two wood (mahogany) blocks, G.G.; these again glued to a gas block. Two terminals are then attached, as shown, H.H., and hard brass or German silver springs adjusted, R.R., so as to make perfect contact with the studs E.E. See here the plan, Fig. 2, where is shown the under side of the ebonite disc, the two studs, and the two springs pressing against them.

Ebonite or wood handles are fitted to the T-piece, and the protruding end of C. may be covered with a little ebonite cap.

The twin wire is attached one strand to the contact pillar and the other to one of the primary wires on the coil. The wires from the battery are then brought to the two terminals, H.H. The handles being in a line with the base, as in the figure, a current passes, which current is reversed if the handles are turned the reverse way. With the handle set at right-angles to the base the current, of course, is switched off.

Mr. Hare's remarks accompanying his design of switch may be quoted:—"In the ordinary commutator there are four points where resistance may be found, viz., at the two bearings of the cylinder, and at the two springs. These may be reduced to two, and the contact much improved."

Exhibitions.

THE NORTHERN PHOTOGRAPHIC EXHIBITION.

THE intention to hold a Northern Photographic Exhibition annually in succession at Liverpool, Leeds, and Manchester, and organised by the photographic society of each city, respectively, in turn, is a good idea, the matter from whence derived. It has fallen to the lot of Liverpool to start the ball rolling, and nothing but congratulations can be offered to the energetic Amateur Photographic Association of the city on the energy for the thoroughness with which they have entered on their task, and the unqualified success they have achieved in accomplishing it. Whether it was the avowed intention of the Liverpool Society to rival the exhibitions of the Royal at the New Gallery we cannot say, but an exhibition of nearly 800 selected works by the foremost photographers of the day; admirably hung in a suite of rooms acknowledged to be the best in the kingdom for the display of pictures; about 1,000 first-class competition lantern slides displayed in a novel manner that can only call for admiration; a fine collection of trade exhibits, a series of instructive and interesting lectures during the run of the show, and the whole officially opened with great éclat by the Lord Mayor of Liverpool giving a fashionable soiree, stage managed with every ability—offers such material for comparison. That the Liverpool Society was fortunate in securing such magnificent quarters for their exhibition at the Walker Art Gallery there can be no denying, and to their credit be said they have endeavoured to make their show worthy of its environment.

The exhibition rooms of this spacious institute are peculiarly well lit and commodious, and, moreover, the civic gallery is the one, if not the only, place in Liverpool to which the public will come readily to look at pictures. During the winter the committee has worked hard to make the exhibition a success, under the chairmanship of Dr. Llewellyn Morgan, and with the indefatigable Mr. C. F. Inston as honorary secretary. It was decided that the prize awards should be in the form of a decorative plaque, and in order to secure a new and original design for this, a special prize was offered to the students of Mr. C. J. Allen

at the School of Architecture and Applied Arts. This was won by Miss Phoebe McLeish, with a clever composition very reminiscent of the poster designed for the Southsea Exhibition three years ago.

Of the four vice-presidents, Mr. E. Rembault Dibdin, took in hand the production of the catalogue—a splendid book, worthy of the exhibition. Among its attractions a specially designed cover, a photogravure frontispiece, a colour reproduction in facsimile of Lord Leighton's "Bath of Psyche," and numerous full-page half-tone blocks reproducing pictures on the walls. Dr. C. Thurstan Holland was chief of the Hanging Committee, and right well has he accomplished his task—the pictures being hung with commendable taste. Mr. Fred. A. Schierwater has charge of the finance, and to Dr. John W. Ellis fell the task of presiding over the Lantern Slide Section. There is little doubt that the original and attractive form in which the collection is displayed is one of the features of the show. One of the smaller rooms has been completely darkened, and the slides, securely fixed in perpendicular frames around the walls, are illuminated by electrically lit reflectors placed at an angle behind. The slides can thus be viewed by transmitted light, with comfort and dispatch, while a comparison of the competitive sets is made easy. It is a capital idea well carried out. Needless to say, Mr. C. F. Inston has been practically omnipresent throughout the whole period of organisation, and his capable management of the entire affair has undoubtedly secured the complete success of the venture. We understand that all pictures entered passed before the judges, who were themselves the selecting committee, and about 250 were rejected. In the pictorial sections twelve copies of the prize plaque were awarded to competitors by the judges, who were Messrs. Harold Baker, A. Horsley Hinton, and Alexander Keighley. Mr. Thomas Huson, R.I., R.F., who was to have acted with them, was unfortunately prevented by illness. In the scientific section the judges were Mr. Douglas English, B.A., and Dr. Charles A. Kohn.

We wonder why it is that at most exhibitions, particularly those with more or less ambitious intent, as in the present instance, there is always one prominent award that does not meet with approval.

When a picture is dubbed "the best picture in the show" and receives the premier award as such, one certainly looks for something above the average. Whether the visitor will be disappointed at Liverpool will depend much on the individual. No. 235, "Storm Breaking," by J. H. Canevali (Hon. Treasurer of the Exhibition), receives this distinction (silver gilt plaque), and in consequence emerges from a comparative obscurity to a somewhat unenviable notoriety. We say comparative obscurity, because a small print mounted on a broad glaring white mount in a frame with a gilt slip, can never be altogether obscure in the company of a collection of tastefully framed pictures. We wonder what its effect will be on this earnest body of workers, who after strenuous effort, have not only brought together a fine and representative collection of the best pictorial work by photography, but have penetrated into the very stronghold of art in one of the greatest art-loving cities of the north? The artistic patrons and habitués of the Walker Art Gallery who come to see the show naturally turn for information and inspiration to the "best picture in the exhibition," as representing the best that this claimant for entry to the Temple of Art can produce. They are shown No. 235. The moral is obvious.

Three silver plaques are awarded, the first of which goes to Dr. Llewellyn Morgan (Chairman of the Exhibition Committee), for No. 341, "The Font, York Minster," which has good quality, but is otherwise quite ordinary in conception, especially in comparison with some of the adjacent masterly architectural studies by Fredk. H. Evans. It is a curious fact worth noting that this print is also mounted on a white mount, which somewhat "kills" it. Is this the first sign of a return to the type of mounting popular twelve or fourteen years ago at exhibitions, before the vogue of the closely framed photographic print? We wonder.

No. 157, "In Pensive Mood," by J. Spark, secures the second silver plaque. It is an unconventional figure study, but nevertheless good straightforward work. The sitting figure does not strike us as taking its proper place in the frame. The third silver plaque goes to J. C. Coultas for No. 199, "The River Aire at Leeds," a charming picture, broadly and poetically treated, containing good composition and effective technique. W. T. Greatbatch takes the first bronze plaque with his well-known picture, "The Orchard" (No. 151). This picture received the R.P.S. medal a year or two ago, and has a charm of its own that could not be overlooked.

Another R.P.S. medallist, C. F. Inston, deservedly scores with his equally well-known "Whence, and Whither?" (No. 173). An excellent reproduction of this veteran appears in the catalogue. Mrs. G. A. Barton's "Village Belle," a good example of this worker's charming figure studies, secured the third bronze plaque, while the fourth is awarded to T. Lee Syms for "A Portrait" (No. 357). This is one of the best portraits in the room, and is, moreover, straightforward photography. It has an academic touch about it that removes it far beyond some of the efforts in gum in its vicinity.

Looking round the exhibition we note many good things deserving of notice. C. F. Inston's fine sea- and shipping studies attract at once, and leave a lasting impression of good sound work, (No. 9) "After Rain," (191) "The Storm Lifting," (464) "The Sea Shone Glorious as a Silver Shield," and (345) "A Study," are, in addition to his medalled picture, very fine indeed. The last is a particularly happy portrait. The fine works lent by Messrs. A. Horsley Hinton and Alexander Keighley, of course, call for immediate attention, and represent landscape photography at its best. Charles Job is also represented by three of his charming pictures that call for nothing but praise.

William Crooke's dignified portraits, too, teach a lesson in good, clean photography that ought to be taken to heart by some of the slipshod workers in gum, whose portrait work will be found on the walls.

Many other well-known workers have contributed specimens of their work to the exhibition, and it is difficult to imagine what the award list would have been had all the non-competitive work entered the lists for an award. One of the finest pictures in the exhibition is undoubtedly (No. 10) "Winter," by Thos. Wright. The quality of this snowscape is superb, while the composition is beyond reproach. Why, also, the judges overlooked Percy Lewis's masterpieces will probably excite considerable speculation. No. 122, "A Venetian Waterway," (148) "An Italian Fruit Stall," (352) "A Misty Morning," (131) "An Old Archway," are each perfect specimens of camera craft, the last being probably the best thing Mr. Lewis has done, which is saying a good deal. Notable work by W. R. Bland, Ralph Robinson, Harold Baker, Fredk. H. Evans, F. M. Sutcliffe, J. Craig Annan, and David Blount, also calls for notice, while among other well-known contributors are J. Page Croft, J. C. Warburg, Miss Agnes Warburg, J. M. Whitehead, W. A. Clark, W. A. I. Hensler, Arthur Marshall, Dr. C. Grindrod, J. Appleby, and F. J. Mortimer. We missed the latter's well-known "Wind Sea" from the walls, and wonder why it was not sent.

Space forbids mention of many other pictures in the collection that call for notice. In Section II. (Scientific and Technical Prints), some fine examples of X-ray work is shown by Dr. Thurstan Holland. Realistic photographs of live snakes and lizards by Frederick Graves; bird pictures by O. G. Pike; dainty photographs of "Mouse and Marten," by Douglas English, and a clever series of X-ray work by W. M. Martin, the latter being awarded bronze plaque for a series illustrating the development of the frog.

Section III. (Lantern Slides, Pictorial), includes, as we have mentioned previously, a very fine collection of slides indeed, both in regard to numbers and quality. The silver gilt plaque goes to James Shaw for an excellent set of great merit. Silver plaque to H. J. Houghton for a fine set of snow scenes; and bronze plaque to Ellis Kelsey for a series of figure studies at night. In the section for Scientific and Technical Slides, the awards are silver gilt plaque, Fred. W. Saxby for three sets of "Polycistins (fossil radiolaria)" by dark field illumination; silver plaque, B. H. Bentley, for studies in the "Pollination of Flowers."

In Section III.—Stereoscopic Slides—a bronze plaque goes to F. G. Tryhorn for a set of six.

The trade exhibitors make a goodly show and their stalls occupy the whole of the "Marlborough" room and part of the large water-colour room. At night the "Marlborough" room presents a remarkably effective appearance—the stalls being illuminated by electric light, and the scene is a busy one. The Brooks-Watson Camera Co., Ltd., of Great Homer Street, Liverpool, in particular has a very elaborate stall surmounted by a gilded cupola and graceful hangings. On the occasion of our visit the energetic and genial manager, Mr. Bynoe, was exploiting the firm's wares, which include the Rajar changer, the new Rajar

camera, and the Clerion films. Messrs. Sharp and Hitchmough have a central stand, and display a very fine range of the Aptsu specialties including hand cameras, enlarging lanterns, backgrounds, lantern sheets, and, in fact, everything that the photographer can possibly desire. Mr. Hitchmough will attend to him personally at the stall at the factories, 101 and 103, Dale Street, Liverpool.

Messrs. J. Griffin and Sons, Ltd., of Sardinia Street, London, fortunate in having secured a stall in the exhibition room itself. Being thus isolated, their representative is likely to come in for a full share of attention, and which he is sure to take advantage of to demonstrate the various grades of velox and carbona paper on view, and of specialties of this well-known firm, including cameras, printing frames and the new bromide linen. In Room 2, Messrs. Evans, Sons, Lesch and Webb, Ltd., of 56, Hanover Street, Liverpool, also have a stall and show the "Barts," "Hanover," and other cameras, developments, etc. On the wall in Room 2 are collections of professional work by Julius A. Kay, of Bold Street, Liverpool; Richard Brown, 35, Bold Street, Liverpool, who shows carbon reproductions from the permanent collection of pictures in the Walker Art Gallery (by permission of the Liverpool Corporation), and Messrs. Brown, Barnes, and Bell, Bold Street, Liverpool, who show enlarged and direct portraits.

In Room 4 the trade stands include, in addition to those already mentioned, attractive displays by Messrs. J. Lizars, 71, Bold Street, Liverpool ("Challenge" cameras and all "Challenge" manufactures); F. V. A. Lloyd, 17, Lord Street, Liverpool (Sanderson hand and stand Mirals and Reflex cameras and general apparatus); W. H. Tomkinson, 81, Dale Street, Liverpool (half-plate outfits, hand cameras, etc.); Messrs. W. L. Parkinson, Ltd., 62, Dale Street, Liverpool (all photographic materials, etc.); Messrs. Archer and Sons, 73, Lord Street, Liverpool (their well-known hand and stand cameras, lanterns, etc.); Julius A. Kay, 66a, Bold Street, Liverpool, and at Southport (direct and enlarged portraits and miniatures on ivory); Messrs. Mowll and Morrison, The Arcade, Lord Street, and 45, Hardman Street, Liverpool (examples of portraiture, etc., etc.); the Autotype Company, London (display of Autotype reproductions of pictures, etc.); F. J. Cooper, 32, Hamilton Square, Birkenhead (examples of portraiture, etc.).

WOLVERHAMPTON PHOTOGRAPHIC SOCIETY.

THE Wolverhampton Photographic Society's third annual exhibition was opened by the Mayor of Wolverhampton (Ald. Levi Johnson) at the Y.M.C.A. Rooms, Darlington Street, on March 24th.

As the exhibition is a local one, perhaps the Classes I. and II. for members will be first sought by visitors. The first-named is open to beginners who have never taken an award, and Class II. is open to all members. Some of the pictures have been shown in the principal exhibitions in London. Amongst them are examples by Messrs. Reade, Cox, Gale, H. M. Painter, and Murray. Mr. C. J. Reade is represented by some very fine work, the most notable being "The Playground of the Winds," a picture of a windy, blustering day on the sand dunes, with the coarse grass rudely beaten down by the breezes. Mr. Murray gained a certificate at Birmingham with "On Cannon Chase." It is a finely graded picture, and was hung at the Royal Exhibition last year, as was also "George Phoenix," a portrait also by Mr. Murray. Mr. Gale has very good work in the gum process, his Royal Exhibition pictures being particularly striking. Mr. T. Henry Cox shows "the interior of a ruined mill," a difficult subject well treated, and "The Fisherman at the Ford," by the same worker, is a delightful study, although the light and shade are unhappily balanced. Miss Highfield-Jones, a new member, has several capable studies, and her work promises considerable artistic development. "Rhuddlan Castle," by H. M. Painter, and Dr. Turtton's "Bridgnorth," are worth special mention. Mr. E. George, Mr. Vincent Knight, and Mr. H. Lee also show excellent pictures.

In the loan collection, Mr. Harold Holcroft, M.A. (president of the Society), shows 19 pictures by the very finest exponents of photographic art. They include studies from all parts of the world, and were purchased at the leading exhibitions. "Peace," by Alexander Keighley, suggested repose, and, in reality, it is the very essence of restfulness, whilst the treatment is wonderful. "Wind from the West," Mr. A. Horsley Hinton, is a grand specimen of this master worker's art, and whose unique method of construction sweeps aside

of the technical difficulties of the photographer. The loan collection is exceedingly rich in artistic photography, and we may mention the pictures include examples by Mr. Smedley Aston, the late P. Robinson (one of the earliest of pictorial workers), Robert Why, J. Page Croft, the late W. J. Warren, Harold Baker, C. Abbott, Mrs. Barton, David Blount, C. Puyo (Paris), and Bland.

Judges, Mr. W. T. Greatbatch and Mr. A. C. C. Jahn, made the following awards:—Class I. (open to members who have never taken a medal): Silver medal, "A Study," Miss R. Highfield Jones; bronze medal, "A Pool on the Severn," Mr. Fred. R. Turton; hon. mention, "Moorland Farm," Mr. Frederick Turton. Class II., silver medal, "The Mirror," Mr. James Gale; bronze medal, "Geo. Phoenix," Mr. D. Murray; extra bronze, "In an Old Scotch Fishing Boat," Mr. D. Murray; hon. mention, "The Fisherman at the Mill," Mr. T. Henry Cox.

STIRLING AND DISTRICT PHOTOGRAPHIC CLUB EXHIBITION.

On Saturday last the Stirling and District Photographic Club opened its second annual exhibition in the Corn Exchange, Stirling. The exhibition was presided over by a good attendance, and introduced Sir Alan Stuart, Bart., of Touch, who declared the exhibition open. In all, 45 pictures are shown, including 40 non-competitive, 45 members, and 1 open. The exhibition contains much good work, strong competition being evident, especially in the open classes. The judges were Mr. Wm. Rodger, Stirling, and R. E. Rennie, Kirkcaldy, two well-known professionals. The following are the awards:—Open Classes (sculpture): 1, "Sunset, Whitby," Robert Milne, Paisley; 2, "Evening on the Sand Dunes," W. J. Croall, Edinburgh. Portraiture, etc.: 1, "Solving the Puzzle," P. D. Nairn, Perth; 2, "Auld Struth," John MacLachlan, Blairgowrie. Any Other Subject: 1, "Crypt, Aquilon," P. W. Crane, Heavor; 2, "Roses," Robert Burnie, Glasgow.

A collective exhibit by any Scottish Photographic Federation, Glasgow Eastern Amateur Photographic Association. Memorable (Landscape, etc.): A. Mathers. Any Other Subject: J. R. Lantern Slides (sets of four): 1, S. Goudie; 2, J. Littlejohn.

FORTHCOMING EXHIBITIONS.

April 6-13.—Croydon Camera Club. Hon. Exhibition Secretary, Mr. King, Hurst Bank, Selsdon Road, Sanderstead.

April 8-9.—West London Photographic Society. Hon. Secretaries, Mr. Cockerell, 107, Hammersmith Road, W.; F. C. Hart, 37, Tottenham Road, Acton Hill, W.

April 20-26.—Swansea Photographic Club. Hon. Secretary, W. R. Jones, 14 and 15, Temple Street, Swansea.

April 11-18.—Plymouth Photographic Society. Hon. Secretary, Mr. Grist, 105, Old Town Street, Plymouth.

April 16-23.—Photographic Society of Ireland. Hon. Secretary, Mr. Webb-Smith, care of Royal Dublin Society, Kildare Street, Dublin.

April 24-28.—Devonport Camera Club. Hon. Secretary, A. J. Jones, 78, Charlotte Street, Devonport.

PHOTOGRAPHY in the North of England has suffered a serious loss with the death of Mr. William Thompson, of the well-known firm of Thompson and Lee, of Newcastle-upon-Tyne. Like so many of our great photographic workers, Mr. Thompson began his career as an artist, drifting gradually from a solicitor's office into the ranks of professional photographers. Gifted with indomitable perseverance and energy, he founded a large and successful business devoted to artistic and mechanical photography, specialising in the difficult art of collotype printing, in which he excelled. For many years he was the life and soul of the Newcastle and Northern Counties' Photographic Association, fulfilling the duties of honorary secretary with extraordinary vigour and ability. Combining, as he did, ripe judgment and sound taste in artistic matters, with unusual technical and scientific attainments, a brilliant career seemed assured for him when at the age of thirty-four he passed away on March 27th.

AN INTERESTING EXHIBITION.

To commemorate the foundation of the firm of Burroughs, Wellcome, and Co., a quarter of a century ago, an historical exhibition of rare and curious objects relating to medicine, chemistry, pharmacy. We learn that it will be strictly professional, and scientific in character, and designed to illustrate the development of the art and science of healing throughout the ages. The following is the

CLASSIFICATION OF EXHIBITS.

Section 1.—Paintings, drawings, engravings, photographs, medallions, and sculptures of historical interest of—(a) Distinguished physicians, surgeons, alchemists, apothecaries, chemists, nurses, etc.; (b) Antient British and foreign medical, chemical, and pharmaceutical institutions; (c) Important events of medical, chemical, and pharmaceutical interest.

Section 2.—Rare and curious manuscripts, books, periodicals, pamphlets, and book-plates on, and connected with, medical, chemical, pharmaceutical, and allied scientific subjects.

Section 3.—Letters, prescriptions, autographs, records of experiments, diplomas, licenses, instruments, apparatus, and other personal relics of medical, pharmaceutical, and chemical interest. Apparatus associated with important discoveries in medicine, chemistry, and pharmacy.

Section 4.—Curiosities of medicine—(a) Materia medica of all ages (specimens of antient medicines in all forms). (b) Formulae of all ages. (c) Antient and modern medicine chests—civil, military, and naval. (d) Votive offerings for health, antient and modern amulets, medals, seals, emblems, charms, and talismans. Medical relics of savage and primitive peoples. (e) Corporate insignia and diplomas of British and foreign colleges of physicians. (f) Rare and curious memorials of medical practice. (g) Memorials of medication by animal substances. (h) Memorials of the influence of astrology on medicine.

Section 5.—Curiosities of Surgery—(a) Relics of antient and mediæval surgery, dentistry, and veterinary surgery. (b) Antient and mediæval hospital equipment. (c) Curious anatomical models. (d) Historical surgical instruments, appliances, etc. (e) Corporate insignia and diplomas of British and foreign colleges of surgeons.

Section 6.—Curiosities of pharmacy—(a) Quaint pharmaceutical recipes. (b) Scales, weights, and measures of all ages. (c) Antient stills, mortars, and pharmaceutical implements. (d) Curious bottles, carboys, alembics, ointment jars, drug jars, ewers, mills, etc. (e) Curious laboratory apparatus. (f) Antient prescription books and price lists. (g) Antient counter bills, labels, curious advertisements. (h) Antient pharmacy signs, early shop fittings, and appliances. (i) Early pharmaceutical specialities and specimens of obsolete and curious medical combinations. (j) Old travellers' advice books, curious orders, etc.

Section 7.—Curiosities of allied sciences—(a) Antient herbaria. Abnormal plant forms. (b) Curious magnetic and electrical appliances. (c) Early photographic prints and apparatus. (d) Historical chemical apparatus. (e) Anatomical exhibit. (f) Anthropological exhibit. (g) Microscopical exhibit. (h) Bacteriological exhibit. (i) Biological exhibit. (j) Physiological exhibit. (k) Geographical exhibit.

Mr. Henry S. Wellcome, of Snow Hill Buildings, London, E.C., who is organising the exhibition, invites the co-operation of those possessing any of the articles mentioned in the classifications. Great care will be taken of all objects sent on loan, and packing and carriage will be paid both ways by Mr. Wellcome.

THE Selborne Society's annual meeting and conversazione will be held on Friday, 27th May, at Burlington Gardens (by kind permission of the Civil Service Commissioners) in the Theatre and Halls lately occupied by the University of London. The Committee would be glad of the loan of any series of photographs illustrating the objects of the Society, which are, amongst others, the promotion of the study of natural history, the preservation from needless destruction of such animals and plants as are harmless, beautiful, or rare, and the protection of places and objects of natural beauty or antiquarian interest. Letters should be addressed to the Secretary, Selborne Society, 20, Hanover Square, London, W.

PHOTOGRAPHIC SURVEY AND RECORD OF SURREY.

THE annual meeting of the members who are compiling a photographic survey and record of Surrey was held in the Council Chamber at the Town Hall, Croydon, on Saturday, the 12th inst. The Right Hon. Viscount Midleton (Lord-Lieutenant of Surrey), the President, presided, and was supported by Sir Frederick Edridge (Deputy-Lieutenant), there being also present Lady Edridge, Mr. W. Whitaker, F.R.S., Coun. Keatley Moore, Mr. H. Maclean, Dr. J. M. Hobson, Mr. L. Stanley Jast, Mr. H. D. Gower, the hon. general secretary, Mr. W. W. Topley, the hon. treasurer, and others.

The reports of the various sections showed that during the past year 561 photographs had been added to the collection, making a total of 621. The largest contributors were Dr. J. M. Hobson, who had sent 226, and the Croydon Camera Club, who by means of a competition had forwarded 121 prints. The sections include art and literature, anthropology, geology, natural history and scenery, and passing events.

Viscount Midleton, in moving the adoption of the report and balance sheet, said he would like to say a few words about the scope and object of the Survey. The scope had widened as the workers widened. Substantial progress had been made during the past year, and he found on looking at the report that the number of photographs on the books was now over 600, instead of about 60 last year. They ranged over a very wide field, and combined a number of different objects, each important in their way, and each forming, if it might be so called, a different department. He would deal with them one after another. The earliest of all must, of course, be geology. He did not know that the county afforded any wide field for the study of this particular branch of the work. The strata was well defined and pretty well known. The county might be sub-divided into the area of London clay, which adjoined the Metropolis, with that one ridge of chalk Downs, which, beginning at Tenterden, in Kent, was carried throughout the whole of Surrey, broken only by the valleys of the Mole and the Wey, rising beyond Guildford into that curious prolongation known as the Hogs Back, falling, as it approaches Farnham, and rising again as it leaves the county into the Hampshire Downs. Then they got the Weald Valley, which divided the wealds, and which, he believed, geologists had come to contend must have been an old estuary, for nothing else could account for the appearance of the rounded lumps of chalk as they succeeded each other in front of the Weald, both on its northern boundary in Surrey, and on the southern boundary in Sussex. Beyond that again, came the ledge of green sand, which, he had heard, was upheaved by volcanic eruption in the centre of the Weald Valley, and it broadened out further as it approached the west until the weald of clay was almost obliterated. That tract of county was of considerable interest to the photographer, and there were certain places where the chalk had been exposed, forming a fruitful field for the study of anthropology, the study of the habits and the life of primeval man. A very interesting light had been thrown upon this subject by a recent publication, which had just been issued, and was reported upon by the Anthropological Society of Surrey, which emanated from that immediate neighbourhood. He trusted every one of the objects there mentioned would be subjected to the photographic process, not only to be preserved, but to reach a larger circle of individuals than could ever be expected to see the original specimens. They now came to that section which dealt with art, art in its various phases, and here he very much doubted whether those who, in giving some attention to the subject, were not aware of the wealth of objects which might still be found in Surrey. The Weald, as they probably once knew, was the home of the iron manufacture in Britain. There were two things necessary to make the industry a success, the iron ore and the oakwood trees, which were at that time the only fuel available by which iron ore could be melted. Of course, when in the North of England the iron and the coal were discovered together it became far more cheaper to work with that fuel than to work the iron ore in Surrey and Sussex. One of the best examples, he believed, which remained of the great Surrey Weald iron was to be found in the railings round St. Paul's Cathedral. There were, however, all sorts of reminiscences scattered over the Weald, in the old farmhouses and cottages, of what was then accomplished by Britons, who were really the iron workers of the district, the Saxons never penetrating, but groping round by the seaboard, and until

the siege of Pevensey Castle, in which those Britons who did not in the assault were executed, those upon the Weald were left in disturbed possession of the iron works. There were distributed the farmhouses curious firebricks and firebricks, implements of different coins, some of which he believed had been already taken up by the Society, many of which, however, remained to be taken up. He himself possessed two very striking examples of iron with the Royal Arms, and on asking the late Mr. Godwin Ainslie who was by far the best authority on this subject, he told him it was very little doubt they were old Weald castings, intended for the old Palace of Nonsuch, but there was a considerable surplus left over, and when the requirements of the palace were satisfied these first found their way into the farmhouses and cottages, which they gradually drifted until they were dispersed over the valleys of the Southern Counties. This was only one instance of the numerous objects of art which were still more or less preserved by their owners and which required to be looked up and reproduced by photography. Then there were two other departments—architecture and scenery. He observed with regret that the western part of the county, with which he was more intimately connected, did not seem to have quite its duty in reproducing its objects of interest. He was sorry for it because a cursory review of what was to be found there would show how much there was still to be accomplished. The stately old houses near Farnham presented many examples in shade and sunshine worth reproducing by the photographer—the old keep, the banqueting hall, indeed there was hardly an inch of the old castle which would not repay a visit. At the opposite end of the county they found the palace of the Archbishops at Lambeth, with all its architectural and historical associations. Then there were two examples of Elizabethan houses in Surrey, in Molesley Castle, near Guildford, and Sutton Place on the other side. Both had been to a certain extent modernised, but care had been taken by the owners to keep to the original design and ornamentation as far as possible. Then there were old timbered houses and cottages, some of which, he was sorry to say, were gradually disappearing in and around Godalming and Guildford. Any one had only to walk through the main streets of either of these towns to see how much there was that they could not expect to last for ever, and of which some trace ought to be left behind for those who came after us. There was one old Elizabethan shop, which was famous for its use as Judges' lodging in Guildford, absolutely unique in its design. Godalming was full of old timbered houses, gradually, he was sorry to say, being replaced by modern elevations, but still worth preserving before they were doomed. Guildford Castle was very well worth a visit, and also what remained of Reigate Castle. Then there were the Surrey abbeys. The abbey of Chertsey was said to have occupied three acres, but unfortunately little of that remained except mounds of earth, but there was an abbey between Guildford and Woking, a smaller one, which would well repay the photographer, and also the ruins of Waverley used, he regretted to say, too much as a quarry for the neighbouring houses, but still retaining part of their architectural glories. He had merely touched the fringe of the subject. It was hardly a Surrey locality in which a person well acquainted with the county was not bound to find some objects of interest. Any one went about reproducing ancient architecture—of course, there were some fine examples of modern architecture in the county—would find that certain of the churches would well repay a visit. The difficulty with regard to the churches was that they had almost all been restored, some at one time and some at another, and sufficient care had not been taken to preserve as far as possible the outlines of the original. Still there were a great many churches which were well worth a visit from the photographer, either in whole or in part, and it would be of interest to issue these prints with those in a volume published in the last century, in which a full description of all the different churches in the county was given. Then they turned from architecture to scenery. The scenery in Surrey was unexampled in England. Take the quiet scenery all along the North Downs from Guildford to Titsey Hill, overlooking Limpsfield and the valley. It would repay any amount of trouble taken in reproducing it, particularly in the spring and early summer. There was also the view from Leith Hill, extending over four counties, embracing all the valleys of the Weald. After mentioning one or two other famous hills, Lord Midleton proceeded to mention other famous objects, as the King's Oak at Tilford, the tree under which Wycliffe was

ve preached; the Silent Pool, which had been restored by the rains to its former beauty, and which many people feared was to dry up in the early part of last summer. He believed the tree was still in existence, under the branches of which King VIII. courted the ill-fated Anne Boleyn, that would be an well worth preserving for posterity. Then, again, there was found in the grounds of the palace at Richmond, from which it said Henry watched for the upward flight of the rocket which announced to him that her head had fallen upon the block, and he was free to marry again. In Kingston-on-Thames there were very ancient examples of early architecture, which were being ably developed by a former Mayor, a great authority upon every- of that kind. He was extremely glad to see that the work of survey was gradually widening, and that very little jealousy of work of the Society seemed to be entertained by the professional graphers, some of whom had lent very valuable assistance, for he was sure the members were heartily grateful. The Archae- al Society at Guildford possessed a very interesting collection, h he was sure would be open to inspection, and probably to graphy, and would bring before those in different parts of the y the really good work which this Society, which celebrated its e in April, was doing. He felt most strongly that this Society the Photographic Survey ought to go hand in hand, for they both engaged in a work which was not a selfish work. They ed to hand down to those of the future the things of the past rved so far as they now might be by the men of the present; wished to quicken the intellects of those who had not now an tunity of seeing in all their freshness scenes which were passing e their eyes, and they wished not to live for this generation alone, or the generation which would follow, so that they might see abits and customs of their ancestors, and it might be that they would still hand down a fruitful record of the times that were e times which were to come. That could only be carried out me society such as that, and he was really glad to see that a r branch was to be formed in an adjoining county, which, he d, would join hands with them, so that they might emulate and then each other's position. He was sure no one who put his into that work would regret having done so, for he would earn ratitude of those amongst whom he lived, and, what was still ndeed, those of the posterity he was not destined to see.

e report and balance sheet having been unanimously adopted, unt Midleton was re-elected president, the vice-presidents were ected, as also were the officers.

an. Moore proposed a vote of thanks to Lord Midleton for pre- g, and said that those who had heard his eloquent speech must t that in their president they had the best possible man they ave for the post, and they all felt grateful to him for coming that evening. Lord Midleton had shown them avenues which d afford food for reflection, showing them the work before them, a mply justified the existence of such a society. He wished to r to their notice some lectures which were to be delivered by ssor Malden in connection with the University Extension lec- and which would prove of special interest to them.

Frederk. Edridge, in seconding, said he need not say he was tly in accord with the work. Lord Midleton had, he thought, ed the highest heights and given them greater encouragement e work which lay before them. They had done a wise thing in ntling him president, for he took a great interest in the county, o one knew more about the county than Lord Midleton.

e vote of thanks having been carried with acclamation, count Midleton, in response, thought the vote of thanks was ue due to those who had borne the burden and heat of the day— ecretary and officers of the Society—to whom they really owed success achieved. He referred to the fact that more than forty ago he had contributed an article to a periodical on the history antiquities of Surrey, and he then came across a great deal of olklore of the county and many bits of history which were quite o him. Recently an admirable volume—a history of Surrey—een edited by Professor Malden, which threw a most extra- rinary light on what had really taken place in Surrey from the est times down to the present day. He had no idea that the y possessed such a wealth of ancient reminiscences, or that the s of primeval man could be traced so clearly in Surrey. Every

public library in the county, he thought, should possess a copy of the work. It had been, he could assure them, a real labour of love to come there that evening; nothing gave him greater pleasure than to find himself once again in Croydon among many of the descendants of those whom he knew long ago, and who, he had no doubt, would worthily hand down to others the traditions they received from their fathers.

Mr. Whitaker proposed, and Lord Midleton seconded, a vote of thanks to the Mayor for the use of the Town Hall, and the meeting concluded with a vote of thanks to the Libraries Committee for the use of the lecture-room in which to hold the exhibition, proposed by Mr. Maclean, and seconded by Dr. J. M. Hobson.

Patent News.

The following applications for patents were made between March 14th and March 19th, 1904:—

Transparent Photographs.—No. 6395. "To render unmounted photo- graphs transparent for decorative purposes." Kate Osborne.
Printing Frames.—No. 6483. "Improvements in photographic printing frames." William Lawrence Parkinson.
Shutter.—No. 6717. "Automatic shutter for photographic cameras." Complete specification. Otto Peppel and Alfred Lippert.

THOMAS VANDERBILT, photographer, 12, James Street, was sum- moned at the Liverpool Police Court last week for employing three women after 8 p.m. on December 23rd, and also for employing three women on Sunday, December 20th. Mr. P. J. Taylor, for the defence, pleaded that there was a pressure of business at the time, and Mr. Vanderbilt got them to work a little late. The women were well treated by their employer. A fine of 20s. and costs was imposed in each of six informations.

A TAX that Hits Chemists Hard.—Few realise the enormous im- portance of alcohol in the arts. It has been said that a nation's pros- perity can be gauged by the amount of sulphuric acid it consumes. In many industries the amount of work done can be approximately estimated by the spirit duty paid. There are many alcohols known to chemists, but the one of prime importance to manufacturers is that which is more exactly called ethylic alcohol, the product of the fermentation of sugar, and the chief ingredient of all intoxicating liquors; and it is this alcohol which, from the days of Queen Eliza- beth to those of the seventh Edward, has been considered a never- failing source of revenue by successive Chancellors of the Exchequer, until it is to-day taxed at the rate of over 2,000 per cent. "The greatest danger to British industries," wrote Lord George Hamilton a few months ago, "arises from the economical and scientific methods of production which our foreign rivals are introducing in the manu- facture of articles in which we were formerly superior. Anything that tends to raise generally the price of production in this country is injurious to our trade." Exactly! but in the case in point the British Government has made the cost of production to the British manufacturer seven times that of his more fortunate German com- petitor, and no belated attempts at improved technical training nor despairing resort to Protection can make up such leeway. Professor Green has recently stated that the ethylic alcohol used as a solvent in four or five of the principal aniline dyes imported into this country is equal to no less than £90,000 per annum, and the aggregate value may be placed at some £285,000 upon which the Customs could have claimed duty. Such figures are some measure of the disability of manufacturers in this country, competing against manufacturers work- ing in other countries with practically duty-free alcohol. The official reply to manufacturers' complaints is that the Government will allow the use of duty-free alcohol for purposes of research and illustration to recognised bodies formed for the advancement of science or sci- entific education, and for industries of such magnitude and importance as to be of public interest in their bearing upon national trade. But, again, it is obviously idle to allow privileges to research chemists, if similar advantages are not to be given to manufacturers, who would be able to make use of the results of the researches. One might as well teach a child to walk, and then refuse to supply him with boots!—Mr. Wippell Gadd, in "The World's Work" for April.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
2.....	Aberdeen Photographic Assoc.	<i>The Physical Geology of Deeside.</i> Illustrated. M. Alex. Bremner, M.A., B.Sc.
4.....	Burton-on-Trent Photo. Soc. ...	<i>How to Make a Daylight Enlarger.</i> Mr. Glasscock.
4.....	Bowes Pk. and District Ph. Soc.	Competition. Portraiture or Figure Study, &c.
4.....	South London Photo. Society.	Annual General Meeting.
5.....	Rotherham Photo. Society	<i>Principles of Composition and Selection of Subject.</i> Mr. W. E. Tindall.
5.....	Glasgow Southern Photo. Assoc.	<i>Photographic News' Prize Slides.</i> Close of Exhibition.
6.....	Cricklewood Photo. Society....	Lantern Night.
6.....	Everton Camera Club	Members' Lantern Slides.
7.....	Richmond Camera Club	Lantern Night.
7.....	Liverpool Amateur Photo. Assoc.	Open Meeting.
7.....	Watford Photographic Union	Exhibition.
7.....	Woolwich Photo. Society	<i>Colour Sensitive Plates.</i> Mr. E. Human.
7.....	Hull Photographic Society	Annual General Meeting.
7.....	Dundee & E. of Scotland P.A.S.	<i>Elementary Photographic Optics.</i> Mr. John M. Thomson.
7.....	Southport Photo. Society	<i>A Winter's Travel.</i> Illustrated. Mr. J. Noton.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 24TH.—Mr. A. Bedding in the chair. Mr. Teape brought forward examples to show that negatives, chlorised or bromised, could be redeveloped to full density without preliminary exposure to light, the only difference being in the time taken. Mr. Rapson exhibited the results of some experiments in toning, and showed that double toning was caused by the use of too much gold. He advocated the use of silicate of soda, and gave the following formulæ:—

Soda silicate.....	20 grains.
Soda acetate	25 grains.
Gold chloride	$\frac{1}{2}$ grain.
Water	10 ounces.
Soda silicate	20 grains.
Soda formate	8 grains.
Gold chloride	$\frac{1}{2}$ grain.
Water	10 ounces.

Both baths were free from double tones, and worked better when old than when new.

The members all remarked upon the good surface of the prints, which had been squeezed and then mounted all over without any loss of gloss. This Mr. Rapson attributed to the hardening effect of the silicate, and suggested that such prints would be more permanent than the ordinary P.O.P. Mr. Teape, Mr. Becket, and Mr. Brown said that all new baths gave double tones, but that baths previously used did not do so. At the next meeting of the Association Mr. H. W. Bennett will read a paper upon "Some of the Fallacies of Factorial Development."

BURTON-ON-TRENT AND Y.M.C.A. PHOTOGRAPHIC SOCIETY.

A LARGE audience was attracted to the meeting of this society held on Monday, March 21st, 1904, in response to the invitations given, to hear Mr. Fred W. Edwards' lecture on "Radium and Radio-activity." Councillor C. M. Livens presided. The Lecturer, in introducing his subject, said that the mystery and interest of the wonderful product he had to demonstrate was continually increasing, until the theme has become the most absorbing topic of the scientific world. To photographers the subject of radio-activity should strongly appeal, as the discovery was due to the efforts of one of the fraternity. In order to make the subject as clear and simple as possible it would be necessary to divide the lecture into three distinct headings—first, radio-activity, including phosphorescence and the X-rays; secondly, the chemical and physical properties of radium; and lastly, its possibilities and applications. Under the first heading the lecturer gave an explanation of the phenomena of phosphorescence and an account of the discovery of the X-rays, showing them to be a product of electricity, and comparing them with emanations of radium; and, in giving an account of the discovery of radium, a very high tribute was paid to Madame Curie, for the laborious efforts made by her in extracting this most wonderful metal from what had hitherto been looked upon as worthless slag. In considering the chemical and physical properties of radium, the lecturer

stated that it was now regarded as a metal quite independent of all other known element. In colour, shape, and general chemical properties it bears a close resemblance to barium, inasmuch as neither exist very long in a metallic state, and is generally mixed with chlorine which forms radium or barium chloride. Three kinds of rays are given off by radium simultaneously, and it is still a matter of conjecture as to the cause of its activity, but it could not be due to spontaneous combustion or phosphorescence. Several theories had been advanced but each in its turn had been thought infeasible, and the most favoured now was atomic integration. By means of burning different metals in the Bunsen flame it was shown how the problem came to be regarded as a metal, and it was explained that the colour of the flame when radium is burnt differs from that obtained when rays are passed through the flame. An illustration of the conversion of radium into helium brought this section of the lecture to a close. Dealing with the possibilities of radium, Mr. Edwards stated that it superseded the X-rays, and had been applied with some success to the destruction of the germs of cancer and other diseases, but as the quantity available was so small and the subject was only as yet in infancy, it was impossible to foretell what wonders may be wrought in the future, when the cost of production had been brought down as scientists were in a position to make a deeper investigation of this marvellous product and its uses. During the lecture a minute sample of radium was exhibited in an instrument specially devised for the purpose by Sir William Crookes, and evoked the wonder and admiration of the audience. Dr. A. L. Stern, in proposing a vote of thanks to Mr. Edwards for his valuable paper, made a few remarks on the theories regarding the cause of the activity of radium.

CRICKLEWOOD PHOTOGRAPHIC SOCIETY.

At an ordinary meeting of this society, on the 23rd inst., Mr. Wilfrid Emery gave a very interesting and instructive demonstration of "Portraiture by Artificial Light," using to illustrate his lecture, Bayer's Flash-light Powder, Flash-bags, and the Weiss Lamp, with Argento Powder fired behind a screen of white tissue paper.

Mr. Emery took several groups of members of the society, who were developed by Mr. F. Carter, the results being very satisfactory, the negatives showing very soft gradation, being full of detail and good printing density. It was noticed that the smoke from the explosion of Bayer's Flash-light Powder was not so thick, and that it dispersed much quicker than the smoke from the usual magnesium chloride mixtures.

CATFORD AND FOREST HILL PHOTOGRAPHIC SOCIETY.

THE last open lantern evening of the season was held last Wednesday at the Society's headquarters, when Mr. Norman Walters delivered his long-promised lecture on the Continental tour taken last August under his direction, and followed this up by a short description of Belgium and the Ardennes, taking the same route that the members and friends will follow under his leadership later in the season.

Some 150 slides were shown during the evening to probably the largest audience that has ever met in the Society's lecture room.

The next technical meeting is fixed for Monday, April 11th, and the bi-annual conversazione and dance for Wednesday, April 20th, at George's Hall, Catford.

RICHMOND CAMERA CLUB.

MARCH 24TH.—Under the title "Lumbricus, an old developer," an interesting lecture upon the earthworm (*Lumbricus*) was given by Mr. Oetzmann, in which he described the habits and workings of the animals. Mr. Oetzmann explained the work done by worms in pulverising and fertilising the soil, and the great assistance they afford in rendering it suitable for agricultural and gardening operations. The amount of soil worked up and distributed over the surface of fields in the form of worm castings frequently amounts to many tons per acre, and at the same time the burrows aid in the drainage of the ground. The removal of such quantities of soil frequently causes stones, etc., to sink into the ground, and in the course of time to be covered up. In old ruins floors are at times entirely covered by worm castings, and finally lost to sight. Mr. Oetzmann gave an interesting description of the worm itself. The animal is blind but is sensitive to light, probably through its skin; it is deaf but extremely sensitive

trations of the earth; it appears to have a sense of taste, as it makes some selection in the choice of its food, preferring a green to a cabbage leaf, and selecting the green in preference to any dried part of any leaf. Mr. Oetzmann also described their method of growing—the head is first inserted into the soil, the body swelled to the size of the opening produced, and then if the soil is hard it is pushed up and passed through the body, being discharged at the other end in the form of the well-known castings. Worms protect themselves from rain, etc., by closing them up with leaves and matter, which they drag in, and failing vegetable matter, they close the entrance.

HULL PHOTOGRAPHIC SOCIETY.

MR. HOLLINGWORTH, M.R.C.S., gave a most interesting and instructive lecture upon "Alpine Photography" on Thursday last. The Society's room was full, which proved the popularity of both the lecturer and subject.

Mr. Hollingworth made a special study of Switzerland for several years past, photographically and from a lecture point of view, and for the benefit of the members, he expressed the hope that others would take a similar course during their summer vacation, and with the varied results in different directions, quite a number of admirable displays might be given next winter by each, and prove of extreme interest, pleasure, and a delightful reminiscence of perhaps many a summer's hour, with profit to all concerned.

It must be aware of the delicate nature of Swiss scenery, with its verdant mountains against a blue sky and extremely deep shadows, the hundred odd slides produced from the lecturer's negatives, taken in the best manner, were of exceptionally high merit. Each one had been made by the method of quarter-plate roll films. Much time had been spent in developing them, and those present were advised to perform this important step, with care, and to keep down the pyro so as to get contrast and detail. Slow development is the secret of success, far more certain.

It is the best month to make a trip for two reasons, first because it can be done much cheaper, and thus do away with the idea of it being expensive, and secondly, because one has a clear way and not impeded at every turn with visitors, as in the season, which commences in July. It was also recommended that for a photographic excursion one should avoid the party system, but simply start off each day on their own responsibility, leisurely pressing onward, and pictures are secured at almost every turn. The camera must be ever ready for any subjects which would be lost if the focussing camera were set down. All the backward and forward movements employed. There is no need to be little need for a tripod, but a light one would not be a disadvantage if by chance it should be required. The inference is that a hot or hand-stand camera is the ideal for such a mission.

News and Notes.

The opening ceremony of the Northern Photographic Exhibition was held in the Fountain Room of the Walker Art Gallery on Friday evening last (March 25th) in the presence of a large and fashionable gathering. The Chairman (Dr. L. Morgan), in asking the Lord Mayor (Mr. R. Alfred Hampson, J.P.) to perform the opening ceremony, referred to the efforts made by the photographic societies of Liverpool, Manchester, and Leeds in the promotion of the exhibition, the result of which had been a display unexcelled in any part of the country. Referring to the great advance made in pictorial photography in the last few years, Dr. Morgan commented on the high quality of the photographs displayed, and said they made a bold claim that photography itself should rank, if not as a fine art, at any rate as one of the graphic arts, and he thought the time was not far distant when it would be so recognised even by their fellow-artists of the brush as the graving tool. The Lord Mayor, after referring to the co-operative character of the exhibition and mentioning the Liverpool Photographic Society as the oldest in the country, cordially welcomed the exhibition to the city, and congratulated the promoting societies upon its successful issue, and the high character of the work shown, which he said evidenced a great advance. Photography had made giant strides during the last few years, and had not merely advanced in popularity, but as an art, becoming more and more pictorial in its highest forms. He hoped this inaugural exhibition and those to follow it every possible year. Mr. Fred A. Schierwater, president of the Liverpool Photo-

graphic Society, moved, and Mr. E. R. Dibdin seconded, a vote of thanks to the Lord Mayor and Lady Mayoress, and acknowledged the generosity of the Corporation Arts Committee in granting the rooms in the Art Gallery for the exhibition. Subsequently Dr. C. Thurstan Holland and Dr. D. Morgan gave X-ray demonstrations in one of the rooms, and during the evening Mr. L. Rubinstein's orchestra provided music. Refreshments were served in the rooms on the ground floor. The exhibition will remain open until April 9th.

LORD RAYLEIGH on Sir George Stokes.—In the concluding lecture of his course on the life and work of Sir George Stokes, delivered at the Royal Institution on Saturday, Lord Rayleigh began by describing Stokes's work on the conditions of achromatism in lenses. Passing from optical matters, he next considered the paper of 1857, in which Stokes explained why sounds were usually heard badly up-wind. His explanation depended on the fact that the wind tended to be retarded near the ground, and hence blew less strongly at the ground than higher up. The result of this was that a sound-wave travelling against the wind was retarded in velocity, but was not retarded equally at different heights from the ground; its upper parts continually lost on its lower ones, and thus its direction of propagation was tilted upwards, with the result that it passed over the observer placed up-wind from its source, who stood in a sort of sound shadow. A more elaborate memoir dealt with the communication to the air of the sound from a solid vibrating body. A bell, for instance, behaved pretty much as if it were incompressible, neither expanding nor contracting as a whole during vibration, but only expanding and contracting at a series of particular points. These points might be regarded as sources of sound, some positive, some negative, and these being equal ought to compensate each other, no result being produced. But in fact there was incomplete interference of the waves from the different sources, depending on their different situations and distances from the perceptive ear, and what was heard was a residue. The fact that a bell placed in a chamber exhausted of air to such a degree that its sound was faint, though audible, became quite inaudible if hydrogen was admitted into the vacuum, seemed very mysterious till it was explained by Stokes, who saw that the sound-waves were changed in length in the hydrogen, and so also the interference was altered. Lord Rayleigh next described Stokes's method of expressing the conditions in which two or three substances, such as ether, water, and alcohol, could be made to associate in a homogeneous mixture and those in which they separated into two distinct portions. In conclusion, Lord Rayleigh referred to some of Stokes's personal characteristics—his quietness and silentness, which, however, were coupled with a dislike to being alone, the modest appliances with which he worked, his tendency to procrastination, and the earnestness of his religious life. He worked in many subjects, but in optics and hydrodynamics we owed to him fundamental advances, and he scarcely ever failed to lead in the right direction.

PHOTOGRAPHY in Alaska.—You ask me to outline some of the troubles, etc., attendant on taking pictures in Alaska. Troubles are few. Sometimes, writes Mr. F. Callarman, in the "Professional and Amateur Photographer," the water freezes up in the winter; there is very little light here during about five or six months out of the year, and these two things, added to the sometimes more or less emaciated wallet, just about constitutes the sum of our troubles. We have scenery that has no equal; mountains, lakes, rivers, waterfalls, land and sea-scapes, woods, glaciers, and a variety of people, and curious things. Alaska is not, as is supposed by a great many people, a land of continual snow and ice. At Skagway the coldest weather in three years has been 18 degrees below zero, Fahrenheit, and that only for a few hours. The weather is not, as a whole, as cold as that of some of the Northern States. Of course, this does not exactly apply to the interior, where the thermometer goes down to 75 to 80 degrees below zero for days at a time, but there even will be found a time for three or four months in the summer when there is not snow or ice, and, in fact, the weather is at Dawson and other interior points often disagreeably warm in summer, the thermometer reaching 90 to 95 degrees above zero. A word about the Indians here may be of interest. There are many good subjects among them, but nearly all are imbued with a superstitious fear of the camera, and unless taken completely by surprise the great majority of them will not permit their "tookchers" to be taken. However, a piece of silver is in most cases as effectual in banishing their fears as it would be with a whiter and more civilised people, but as this is only to be used as a last resort, I have found the plan by which I captured the basket venders at Kilisnoo quite a help. I turned my camera in the opposite direction from the subjects desired, and after focus was secured on an object about the same distance from me that they were, the plate holder inserted, slide withdrawn, shutter set, and all necessary preparations made, I (with my back still toward them) slowly turned the camera on the tripod until the lens pointed to my breast, then I suddenly stepped to one side and sprang the shutter, giving a half-second exposure before they knew what was up. The silver process would not have been desirable at that time, as there were about 200 Indians present, and bribery would have been too expensive.

THE METRIC SYSTEM.

To the Editors.

Gentlemen,—I should hardly care to make any rejoinder to Mr. Piper's letter in your last issue, but that those who read it may think that what is put forward is unanswerable.

I am sorry that the purpose of my little story is not understood; its object was to show how much the reply to a problem depends on the way in which it is put. I will now, however, try to give another instance, taken, indeed, from Mr. Piper's example. I have taken a half-plate and measured it; of course, it is what is called $6\frac{1}{2}$ by $4\frac{3}{4}$, but I find that it measures as nearly as I can see 16.4 by 12 c.m., and to me the obtaining of its area (196.2 sq. c.m.) is much more easy than the calculation of the area in inches, and it would have been still more difficult if I had taken the dimensions as accurately in English measure as in metric, whether I had used inches, lines, and fractions, or taken refuge in decimals of an inch like Mr. Piper; and here, I may note, that it is not so easy to get a common rule divided into inches and tenths, for all I come across have one-eighths and one-sixteenths.

Next, it is stated that a liter of water weighs 997.7,904 grammes, and that this is at a temperature of 62 deg. F. Now the definition of a liter is that, at 0 deg. C., it contains one kilogram of pure water at its greatest density, and there are good reasons for this definition, which can be found in the discussions of the matter, but which would take up much of your space. Of course, as water, like most other things, expands, the choice of a different temperature leads to a less weight; virtually, the allegation is that the liter does not agree with a definition which is either Mr. Piper's own, or that heretical one which has been invented by the Royal College of Physicians, and repudiated by all men of science, as well as the International Committee.

Mr. Piper says that it is easier to calculate the interest on £67 at $\frac{3}{4}$ per cent, than on 67 dollars or 67 francs. I deny this. But the question is just one of those which I have before called unfair. Two-thirds of £100 is £66 13s. 4d., and the interest on this at the assumed rate is evidently £2 6s. 8d., while that on the small balance of 6s. 8d. is 2½d., making altogether £2 6s. 10½d. Every one knows that some dimensions are more easily expressed in one notation than another; for instance, it is easier to ask for an ounce of tobacco than for its equivalent in metric weight; but then no one (in a country using metric weights) would ask for this equivalent; he would ask for 25 or 30 grammes in all probability, and pay accordingly. Lastly, why should the introduction of metric measures involve a dumping of foreign-made cameras on us, and a consequent injury to our makers' business? I understand that, when price is no object, English-made cameras are preferred on the Continent, and that but for the heavy duties they would be more exported than they are now. Plate-makers make plates of the foreign sizes, and, if camera-makers do not now, they no doubt would make cameras to these sizes, if there were seen to be a demand for them. The law will not prescribe the size of cameras, the question will be solely one of convenience and price. Foreign makers do not find any difficulty in supplying many things made to English weight and measure *when it is worth while*, nor do English engineers and others under the same conditions.—I am, Sir, yours faithfully,

J. F. TENNANT

March 27th, 1904.

THE METROPOLITAN CAMERA CLUB, NEW YORK.

To the Editors.

Gentlemen,—I wish to announce to you the merger of the smaller camera clubs of New York City into an organisation known as the Metropolitan Camera Club of New York, with a membership of 125, and quarters covering 6,000 square feet in a modern building, located in the social centre of the city, equipped with up-to-date apparatus

for all photographic purposes, including a large studio, fitted with new Cooper-Hewitt electrical light for portraiture.

We are also pleased to inform you that announcement will be issued of the first American Photographic Salon at New York City to be held under the auspices of the Metropolitan Camera Club, the Salon Club of America, which will be held on a grand scale, of the foremost American painters having consented to act as jury of selection, and 100 of the most distinguished men in America being numbered among the patrons. We hope for a splendid representation of the work of the great British masters of pictorial photography. The Salon is to be held in December of this year, and announcements will go forward at an early date.—Yours very truly,

CURTIS BELL, President

Metropolitan Camera Club Incorporated of New York,
102-104, West 101st Street.

"PHOTOGRAPHED GHOSTS."

To the Editors.

Gentlemen,—Under the above heading you comment upon photographs exhibited under the auspices of this society, and I should be glad if you will allow me the opportunity to correct one or two misconceptions. First, it was not a "one-man show" of pictures, as evidenced by the fact that it embraced a small collection, none of which either belonged to Mr. Blackwell, nor presented him as a sitter. In one of these Professor Alfred Russell Wallace was the sitter, the spirit, or as it has been termed "ghost," appearing beside his sister. Another represents a table with a photograph standing on it, and in this case two "dim but definite" portraits are to be seen, while others represent French subjects taken by photographers in Paris. The photographers in the case of this collection are not the same as in the case of the majority exhibited by Mr. Blackwell. I state "when works of any kind are thus exhibited in public they run the gauntlet of criticism;" with this I am in entire agreement; acquaintance with the details as to how and under what conditions they were taken, you will admit, is the only way to know whether they have reason to question the bona-fides of anyone concerned with the production. Mr. Blackwell's bona-fides I, personally, cannot impugn, and of the photographer Mr. Blackwell refers to I have also no reason to be suspicious. With regard to the "significance of the promised sittings," I would merely say that at present there is no evidence of the supposition either of collusion between the photographer and the medium, or that the promises were made known, before the photographs were taken, to other than the one to whom they were given. Yours obediently,

PERCY SMYTH, President

Chiswick Spiritualist Society,
300, High Road, Chiswick, W.,
March 28th, 1904.

THE PERMANENCE OF VELOX PRINTS.

To the Editors.

Gentlemen,—We observe from an article which appears on page 6 of your issue of March 18th that you cast some doubt on the permanency of prints produced on Velox papers. This impression, however, is entirely erroneous. We claim that correctly made Velox prints are permanent, and evidence of the truth of this statement may be obtained by examining the prints of theatrical people, which are shown at the entrances of many theatres. Some of these, we know, have been exposed to all kinds of weather for several years, and to-day they retain the same purity in the whites and blacks as on the day they were produced. Furthermore, we may add that numbers of the foremost professional photographers are using Velox paper, and we venture to remark this would not be the case if it had not proved for themselves the undoubted permanence of results.

Trusting you will be able to find space for this explanation in the columns of your esteemed journal, we are, yours faithfully,

JOHN J. GRIFFIN AND SONS, Ltd.

20-26, Sardinia Street, Lincoln's Inn Fields, London, W.C.
March 29th, 1904.

[We gladly insert Messrs. Griffin's explanation, although our reference to the impermanence of "silver" prints was not intended to be a particular application to Velox. With regard to the latter process we have in our own possession prints produced in the year 1896, when Velox was first brought to the notice of British photographers, which are as pure and brilliant as the day on which they were developed. Eds. "B. J. P."]

THE DERBY CONVENTION PROGRAMME.

To the Editors.

Gentlemen,—From a remark in last week's "Jottings," it would appear that our 'good' friend "Cosmos" has not read the Derby programme with his usual care. If he will kindly refer to the *BRITISH JOURNAL OF PHOTOGRAPHY* for March 18 (page 225)—where it is stated in extenso—he will find, Thursday, at 8.30, "A Paper on Demonstration," followed by, etc., etc.; again Friday, at 8.30, "Papers on Demonstrations."

I am pleased to be able to announce that on one of these evenings Thomas R. Dallmeyer will give a paper on "Telephotography." I also promised a paper (subject to be announced) by Mr. Thomas Harding, F.R.P.S., and expect during the next few days to obtain my paper from some equally distinguished source. Let us hope these, coupled with the presidential address, will provide sufficient "solid fare" in our "annual menu" to correct the "picnic" sentiment.—Yours truly,

F. A. BRIDGE,

Hon. Sec. and Treasurer.

East Lodge, Dalston Lane, London, N.E.

TRICHROMATIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—I am in doubt as to whether I am to consider Mr. Eder's letter in your last issue as a whole-hearted compliment or a whole-hearted one, with the full complement of a slap in the face. However, I thank him for his kindly expressions towards myself and my translations. I take it that the reason why no earlier translation appeared is that the paper has never yet been published in any German paper, except the official journal of the Imperial Academy of Sciences of Vienna, before which body it was read. The paper was read in July, 1902, and a brief note about it appeared in one of the German papers about that date, and although I ordered it, I found it impossible to purchase a copy, and, being then "cribbed, cabined, confined" to bed, I did not trouble further. Having occasion early this year to write to Messrs. Penrose, I mentioned this paper, and they immediately offered to get me a copy, and did so. The "B. J." is thus the first photographic journal to publish the paper or a digest of it. Eder himself merely states his conclusions and not his actual experiments in the latest edition of his "Handbuch."

I hope Mr. White and others interested in the subject will grasp the fact, which I have already pointed out, namely, that I have sent them a mere digest of the paper, and that I have suppressed many tables and figures, which, whilst valuable, are useless without the full text. Dr. Eder's coloured chart, which is rendered the more valuable by his spectroscopic analysis of the pigments employed in printing it. Whilst on this subject I might draw attention to the fact that Baron Hübl published a spectroscopic analysis of the chart issued with valuable work on "Trichromatic Photography" in the "Photographische Correspondenz," of 1893, I think, but as I have lent my copy to you I am unable to state definitely the date. Von Hübl's chart is doubtless more valuable even than that of Dr. Eder, because it comes in more colours, or, in other words, whilst Dr. Eder's chart gives the fundamental colours, von Hübl's gives us the intermediate ones, and it might be possible to adjust a plate and filter by Eder's chart, which, when tested on von Hübl's, would prove unsatisfactory. I cannot help thinking that Dr. Eder's chart has more saturated colours than the other—that is, that there is less admixture of white.

—Yours faithfully,

E. J. WALL.

Foot's Cray. March 26th, 1904.

PHOTOGRAPHY IN SOUTH AFRICA.

To the Editors.

Gentlemen,—Having read from time to time in your ever interesting journal queries asked, and opinions offered, on photography in South Africa, I think a little advice from a man on the spot would be acceptable to some of your readers.

The general outlook is not particularly bright at present, and the market, being at such a low ebb, is causing a general depression, which is likely to remain until the importation of Chinese labour becomes an accomplished fact, and the miners are in full swing again. The assistant wanting a berth in South Africa I have no hesitation in telling him to stay where he is, unless he is engaged under an agreement with a first-class firm, of which there are not too many. I may

say here that it is only thoroughly competent men who are wanted in South Africa; "rotters" applying and engaged will soon find themselves in a hole. A case in point. A young fellow from London arrived in Natal four months ago as a printer to a certain firm under a three years' agreement. His work, which was very unsatisfactory, resulted in a three months' notice to quit. He has now to pay back his passage money, £20 odd, off £12 per month salary, and will have to scour the country for a living. To add to his miserable existence, he is down with fever and a doctor attending him. I mention this as a warning.

The salaries paid by the best firms are, of course, according to agreement, but approximately as follows:—A first-class assistant may receive from £15 to £25 per month; a retoucher from £15 to £20 per month (although the retoucher in the firm the writer is with receives £30 per month, which is the highest wage for a retoucher in Natal, if not in South Africa); and a printer (Plat. and P.O.P.) from £12 to £15 per month. To many at home these salaries may look very tempting, but there are not many cribs in the market, and, as I have said before, unless you are with a first-class firm, "the game is not worth the candle."

To the man who is thinking of coming out to start business for himself, my advice would also be to stay where he is, unless he has some knowledge of the country, or is well advised as to place of starting, and even then he would require considerable capital. But circumstances alter cases, and here is one which has come under my notice. An up-to-date young fellow from London arrived here (Maritzburg) six months ago, bringing with him several cases of outfit, with the intention of starting for himself. My governor advised him to try Pretoria, a Dutch centre in the Transvaal, which he accordingly did. A few weeks ago he wrote to the effect that he had built a studio, and had asked the Mayor of that township to open it to the public, with a little ceremony, to which I believe he readily assented. At the time of writing he said: "Although not officially opened, I have plenty of work on hand, and hope to have a good run."

In Natal there are several openings for good men. For instance, in Ladysmith, where I spent a week lately, there is only one tumble-down, sort-of-a-kind of a studio, which has been closed for some time, and many of the better class come specially to Maritzburg to be photographed. There is another good opening at Harrismith, a Dutch centre in the Orange River Colony. I do not know much about Cape Colony; but, if my memory serves me aright, there are more than enough photographers in Cape Town. It is better for the man with limited capital to start in a small rising township, where there are plenty of farmers in the district, than to set up amidst keen competition in the larger towns, where living is high and rents are exorbitant.

That which has surprised me more than anything else since my arrival in the colony is the colossal ignorance displayed by Colonials in their taste photographically. Without doubt this is owing to the want of education in things artistic, and accounts for the little carbon and platinum work which is attempted, and further, I think I am correct in saying there is not a single carbon print turned out in Natal at the present day, and there are only one or two firms in Johannesburg and Pretoria who do anything in carbon. It has been before the public in Durban and Maritzburg, but with little success, necessitating the withdrawal of this most beautiful process. What the public (Colonials and Dutch) want is a good commercial photograph, highly retouched, and still more highly polished. I mention this incidentally to give you an idea of the class of work which is being done, even among the best photographers in the country.

The producer of photographic "freaks" would have a rough time of it, and would possibly finish up by enriching a few yards of soil; but there are a few of the newer Colonists who can appreciate a good sepia plat. on a vellum mount, and I firmly believe there is a fortune awaiting the man who, if he can afford to wait and educate the public, starts in a really good way and sends out artistic work in almost any of the large towns. This remark may seem contradictory to a former, but it applies only to men with big capital. With regard to the prices obtained, they naturally vary, according to the standard of work. The following, however, are a few quotations from our own price list, which are perhaps a little above the average charge:—Cabinets, per dozen, in P.O.P., glossy, 45s.; in matt (P.O.P.), 50s. Imperials, per dozen, in P.O.P., 65s.; in matt (P.O.P.), 75s. Either size, in

carbon or platinum, one-half extra. The above are for one position only; an extra charge of 5s. and 7s. 6d., cabinets and imperials respectively, for each extra position chosen. Carbon and platinum enlargements are, of course, sent home, so we do not get much profit off this line.

In the foregoing I have endeavoured to bring before you briefly what I think is a fairly accurate statement on "Photography in South Africa," and hope at least some part of it will be helpful to intending emigrants. I trust, Gentlemen, I have not encroached too much upon your valuable space, and I thank you in anticipation of insertion.—I am, Gentlemen, yours, etc.,

A SCOTCHMAN IN NATAL.

Pietermaritzburg, Natal, South Africa.
February 4th, 1904.

At the Southwark Police Court, on March 24th, a young woman asked Mr. Paul Taylor for assistance in recovering possession of her mother's photograph, which she said was detained by a certain firm. They had promised to supply her free of cost with a "large crayon enlargement," but they now demanded payment of 15s. 6d., which she could not afford. She was willing to dispense with the copy, but earnestly desired to get back the original. The Magistrate: But did you really believe they were going to do this work for nothing? The Applicant: I did, because the lady canvasser told me so. If it had been a man I might not have believed it. (Laughter.) Inspector Spencer, L Division, said several cases of the kind had been reported to the police. The picture was ostensibly free, but people were required to pay for the frame. The Magistrate: Oh, I know the system, of course. It has often been the subject of adverse comment in the Press. A summons was granted.

The Scottish Photographic Federation.—The Council met at Perth on Saturday, Mr. Coates, President, in the chair. The secretary reported that Muirkirk A.P.A. and Carnoustie A.P.A. had federated since last meeting; two associates were elected. The various features of the yearbook to be issued this season were discussed and approved; these include a gazetteer, local reporters to give information to intending tourists, and a railway insurance of £200. The Salon secretary, Mr. Mackenzie, reported that he expected accounts for the recent Salon would square; this, when it is considered that admission to the Salon was free, was considered very satisfactory. Messrs. Eadie (convener), Horn, Frame, and Milne were elected as the 1905 Salon Committee with full powers. The Salon is to be held in Glasgow, and it was considered that a guarantee fund would be necessary. A start was given to this by each councillor present guaranteeing £2. The Excursion Committee reported progress and the matter was remitted back to them with full powers. The excursion takes place on June 11th, to Calander, when there is expected to be a large attendance. The secretary read a communication he had received from the Portfolio Secretary of the Yorkshire Photographic Union, who very kindly gave full details as to the working of a circulating portfolio. It was agreed to institute such a portfolio in connection with the Federation, and Mr. S. Stewart, Kirkcaldy, was appointed Portfolio Secretary. It was agreed to ask Mr. Arch. Cochrane, one of the Federation judges, to select the prints for inclusion in the portfolio, which will circulate amongst the federated societies next winter. The Secretary was empowered to issue to the associates a monthly magazine dealing with Federation matters. An invitation was received from the Kirkcaldy Society to hold the next Council meeting there; it was agreed that the next meeting be held at Kirkcaldy on May 7th. Mr. Coates entertained the Council to tea.

*** * NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

It may also be obtained from all Booksellers, Photographic Dealers and Railway Bookstalls.

Answers to Correspondents.

- * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO. 24, Wellington-street, Strand, London, W.C.
- * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPH REGISTERED:—

A. Sachs, 8, Manningham Lane, Bradford. Photograph of Opening Ceremony Eastbrook Mission Hall, Bradford.

J. ROBERTSON asks: "Can you kindly recommend me a book on the colouring of photographs? I want to know how to make water colour flow evenly on the shiny surface of P.O.P. prints." I reply: We can recommend "How to Paint Photographs in Oil and Water-Colours," by Alice Baker, price 1s., and No. 44 of the Photo-Miniature Series, "Colouring Photographs," price 6d. Both are obtainable from any bookstall or photo-dealer.

RULED SCREENS.—GLADYS asks: "Will you, please, give me the address of firms that supply the ruled screens for use in halftone work; also about the cost of same (½-plate size)? I am rather perplexed. A friend of mine in the trade gives me the price as between £25 and £40, whilst in a text-book I have I learn they can be obtained at a very moderate cost." I reply: Messrs. Penrose and Co., Farringdon Road, E.C. supply the screens. They will quote you prices if you write to them.

SPECTACLE LENSES.—A. J. PRENTICE writes: "In Sir Wm. Abney's speech on colour photography (page 111, February 7th, 1902), the fourth paragraph he mentions that a 6 in. planoconvex and a 3 in. plano-convex lens will make a good combination. I should like to get some of these lenses, but do not know what to ask for at an optician's. Do they speak of spectacle lenses as being so many inches focus, or do they speak of them as being lens No.?" Merely ask for lenses of the focus desired, and any optician will supply them.

STUDIO QUERIES.—H. COLLINS says: "Will you oblige by answering the following? Having erected a studio with a direct north light, all glass in the north except 4 feet blocked at sitting end, inside covered with match-boards sized and varnished—(1) What colour blinds would you suggest for same? (2) Would an ½-plate R.R. lens working at f8 be quick enough for portraits in studio? (3) What colour should a balustrade and pedestal be painted? (4) Could you give me address of makers of cardboard dark slides? Should like to say have only had experience with out-door photographing, and any advice will be gratefully received." I reply: (1) Either pale green or blue will be suitable. (2) The lens can be used, but it will require about four times the exposure that a portrait lens would do. (3) The dark stone colour. (4) The slides may be had through any of the dealers.

* * OWING to the necessity of our going to press one day earlier this week, a number of answers to correspondents are unavoidably held over.

BRIGHTON intends to follow the lead of other large towns. The Fine Arts Committee of the Corporation has resolved to hold an invitation exhibition of pictorial photographs in the new Corporation Art Galleries in April, and May, 1905. The Committee has secured the co-operation of the Hove Camera Club.

EX CATHEDRA.

Amendment the Patent Laws. This is a topic of perennial interest, and the grievances—legitimate grievances—in connection with it that have been brought before the scientific world, and, need, the public generally, would fill countless volumes. Theoretically perfect patent would be one that, once granted, would entitle its holder to complete protection without the possibility of its being overthrown by a verdict in an action at law. We can see no possibility of its being anything more than a Utopian dream. Quite apart from the possibility, after, even, a most rigid search of patent records by trained experts, of an injustice being knowingly done to some forgotten inventor, the labour involved would be enormous, and the grumbling that is heard loudly in some quarters as to the cost of taking out a patent, would be increased tenfold if the cost of such searches were to be paid by the would-be patentee. There is an improvement in the present English Patent Law over that in existence at a later period than the middle of the last century—a period when a patent could be taken out for anything, new or old, and, if valuable, usually had to be fought for afterwards. There is now to be prima facie evidence of novelty, though the strictness of search before granting the patent is not so great in this country as in Germany, for instance. These, though grave, may be termed incidental troubles. A grievance that ought to be remedied at once does exist, and we were pleased to see that the annual meeting of the Association of Chambers of Commerce, recently held, devoted their attention to the subject. It can be briefly

described as the "dumping" of foreign patents in this country, and the resolution passed at the meeting was that "this association, while welcoming the instalment of reform secured by the Patent Law Amendment Act of 1902, is of opinion that further amendment is needed to ensure the forfeiture of all foreign-owned patents for inventions and designs workable in this country which are not so worked within a reasonable limit of time."

* * *

The Metric System. At the same meeting a topic of a more disputatious nature was handled—the compulsory use of metric weights and measures throughout the United Kingdom—yet it was resolved that the Government should be urged to grant early facilities for the passage of the Bill for this compulsory adoption. There are one or two facts in connection with this matter which, without initiating a polemic, may be here referred to. The first is, that it was only so recently as 1878 that an Act of Parliament was passed which rendered all old local or customary weights and measures illegal. Secondly, there is a great tendency to confuse scientifically accurate weighing and measuring and that in commercial or popular use. We should very much like to ask what photographer has in his possession measuring glasses, for example, correct to one per cent., or, having them, is, in their ordinary use, careful to, say, two or three per cent. of a required measure? That means, if he has to measure, say, half an ounce of a liquid, is he certain to 5 or 7 minims that he has poured out the correct quantity, or if ten ounces have to be measured out, can he assert that he has not two or three drachms above or below that bulk? In this connection we will quote a pregnant sentence from Professor Perry's six lectures on practical mathematics, delivered to an audience of working men at Jermyn Street: "When calculating from observed quantities it is dishonest to use more figures than we are certain of." Yet how often do we find in photographic formulæ fractions of a minim, or of a grain, when we know quite well such nicety of measurement never took place in practice!

* * *

The N-rays Mystery. Sir William Crookes is responsible for the "mystery of radium" expression, but the rays that M. Blondlot has described are wrapt in a far deeper mystery than ever attached to the radium rays. Only a few weeks ago that expert scientist not only described how easy to produce were the rays, but he actually measured their refractive indices through certain media, and also their wave-lengths, and on March 14th, at the Paris Academy of Sciences, M. Bayard gave

the extent of the rotary power of solutions of sugar, tartaric acid, and turpentine for eight groups of rays. Yet English and American observers, so far from being able to examine the N-rays with such nicety and precision as this, are actually unable to see them at all. Nearly a page of "Nature" was recently occupied by a letter dated March 10th, over the signature of C. C. Schenck, of the McGill University, in which he plainly states that, though he has been endeavouring for months past to repeat M. Blondlot's experiments, he can get no results that can be justly attributed to other than ordinary known causes. With regard to the measurement of indices of refraction and wave-lengths, he shows mathematically that under the conditions described by M. Blondlot it would hardly be possible to detect the existence of separate beams at all. Then, again, as to experimenting in the same direction with a diffraction grating, he says that Blondlot was apparently able, with regard to "a radiation so feeble that no observer outside of France has been able to see at all," to split up a divergent pencil of N-rays coming through a slit 5 mm. wide into eight divergent homogeneous beams by passing it through a prism, then to take only as much of one single beam as would pass through a second slit 1.5 mm. wide (having perhaps 1-50th the intensity of the original beam), and after allowing this small fraction of the whole beam to fall on a grating, to detect the existence of, and to measure up accurately, a central image and no less than twenty diffracted images the intensity of each of which must have been considerably less than 1-1,000th of the original beam! We can only say, "Magna est veritas et prevalebit."

* * *

Punch Artists.

In Mr. Layard's life of the celebrated "Punch" artist, Charles Keene—a book of which only 250 copies were printed for subscribers—occurs an interesting account of the manner in which photography first threatened the business of the wood engraver in those pictures which week by week for some years have been a pleasure to thousands. Charles Keene, like the other artists on that periodical, made his sketches direct on the wood block up to the year 1872, when the method was adopted of making the drawing on paper or cardboard, photographing it, and then transferring the film to the block. Sir John Tenniel, we learn, continued for a long time afterwards to draw on the wood direct, a circumstance that we must regret, because the originals were destroyed as drawings in the work of engraving them. Up to the time that this book was published (1892) the process block seems not to have been used at all in the pages of "Punch"—at least, no mention is made of zinc, or half-tone. We know now, that the wood block has been abandoned in favour of both processes, examples of which are constantly being published. It is a pity that the half-tone block was not used earlier, for the reproduction of Charles Keene's drawings require something more than mere "line." We learn that he to a large extent manufactured his own inks, and made them of various shades, so as to get tones into his pictures otherwise than by the combination of lines. Then, to quote from the volume in question, "in addition to his use of home-made inks, Keene worked largely with small pieces of wood lashed on to penholders, manufactured in lieu of pens by himself. With these he was able to put exquisitely soft touches and obtain delicate shades of expression, which were the despair of the most finished wood engravers." Beyond these idiosyncrasies, he objected altogether to drawing paper and Bristol board, preferring a rough bit of note-paper, which he liked all the better if it were coloured by age. In one picture, representing King

James in the throes of sea sickness, he selected a paper of a delicate green tint, which much enhanced the effect of the drawing. With more modern methods of reproduction the facsimile drawings which illustrate this handsome volume give all the niceties and peculiarities of Keene's method, and most of them are printed on toned paper, so as to heighten their effect. The volume is interesting in other ways, and is well worthy of perusal by photographers and pen artists alike.

* * *

Fraud in Connection with Photography.

A few weeks ago we called attention to a fraud that is being systematically practised on the public by unscrupulous photographers who, while charging for platinum pictures at about double, or more, the price of their silver prints, supply silver prints of the bromide and gaslight type for veritable platinum pictures. We are pleased to see from a letter which we published a fortnight ago, that the Platinotype Company are considering the question of putting a stop to this fraud. The fraud by "Tanqueray," now carried on by him in Paris, is being imitated in England, as well as in Scotland, as will be seen by reports that have appeared in our pages. Last week we alluded to an application made at the Southwark Police Court by a young woman, for the magistrate's assistance for the recovery of her mother's portrait. She said that a certain firm, through a lady canvasser, had promised to supply her free of cost with a "large crayon enlargement," but they now demanded 15s. 6d., which she could not afford to pay, and they would not give up the original picture. Of course, it is the old tale of expecting "something for nothing." The magistrate asked the applicant if she really believed they were going to do the work for nothing. The reply was that she did, because the lady canvasser told her so, and that if it had been a man she said she might not have believed it. The magistrate granted a summons. Male touts—or canvassers—in this class of trade are common enough in the suburbs, but this is the first time of a "lady" canvasser being employed in this kind of business that has come under our notice. Here is a fraud, practised in the suburbs, that was brought to our notice some time ago, and it was chiefly practised on servant girls. A tout called, showing cabinet portrait and enlargements, which might be had for so much and paid by weekly instalments. But the sittings were to be given at some distant part of London, and when the inconvenience of this was pointed out, the dupe was told that after a certain number of instalments had been paid, an order would be issued for the sitting to be given by one of the leading photographers in the neighbourhood. When the instalments were duly paid, and the order given, the dupes went for the sittings, and were, of course, told by the photographer that he knew nothing of the matter, and explained that they had been defrauded. He brought the matter to the notice of Scotland Yard, and was visited by one of the officials, but as he was not the party defrauded, he could not take any action in the matter. By this time the party had cleared out of the neighbourhood, probably to work some other district in the same way.

* * *

A New Pharmacy Bill.

A new Pharmacy Bill is to be introduced in the House of Commons, and it is understood that in the drafting of it the Government have utilised some of the clauses of the Pharmaceutical Society's Bill which was a short time ago introduced by Mr. Lough, besides carrying into effect some of the recommendations of the Departmental Committee of the Privy Council on Poisons, which issued

report more than a year ago. The Government Bill is not yet printed, but the recommendations made by the Departmental Committee, if carried into effect, would place considerable restrictions on the sale of poisons that are used for industrial purposes, and probably in photography. There are at present only two poisons that are used by photographers on which the sale is restricted in England, namely, bichloride of mercury and cyanide of potassium; these can only be purchased, except in wholesale quantities, from pharmaceutical chemists. There are several other chemicals that are used in photography which are of a poisonous nature—pyrogallie acid and some of the newer developing agents, for example. But it is to be hoped that these will not be included in the projected Bill. If they are, they will probably only be vendible by pharmaceutical chemists, when photographers will possibly have to pay more for them than they at present do when purchasing of their dealer. Since the suicide of Whitaker Wright by cyanide of potassium there have been several suicides by the same poison; yet, although its sale is restricted to pharmaceutical chemists, it has not prevented the suicides. The Bill promoted by the Pharmaceutical Society, and introduced into the House by Mr. Lough, is mainly aimed at the "stores," carried on by limited companies. It is proposed that "no company, or firm, or body of persons shall keep open shop for the retailing, dispensing, or compounding of poisons or of medical prescriptions, unless each shop shall be bona-fide conducted by a registered person; or to permit or suffer in such shop any poison to be retailed or any medical prescription to be dispensed, or compounded otherwise by or under the supervision of a registered person; also, it shall be unlawful for any person, or any company, firm, co-partnership, or body of persons to keep any shop, unless the address of the shop shall have been registered upon the register of shops to be kept under this Act, and the name and address of such registered person to be in the bona-fide conduct of the person who shall have been registered, etc." This Bill, if passed, would give the public the protection that their prescriptions would be dispensed by, or under the responsibility of, a certified chemist, and at the same time to an extent protect the pharmaceutical chemists from the cutting prices of the "stores." If this Bill passes it will in no way affect photographers. But in the case of the Government Bill it may be different. However, neither Bill has yet passed, and we understand that Mr. Dixon-Learland has given notice of his intention to move the rejection of the Bill on its second reading.

* * *

Cinematograph Patents. A good deal of correspondence with reference to the Patent Laws has recently been published in the "Society of Arts Journal," and we may hope that it will attract the attention of those who are able to bring influence to bear upon the powers that be. We dealt with the matter of Patent Law reform quite recently, and have no intention of returning just now to the same subject. What particularly aroused our interest in looking through the correspondence just referred to, was the letter from Mr. Friesse-Green, who is not only able to show by his own unfortunate experience how the present laws affect the poor inventor, but gives us an interesting peep into the early history of the cinematograph. He tells us that he began working upon this instrument twenty years ago—long before it could be made commercially, the difficulty being "that celluloid was not made in long lengths, and, therefore, could not be used for cinematograph films." We confess that we are unable to follow Mr. Green's statement, for there is no difficulty in joining celluloid, and, as a matter of fact, some of the most successful "trick" films have necessarily a great

number of junctions. Any one who has handled these celluloid ribbons will know that it is both easy and simple to make a strong joint by means of amyl acetate. This, however, may be regarded as a digression. Mr. Green goes on to say that he first showed the invention at a meeting of the Photographic Society at Pall Mall in 1885, and that it was patented four years later. The celluloid, he tells us, was not sufficiently transparent, it was very expensive, and it was not until 1893 or 1894 that a non-shrinkable celluloid photographic film, transparent enough to enable pictures to be projected upon a screen, was produced commercially. He took out further patents, and these, with those of 1889 and 1893, he considers to be the master patents on this invention. Parents are naturally apt to think too highly of their own children, and to forget that there are other youngsters in the world worthy of commendation. Surely Mr. Green has heard of a little instrument which was brought out, and we believe patented, several years before 1885. We refer to Beale's choreutoscope, a little contrivance which would fit the ordinary lantern stage, and which exhibited on the screen a dancing figure—hence its uncouth name. There is no doubt at all that the germ of the modern cinematograph machine is found in this primitive apparatus. By simple means the figures were made to pass in succession behind the lens—with a pause between each apparition, while a shutter cut off the light between the successive appearances. Still earlier than this was the Phenakistiscope contrived, curiously enough by a blind man, Plateau, of Ghent. This was arranged for the oxy-hydrogen light of Duboscq, and a very complicated affair it was. In this instrument the components of the picture were painted upon a revolving glass disc. The first photographic contribution to cinematography was, of course, found in the studies of animal movements by Muybridge, of California, and he himself used a rough appliance for throwing those movements upon a screen. Thus we see that many minds were at work upon the idea from which afterwards, in the hands of Edison, Birt Acres, Friesse Green, and others, was gradually evolved the cinematograph. Like many other inventions, the credit must not be given to one man, but to many. The two instruments which we have named were quite familiar to visitors to the Old Polytechnic institution twenty-five years ago. And we are able to show, by a quotation from a volume compiled by Professor Pepper, of ghost fame, who was for many years the guiding genius of the place, that the book form of cinematograph, now so common in the penny-in-the-slot machines, was also well-known. He writes of "the penny book now sold in the streets. The little pages have printed on them a series of devices representing any ordinary act of motion, such as a see-saw, and by rapidly passing the pages over the thumb with the first finger the effect of apparent movement is secured, as it would be with Plateau's apparatus, the Zoetrope, or Wheatstone's disc, with the checking and arresting mechanism."

We have received the prospectus of a photographic exhibition on a large scale, which is being organised under the auspices of the Corporation of Glasgow. The Museums and Art Galleries Committee have the matter in hand, and the exhibition will be held in Campbell Gallery, Glasgow, from June to October next. No charges will be made to exhibitors, and the exhibition will be open free to visitors. In addition to bearing all expense connected with the undertaking, the sum of £20 has been allocated by the Corporation for prizes to competing amateurs. That amount will be at the disposal of the appointed judges, to be awarded to the works which in their opinion are most meritorious, irrespective of class. All information and entry forms, etc., can be obtained from the Secretary, Art Gallery and Museum, Kelvingrove, Glasgow.

MENTAL EQUIPMENT.

THE photographic season opens with the buds. As in the days of Chaucer, "the showers sweet and strengthening sun of April" bring about the same inherent desire to get out into the open air, and roam, as they did in the case of the Canterbury Pilgrims. A pity there was no photographer near—cinematographic, by preference—to preserve these immortal worthies for our benefit as they came out of the "Tabard" yard, starting upon their anything but ascetic pilgrimage to the tomb of the pious à Becket. But, to come back to the photographic season of 1904, about to commence, it means the careful examination and furbishing up of all material equipment, cameras, lenses, slides, shutters, stands, and so forth, that have been laid by with more or less care during the past winter months. Might it not be well to attend to and furbish up the mental equipment as well? As a matter of fact, how many photographers are there who give any deliberate heed to mental equipment? The camera has been carefully dusted, the lenses polished with soft silk, and the slides draw out smoothly to their full. But has the photographic mind been dusted, are its slides working freely, and has its eye been polished? Probably not, in the majority of cases, and a start will be made with the dusty, orthodox ideas of last season, and the season before. We do not mean to say that the mind is inactive, but that it is not active beyond the necessary point for carrying out the demand made upon it by the technical power of working. It is possible with great advantage to go beyond this stage. It is advisable to do so, and to enlarge mental equipment. Many who have taken up photography have dropped it after a few seasons, owing to the uniform mechanical character of the results gained. It does not satisfy their souls. It is a pity, and a heavy loss to the ranks of photography, for the very fact of their being dissatisfied for this reason is inferential proof that they are good men with individuality and artistic instincts. If that individuality and those instincts could find practical satisfactory expression, their possessors would probably be found well to the front. Is it possible to do so in the fields of photography? We believe that it is. Many and varied are those fields. There is that of the snap-shooter on the crowded beach or sunny pier; of the landscape worker seeking after the due apportionment in his picture of foreground, middle and extreme distances; of the interview illustrator of the weekly pictorial; of the commercial cataloguer; and of the studio professional carefully choosing the most interesting—or the least disagreeable—side or pose of his sitter, and afterwards polishing up the result laboriously at the retouching desk. They are all fair fields, and the labourers in them are good men and honest, fully deserving of their reward. May they—the rewards—never grow less. All such workers must, of course, be regarded as mentally equipped, after a fashion. But it is not equipment of the highest order, because it is exercised within but very narrow bounds, and is largely a question of formulae, customs, traditions, and text books. No particular appeal is made to the individuality, and possibly special powers of the worker. Where such exist they do not find expression. There are higher regions in which this last is possible, and where the results, as representing something of a man's own self, would be regarded in a very different light to the usual ones. Once in touch with this type of work there is little fear that interest will flag, or that photography will not be a large gainer. It is impossible to indicate fully the means by which these higher fields may be reached. The attempt will only be made to point out one path. As they are "higher" fields, it means a climb to begin with. It is

difficult to get to them. But this in itself would not prove a bar, provided there were a conviction that power was being exercised in the best way. A true man does not object to hard climbing, if only he feels that he is on the right path. It is a "path," too, and the higher paths of the mountain-side are ill-defined, compared with the travelled roads along the valley flats. To follow the simile, a man under such circumstances must have a broad instinct for locality, must have the *feel*, as it were, of where he wants to go. In the chief place, then, what would he like to see in his final print? He cannot very well express it himself, for, as a rule, it is vague. It certainly has not the sharply defined detail and the straight bounding lines of the print from the half-plate negative, even though that negative be photographically perfect. There are no lines that he can remember in the something that appeals to him sometimes as best worth picturing, nor much detail either. The charm of the diffused, which cannot be contained within a square negative, must tell against the photographic, eminently a sharp, four-sided art. But need we hold to the orthodox? We can vignette, it is true; but the bounds of the ordinary vignette, as a rule, are but little better than squareness. Oftentimes they are worse, in their suggestion of the means and effort to reduce squareness. What is desired is oftentimes contained in a negative, if we could only eliminate that which we do not want. But as the something to be eliminated may be, as often as not, away from the borders, cut off by the vignetting form, this method of elimination is impracticable. Why not adopt that used by block makers, by which the undesirable is blocked out of the picture? It is by using Chinese white as a vignetting or concealing agent, and taking a fresh negative from the print worked upon. Very little practice will enable one to do the work. It is not pure photography, but the means are immaterial if the result desired is gained. It seems rather foolish to regard the power of a special tool rather than the result aimed for. A tool should be used as far as possible; but surely it should not be allowed to cramp the accomplishment of purpose, when there are others available, though of a different order. Equally foolish it is to try and make a tool do work for which it is unsuited. We have seen too much of it in the "twilight" and "impressionist" rubbish turned out by lenses out of focus, and so forth.

A plan of work advocated, and one by means of which fuller individuality can be expressed, is this. Select something that you personally would very much like, and take a photograph of it under the best possible technical conditions towards gaining a perfect negative. The fact that you will be able to block out in the final picture anything you do not care for will give you a better chance in this, for you will be able to choose your point of view independently of any otherwise undesirable detail, which will probably be an aid in better gaining the salient feature. Block out of the print with Chinese white all you do not care for, and at the same time strengthen wherever you can with a soft lead. From this worked-up print take a fresh negative, which will give you all you originally desired. If an enlargement be desired, let the second negative be a quarter plate of the sharpest character. Success will not come with the first or second effort; but such possibilities will be opened out as will make perseverance towards success a pleasure. A perfect negative pure and simple is a very rare thing. The writer, at any rate, out of many hundred efforts could certainly not pick out half a dozen. But the peculiar part of it is that even those admittedly few perfect negatives, of scenes carefully selected as the most pleasing and gratifying to his feelings, are not regarded as anything equal to

portions selected, and treated as advocated above, out of negatives which, as wholes, were decidedly faulty.

The main point of the contention is that, as far as the photographer is concerned, he will use his brains more fully in selecting and working, and be able to turn out a picture that appeals specially to him. The result will benefit photography in making it clear that it is a medium by which brains can express their power in a general and artistic, as well as in the admitted technical and mechanical way.

SOME NOTES ON THREE-COLOUR WORK.

READING through the translation of Dr. Eder's notes on three-colour work, recently appearing in the *BRITISH JOURNAL OF PHOTOGRAPHY*, has led me to write the following short article. It may be of use, and will, at any rate, be of interest to those concerned in colour matters who are following the work translated.

Preference is given by many to the use of separate plates for the three exposures in colour photography, especially as the green-sensitive plate can be made so rapid by using a bath containing free silver nitrate and the requisite dye. But the dry plate is entirely different from a collodion emulsion, and

of these dyes which fall into the hands of different experimenters vary to a considerable extent, and, therefore, we must not always expect to get such a result as Dr. Eder claims to have obtained. But it is a remarkable thing that in each instance, as far as personal experience goes, the results should not have been anything like so good as those stated to be produced by these various authorities.

As an example, the sensitising bath with Wool-black 4 B given in the translation does not give a remarkably good result, and even in a stronger form the plates bathed with it leave very much to be desired. The following bath was used for bathing, and is distinctly preferable to the course suggested by Dr. Eder:—

Soak the plate for three minutes in

Wool-black 4 B (1 per cent. alc. solu.)	15 cc.
Water	100 cc.
Ammonia (concentrated)	3 cc.

Dry the plates in darkness.

The dry plates were exposed in a diffraction-grating spectroscopic camera, and in Fig. 1 we see the results of two exposures (A sixty seconds, B thirty seconds) to the spectrum of incandescent gas; glycine development. Fig. 2 shows a twenty seconds' exposure developed with metol-hydroquinone.* Both plates were very foggy.

While it is evident from these results that the sensitiveness imparted to the plate extends to the whole visible spectrum, it is at the same time obvious that the red-sensitiveness is only a fraction of that which would be conferred by cyanin blue, orthochrome T., etc. My results with Nigrosine, Dianil-black, Titan-scarlet, Pluto-black, and other purple-black dyes gave

Fig. 1.

Whilst the latter can be sensitised for any one portion of the spectrum with comparative ease, the dry plate should undoubtedly be panchromatic.

A great deal of confusion was at one time caused in my experimental work by allowing the writings of other colour workers to be the "guide," as it was found in nearly every instance that the resulting sensitising action of a dye was widely different from the action stated by certain "authorities." At the present time what is very greatly needed is the publication of thoroughly practical notes on three-colour work, and I should like to see an account of the experiments carried out by some well-known worker with the dyes recommended by some authority such as, for example, Dr. Eder.

On page 252 of the issue of March 25th, 1904, of the *BRITISH JOURNAL*, the mention of Wool-black 4 B is to be noted as being an excellent sensitiser for the blue-printing plate.* In the first part of Dr. Eder's recent work on gelatine-emulsions mentions the use of Wool-black 4 B, Pluto-black, Dianil-black, Nigrosine, and many other dyes, which are suggested as other red-sensitisers or sensitisers for the whole spectrum. Now, it is of course quite possible—and likely—that the samples

Fig. 2.

similar results, silver nitrate being necessary in some cases to get a passable sensibility.

Baron Hübl, in his "Die Dreifarbenphotographie," gives Dr. Miethe's formula for a bathed plate, and plates bathed with this solution have a really remarkable and genuine panchromatic sensitiveness imparted to them. The following is the method of preparing the formula, which, though long and tedious, nevertheless well repays the trouble taken:—

Make three solutions as follows:

A. Glycin red	1 gm. or part.
Alcohol	500 cc. or parts.
B. Chinolin red	1 gm. or part.
Alcohol	500 cc. or parts.
C. Cyanin blue	1 gm. or part.
Alcohol	2,000 cc. or parts.

Mix 5 parts of A with 5 parts of B, add 12 parts of alcohol and 25 parts of water. Allow to stand for an hour, then add 1 part of C, and filter. When filtered add 25 parts of alcohol and 50 parts of water. Then add another 1 part of C, with 1.25 part strong ammonia. Soak the plates for two minutes, then dry them in darkness.

* By a slip of the pen, Mr. Wall has called this the red printing plate.

* The red end of the spectrum is on the left-hand side.

It should be mentioned in conclusion that the plates bathed with Wool-black 4 B when exposed through the red filter to the spectrum gave a good result, the C, B, and A lines being equally densely represented; but they offered no advantages over any good make of ready-sensitised panchromatic plates, and when not exposed through a filter are, to my mind, of little value.

T. THORNE BAKER, F.C.S.

THE OPPOSITION TO PHARMACY REFORM.

THERE has been much excitement and commotion in the pharmaceutical dovecots during the past two or three weeks anent the introduction, by Mr. Lough, the indefatigable Member of Parliament for Islington, West, into the House of the resuscitated Pharmacy Bill. The later statement by Mr. Balfour with regard to a promised "Sale of Poisons" Bill is answerable also for some awakened interest in the probable action of the Commons in reference to these matters.

So far as concerns the Pharmacy Bill, it is pretty clear that this Bill requires only a fair field and a clear course in order to receive favourable consideration. The Bill has received the general approval and support of the bulk of the Members of the House of Commons; with the exception of such Members as have a direct money interest in the opposite direction, its provisions have invariably commended themselves to disinterested parties. But a private Bill which is blocked may be said to be, under existing circumstances, as good as done for.

The opposition is to an extent twofold. To Mr. Alexander Cross, M.P. (member of a firm recently fined for illegal sale of a scheduled poison), anything proposed by the Pharmaceutical Society is at once anathema! The opposition of such Members as Messrs. Bailey and Batty Langley is directed mainly against Clause 7 (the qualified directors' clause), though Clause 11 (registration of shops and managers) is also considered obnoxious. Then Mr. George Harwood, M.P. for Bolton, has blocked the Bill under the impression, we are told, that it would affect the sale of Cockle's pills!

The main objects of the Bill are to put companies on the same footing as individuals, i.e., what is illegal for the individual should also be illegal for a number of individuals; secondly, to prevent the multiplication of branch shops either by individuals or companies except under qualified personal management; and, thirdly, to prevent the formation of bogus companies by compelling all the directors to be qualified chemists. With regard to the first proposition, the injustice to the properly qualified and duly certificated individual by allowing seven unqualified individuals in a corporate capacity to assume his functions and title is, of course, quite clear. It is true equally, of course, that each individual member of this seven would bring himself under the law if he or she, being unqualified, by chance made a sale of a scheduled poison to the public, but in their corporate capacity they are apparently unassailable; it is the paid and unqualified seller, frequently a young fellow with a small salary, who has to bear the brunt of the pharmaceutical attack.

The second proposition is also desirable and a move in the right direction; but with regard to the third we think it would be sufficient to provide for a bare majority of qualified men on the directorate. Two out of three, or three out of five, would be, in the present condition of affairs, a fair and reasonable stipulation. This would be practically a death-blow to the bogus company, and would do no shadow of harm to the big, and for the most part well-managed, companies, such as Boots and Taylors. The arguments of some of the opponents of the Bill are extremely fatuous. We read, for example, that Mr. A. Guess, of Leeds, addressed an audience of interested

persons at a meeting held recently in Manchester. After a few remarks on the subject of "Brains," this gentleman informed his hearers that "he was apprenticed to the trade of a chemist and druggist, and his father paid a £100 premium; but his master, although a pharmaceutical chemist, neglected to teach him the theory to enable him to go through the minor examination of the Pharmaceutical Society." This is an argument in favour of universal mediocrity. What is the use of any test of efficiency under such circumstances? Surely the unfortunate and unqualified sections in the professions of law and medicine have an equal right. The prospect of such a phalanx of interesting and guileless persons claiming their certificates on the ground, amongst others, of mental incapacity, is decidedly amusing.

Examinations are for the most part more difficult and stringent than they were some years ago; but on the other hand facilities are much greater in the direction of tuition in the various branches of science and art. In the sixties and seventies premiums were the rule in the drug trade, the master was usually a man who was on the register by virtue only of having been in business prior to the passing of the Act, and was not able, even if willing, to impart any theoretical knowledge. There were few classes of any sort open to the apprentice in those early years, and hours were longer, but he kept his nose to the grindstone, and pulled through *then*, as anyone else may *now*, by virtue of persistent study and hard work. At least that was our own experience.

The argument, also, that with the advent of companies and stores has come an era of cheap drugs and chemicals, has really nothing to do with the case, and, if it had, is one which will not bear a hard test. The biggest of the companies have not, as a matter of common knowledge, a low rate, and of universal application; compare prices in general in cities such as Liverpool, Sheffield, Manchester, Leicester, Nottingham, Derby, and Birmingham, to say nothing of the Metropolis, and we very easily discover that prices may be very variable. Dividends must be paid, and if directors cannot get them out of Birmingham, they must make the Sheffielder, or the Manchester man, or the Liverpoolian pay.

The prospects of the Bill are far from rosy, as will be seen. Its propositions are such as most Members approve; taken individually they have little to say against the reform. The great difficulty appears to be to bring the matter to debate and vote.

The "Sale of Poisons" Bill foreshadowed by Mr. Balfour will be awaited with interest; until it is definitely seen what is in view we cannot venture an opinion, except to the effect that any "widening of the gate" is improbable.

A PHARMACIST.

THE BRITISH PAVILION AT ST. LOUIS.

COLONEL C. M. WATSON, Secretary of the Royal Commission on the St. Louis Exhibition, and Commissioner-General, writes a correspondent of the "Times," has just taken possession of his offices in the pavilion erected on the World's Fair grounds by the British Government. This is a reproduction and adaptation of Wren's Orangery at Kensington Palace. It has been erected from designs made by a British architect, and the work of erection has been carried through by the well-known London contractors, Messrs. George Trollope and Sons. It is understood that the cost has been something over £20,000. As usual in all exhibitions, the British Commissioners have not been content to put up a temporary building in plaster or, as it is known technically, staff, but have made it as solid as if it were to stand the test of time.

The finishings and furnishings of the interior of the building are in keeping with the character of the apartments represented. The banquet hall, with fine panelling, is a reproduction of the Orangery at Kensington Palace. The plaster ceiling is enriched with the Royal arms and festooned mouldings of fruit and flowers, the work of the contractors. The furniture of this room, by the same firm, comprises fine reproductions of historical examples of the Queen Anne period. The old console tables formed part of the collection at Merstham House (Lord Hylton). The chairs are reproduced from the originals in the possession of the Earl of Westmorland and others. The brass chandeliers are patterned upon fine old examples. Next to the banquet hall is a fine suite of rooms designed in old English styles.

The Elizabethan room has an ornamental ceiling copied from the breakfast room of Holland House, to the designing and production of which some of the best artists of the day contributed. The chimney-piece, panelling, and plaster frieze are taken from well-known examples, such as Bromley Palace, Knole Park, Crewe Hall, and others. The furniture belongs to the same period, the small cabinet being a copy of one dated 1611, formerly belonging to Archbishop Sharp. The two large arm-chairs are also examples of the period. In the centre is a copy of a fine old Elizabethan table, formerly in the exhibitor's possession. The arm-chair and settee are adapted from models of the famous collection of Elizabethan furniture of Knole Park, but the seat of Lord Sackville, while the high-backed arm-chair and stool are exact reproductions from the same collection, in which are also drawn the designs for the chandeliers. The room was formerly in the collection of the late Earl of Mount at Cowdray, who also possessed the originals of the chairs covered in old embroidery.

The Georgian Room, with white carved panelling and mahogany doors, is a fine specimen of English work of the period, reproduced from an old house at Epsom. The furniture consists of beautiful examples of the period with a few reproductions of old pieces, formerly in the exhibitor's possession. Wall lights are copies of old ones. The Adams Room, with enriched plaster ceiling, frieze, and doorways, is taken from examples designed by Robert and James Adams in the latter part of the eighteenth century. The furniture in this room is in the manner of Sheraton, and comprises many actual examples of the period. The Large Room (Queen Anne) is designed in the style of Sir Christopher Wren, the details being taken from Hampton Court Palace and Belton House, where Sir Christopher Gibbons executed some of his best wood-carving under Sir Christopher's direction. Its furniture is from old examples, some of which were in the possession of the Messrs. Trollope. The original chair came from the collection of Lord Hylton, Merstham House, the settee was prepared for Queen Anne's reception at Forde Abbey, while the cabinet is an old one, reproduced from a family in which it has been for generations.

When the exhibition opens the pavilion will be further decorated with paintings, as at the last Paris Exhibition, when the work was carried out with great success under Mr. Isidore Mann, now, as then, secretary of the Fine Art Committee, and the chairmanship of Sir Edward Poynter. Most of the members of the Commission have already proceeded to St. Louis, and, so far, at least, as the British exhibit is concerned, nothing will be in good time for the opening day, April 30. It now seems probable, however, that, as usual, there will be considerable delay in the installation of some of the exhibits, especially those from America itself. The excuses given for this are well known—viz., the weather, dilatoriness in starting, and unexpected blocks in the transportation facilities, and the seaboard provided by the railways.

SOAP BUBBLES.

EXPERIMENTAL DEMONSTRATIONS.

DUPLEX nature of soap bubble films. Separation of the two films either by peeling or splitting. White and black films of bubbles. The black or invisible film is transparent, and most elastic, and supports the other films. The invisible film envelopes the white and coloured films, which are movable, by internal air currents. The white or fragile film can be obtained first, and is not then followed by a coloured film.

An investigation into the physical and optical properties of soap bubble films has not been considered beneath the dignity of some of our cleverest philosophers and scientific men. Whether the following notes will throw fresh light on their constitution, I am not in a position to say. It is not likely that every one would come across an account of everything that might have been said and done even during a long lifetime. Whether their duplex nature has ever been suspected or investigated, I am perfectly unaware, but such is the following. I have been led to understand that their colours are due to a varying thickness of the solution which enter into their constitution. As ordinarily produced, their colours are of a mixed character, floating about on the surface from the action of the air upon them. It was during some experiments, I could produce homogeneously coloured films of bubbles both deep and brilliant, and after going through the prismatic gradations of colour during distention terminated in an extraordinary manner, viz., by passing through various colour stages to a white one. Then, when all the necessary conditions have been complied, this white film either became riddled with apparent holes sailing from the bottom of the bubble, or it (the white film) detached itself from the mouth of the tube from which it was blown, and gradually settled down towards the bottom until we had the extraordinary spectacle of the lower half of the bubble apparently hanging cup-shape in mid-air, detached from the mouth of the tube. This apparent mid-air space has a most singular optical property of almost perfect total absence of the power of reflecting light from the convex or concave surfaces of so-called black film, for it is necessary, in order to dispel the illusion that it has no existence, is to illuminate it with a very bright light, in order to get it to show a reflecting capacity. For convenience, I have called this film a black one, because of this difficulty of not reflecting light like the ordinary objects around.

Occasionally the whole of the white film contracts from the black one, and then nothing remains to show its existence, but a small quantity of the solution suspended as it were in mid-air for a short period. Several times during my experiments I have taken advantage of the complete stripping to draw the air out of the bubble to see if by so doing I could make it increase its reflecting power, but it failed to show any signs, although its thickness must have been considerably increased by the time its size was reduced down to that of a small pea; neither did it show any signs of colour either, or course.

How this variable thickness will affect the theory of supposing the black spot (in this case film) may be the measure of the size of the ultimate particles of matter I am not aware. A further question might be asked: Are there not more sizes than one of the ultimate atoms of matter?

It is evident from the above facts that an ordinary bubble is composed of two films, which accounts for the peculiar behaviour and movement of the colours upon it, which could not be possible without a permanent and rigid foundation for them to float upon.

Now, these two films have totally different properties in some respects, but in other respects are similar. Both are stretchable under pressure, but one more than the other before rupture. The one from which the colours are developed has the least, and consequently ruptures and slides over the more permanent, or so-called black, film, and therefore when all is in perfect order slides down under the influence of gravitation to the lower part of the film or bubble. Now, this can never take place with too much free liquid taken up by the pipe from which the bubble is blown, consequently all the liquid taken up by the pipe should be used up in the production of the bubble. But no amount of varied manipulation will suffice for, or take the place of, a proper condition of the soap solution itself, and state as to dryness of the tube used.

Limpid solutions are of no use for this purpose, and if too thick

from cold and strength, a bubble cannot be blown with it. There is a slight range of strength and temperature between these two extremes.

The most suitable orifice for conveniently limiting the amount of solution taken up is a glass tube drawn out to the size of a worsted darning needle, and the mouth of it spread out trumpet-like. The external air should be excluded from the bubble under a square glass shade, for obvious reasons. Very occasionally the coloured film has been observed to split up into holes all over simultaneously.

But the solution may be so constructed to give the white film at once, and then splitting takes place at once, immediately the bubble is blown. This would seem to indicate that there is present a larger quantity of elastic material than there is of the free liquid from which the colours are produced. Or, to put it the other way, the free liquid is not present in sufficient quantity to spread itself over the more permanently elastic or black film, only up to a certain size before its cohesive limits are exhausted.

For the constitution of the soap solution many recipes have been given, each experimenter having his own favourite formula for any special purpose or experiment he may happen to have in hand; they are all more or less complicated. For stripping experiments, nothing could be more simple, as nothing but Castile soap and pure water is necessary, of a certain consistency. For a stock mixture, take soap and cut it into small fragments, and in a bottle simply cover it with pure water, or clear rain water, stir or shake thoroughly till completely mixed, which will take some considerable time. When completely soaked, a small portion may be taken and put into a separate bottle, and water added in small quantities, thoroughly mixed and tried after each addition of water until the end in view is accomplished. It is as well to have several specimens of variable strengths, as the homogeneous colours require a much less strength for their production. This stock solution—or rather, paste—does not separate into two parts as does a weaker mixture, which is useful occasionally to dip the pipe in certain cases, when other solutions from various causes are not giving satisfactory results. The trumpet-shaped capillary glass tube should have a convenient length of indiarubber tube attached to it to blow the bubble up, and a small piece of tubing inserted in the other or mouth end. The management of this tube is of great consequence, as after a time vapour from the breath gets condensed, and the water therefrom gets blown down the tube on which the bubble is formed, and vitiates all one's endeavour to obtain uniform results. This points to the necessity for several specimens of variable strengths, so that if one fails to give good results, the stronger or weaker specimen may be at hand for use until the tube has been freed from water.

Since writing the above I have obtained a better method of getting the best consistency of the soap solution for film splitting, i.e., by reversing the mode of procedure. Take a quantity of water for the amount of solution required, and add of the soap paste bit by bit until the consistency is reached best suited for a given purpose. Shake well till dissolved, and test after the last addition is completely dissolved. Having made several specimens of variable strengths, choose that one which, after standing undisturbed about a day, has a stiff, jelly-like consistency at about 58 to 65 degrees temperature. With the mixture I have best succeeded, a bubble could not be blown at the lower temperature, and if higher than 65 degrees the splitting and peeling was very difficult to get with any amount of coaxing.

No very definite method can be given to obtain success under all conditions at every attempt. To secure unfailing good results practice, perseverance, and intelligence are three prime mental elements or roads to success, coupled, of course, with the essential material elements.

G. MARLOW.

THE SPECTACLE MAKERS' COMPANY.—The Worshipful Company of Spectacle Makers have decided, after prolonged investigation, to institute an examination and diploma in eyesight testing, specially applicable to members of the optical industry. So well has the diploma scheme of the Spectacle Makers' Company been received, that the National Association of Goldsmiths has approached the Spectacle Makers' Company with the request to undertake the examination of jeweller-opticians in order that they may gain the diploma.

IN THE WEST.

About a year ago or so Bideford Photographic Society was founded, and it has been pursuing a useful, if not a very demonstrative, course, inciting its members to good works, and gradually drawing together the fraternity of the camera. It is not every society that contains within itself workers who feel themselves capable of leading their fellows, though it is generally admitted that co-operation in this direction has a very useful effect. However, the Bideford Society adopted a somewhat novel expedient and obtained a course of lectures upon photographic subjects, by securing the services of Mr. W. E. Searley, of the County Council, during the winter session just closed. That gentleman dealt with the following subjects:—1, camera lenses and fittings; 2, exposure and exposure meters; 3, developers and developing; 4, intensification, reduction, printing, and toning, P.O.P. and bromide papers; 5, carbon, gum bichromate, platinotype, and gaslight papers; 6, enlarging, reducing, and copying; 7, lantern slide making; 8, art in photography. These proved most instructive and useful. Mr. Searley closed the series with a lecture on a trip to Lapland, Spitzbergen, and Iceland, illustrated by his own slides. The audience was a very large one, and the lecture was very heartily and deservedly applauded. The Society in recognition of his work has made him a presentation of a handsome writing case, silver mounted.

Recently a very interesting lecture was delivered at the Athenæum, Plymouth, in the rooms of the Plymouth Institution, by Mr. Charles R. Rowe, M.J.L., upon "Rambles in photographic byeways." The lecturer dealt with specialised photographic work as distinguished from the common place—the highway in photography. He showed that those who left the highway, and went into the byeways had produced very striking and frequently very valuable work. He dealt with "Nocturnal photography," with examples by Paul Martin and W. A. Fraser; flowers, W. A. Fraser. The development of the window in church architecture, Harold Baker; lightning, W. Archibald; the life history of a tadpole (radiography), W. Morley Martin; sea birds, C. J. King; small mammals, reptiles, and insects, Douglas English; crystallography, microphotography, etc., Fred Hes; and frost crystals, J. Leadbeater. The series included a splendid lot of slides and evoked very hearty applause for their novelty, great beauty, and technical quality.

Torbay Camera Society beside holding a monthly meeting has adopted the plan of circulating an album of prints every month for stirring up the emulation, and quickening the ability of its members, with very marked and excellent results, as each album appears to be an advance on its predecessor. Each member is not compelled to contribute, and, as a matter of fact, only about half do so. But the album goes to every member, and each member may contribute a criticism and award a vote. The last album has just been circulated with the following result: First, Miss Marillier, for a very effective and striking interior—a drawing-room. Second, Mr. E. Midgley, "Reredos, Exeter Cathedral," a skilful and clever example of interior architectural work. Mr. R. F. Welby is a veteran in photographic work, and his range is wide. He contributed besides an example of snapshot photography a copy of a water colour sketch by Welby Pugin, a fine bit of work. Miss Rodway's landscape work is always characterised by excellence of selection and good technique. She has recently taken up enlarging and contributed a couple of examples from the charming spot "Pittisham on the Dart." Mr. Carslake Winter Wood has two technically good subjects, the better, perhaps, being that of fishermen on the quay at Brixham. "Toilers of the Deep." Miss G. M. Rodway has sent a couple of subjects from Santa Margherita, Italy, "Lemons and mimosa," very excellent, and "Entrance to olive groves," a small picture of great merit, too small to do itself justice. "Scarborough Harbour" by Mrs. Marillier, is a very clever rendering of a shimmering sea and well-broken reflections, a highly creditable example of work. Miss C. E. Robinson is an expert in architecture, but in this case her scores best with a landscape "Bickford, on the Mendips," the charm of which would have been greater but for its biting sharpness. Colonel Macmullen's flower study is a very fine thing. Miss F. E. Welch has "The Lenywater, near Callander," a happy selection. The average of the album is excellent, and the progress of the members of an encouraging character. The membership is steadily growing. South Devon Teachers' Camera Club is somewhat, if not altogether unique in its character, as it has a membership from an area of

large size, and of scattered character. This does not, however, militate against excellent attendances. The meetings are held at various places, once a month. The last took place at the Wolborough National School, Newton Abbot, Mr. W. E. Searley is president, and he occupied the chair. After the ordinary business had been dealt with the President delivered a very practical and well reasoned address on "Pictorial Composition." The lecturer's purpose was to encourage the thoughtful use of the camera, and as far as possible, utilising the principles of composition as defined and used by painters. He very happily hit off photographers into three classes:—The scientist, the topographer, and the artist. He everly defined all three more elaborately, and though he spoke of pictorial photography it was by no means with a very big A. He did much to say upon what art was, and was not, yet he admitted it was hard to define so clearly as could be desired. It was, he thought, clearly a matter of temperament, and that without individuality there could be no interpretation of art. Art was not merely a transcript of nature. It was more than that—just that something that raised it from the commonplace. After speaking of the limitations and pointing out that the camera draws too much of the whole subject was dealt with in a broad spirit. The lecturer pointed out that, so far as might be possible, the photographer could be governed by the following principles in the arranging and selecting of his picture:—Balance, contrast, repetition, variety, gradation, repose, breadth, and simplicity. If these were kept in mind camera workers would probably take more time, do less, but get better results. The lecturer evoked hearty applause at the conclusion of his lecture. He had demonstrated his arguments with drawings on the blackboard, and by passing around reproductions from the works of the old and modern masters, all of which supported and accentuated his contentions. An excellent discussion followed, and a hearty vote of thanks was tendered to the lecturer, a well-deserved compliment.

ON THE ALTERATION OF ANHYDROUS SODA SULPHITE WHEN EXPOSED TO THE AIR.

Sulphite of soda is, as we know, usually employed in order to prevent the oxidation of developing solutions when exposed to the air, by reason of its easy transformation into sulphate. It rapidly absorbs the oxygen of the air, which acts on the developer. This oxidation, we know, may take place spontaneously prior to the sulphite being used in the preparation of developers, either during manufacture, in the vessels to which it is transferred, or in solution, when the latter is prepared in advance. Owing to this oxidability, sulphite of soda is, therefore, liable to alteration, which renders its action uncertain, and prevents uniform results being obtained in the preparation of developers. Quite recently Namias* has shown by analysis of various samples of anhydrous and commercial crystallised sulphites that these products have a variable yield of pure sulphite, declining in certain cases to 44.2 per cent., but not exceeding 90 per cent. He recognises, furthermore, that the alteration in air is more rapid in the case of anhydrous soda sulphite than in that of the crystallised form, and confirmed the experiences of Ellis and other authors† on the rapid oxidation of aqueous solutions of commercial soda sulphite in a half-full bottle. Such alteration occurs even when the operations are protected from the air.

On account of its liability to alteration, Namias recommends the replacement of soda sulphite by potassium metabisulphite,

which is a substance liable to but slight alteration.

Unfortunately, this body has an acid reaction, and considerably hinders development; whilst in order to use it under the same conditions as sulphite of soda, the addition of suitable quantities of caustic soda or of caustic soda is necessary (3.5 grm. of soda or 5 grm. of potash to 10 grm. of metabisulphite, according to Namias). We considered it desirable, before condemning the use of soda sulphite, so general in photography, and substituting an acid body

which must be neutralised at time of use, to examine the conditions under which alteration of the sulphite takes place. It will then be possible to indicate the means to be used for preventing or minimising such alteration.

We propose to determine the causes favouring oxidation, in the air, not only of anhydrous soda sulphite and of crystallised soda sulphite, but also of metabisulphite of potash and bisulphite of soda, i.e., all the derivatives of sulphurous acid most generally in use in photography.

In the following study we shall confine ourselves to exhibiting the first results of our researches; these concern only the alteration in air of anhydrous soda sulphite.

I.—ALTERATION OF ANHYDROUS SODA SULPHITE IN SOLID FORM.

We endeavoured, in the first place, to discover whether anhydrous soda sulphite oxidises in air when exposed in a thin layer, at ordinary temperature, either in relatively dry air or in air of great humidity, as well as at temperatures of 50 degrees and 100 degrees. In order to follow the alteration of the sulphite we made a quantitative analysis of its sulphurous acid by means of a liquor of iodine one-half decime normal added to 10 c.c. of liquor of sulphite brought by dilution in every case to a strength of 1 per cent. To these 10 c.c. of liquor, placed in a glass and increased by the addition of an equal quantity of water, were added a few drops of starch. To this mixture was added little by little the titrated liquor of iodine until of a fixed blue colour.

The following are the results of the titration effected on an anhydrous sulphite:—

Date of Titration.	Relatively dry air Temp. 15°.	Very humid air Temp 15°.	Sulphite kept at 50°.	Sulphite kept at 100°.
5 December.....	29 ccm. liq. iode	29 ccm. liq. iode	29 ccm. liq. iode	29 ccm. liq. iode
8 " " " " " "	29.1 " " "	28.7 " " "	29 " " "	29 " " "
12 " " " " " "	29 " " "	26 " " "	29 " " "	28.1 " " "
16 " " " " " "	28.8 " " "	25.5 " " "	28.0 " " "	29 " " "
21 " " " " " "	29 " " "	24.1 " " "	28.7 " " "	29.1 " " "
30 " " " " " "	28.5 " " "	24 " " "	28.5 " " "	29 " " "
5 January	28.5 " " "	21 " " "	28.7 " " "	29 " " "

The preceding results show, therefore, that anhydrous sulphite of soda in solid state, and dry, does not appreciably alter when exposed to the air, even at a temperature of 100 degrees. Alteration occurs, but only slowly, when this product is exposed to very humid air. In all cases, however, the conditions most favourable to oxidation were present, the sulphite having been exposed to the air in the form of a very thin layer.

II.—ALTERATION OF SOLUTIONS OF ANHYDROUS SODA SULPHITE.

Various authors have indicated the alteration undergone by solutions of soda sulphite, but no precise observation has up to the present been made on the rapidity of such alteration at a fixed concentration, nor on the influence of temperature and concentration on the speed of oxidation.

(a)—INFLUENCE OF CONCENTRATION AT ONE TEMPERATURE.

With the same sample of anhydrous soda sulphite we made two litres of solutions at 1 per cent., 3 per cent., 5 per cent., 10 per cent., and 20 per cent. Each of these solutions was divided into two equal parts, and each part, about a litre, was placed in two two-litre bottles, one of which was corked and the other left uncorked, in order to examine the influence of corking in a half-filled bottle. Each solution was titrated daily.

For this titration all the liquors were suitably diluted in such manner as to contain only 1 per cent. of sulphite, 10 c.c. of liquor was used, the operations being carried out exactly as indicated above.

The results found in these titrations are not positive—their comparison only is interesting. The numbers obtained vary, in fact, according to the size of the bottles, the quantity of liquid they contain, the surface of liquid in contact with the air, and the exterior temperature.

Further, in the same solution one number is not altogether comparable with those following, the less so as the quantity of liquid

* Bulletin de la Société Suisse de Photographie, p. 513 (1903).

† Hauberriiser : Das Atelier de Photographen, p. 129 (1903).

* This anhydrous sulphite, 10c.c. of 10 per cent. solution of which require 29c.c. of liquor half decime normal (6 gr. 35 per litre) contains, according to calculation, 91 gr. 35 per cent. of pure Sulphite $\text{SO}_3 \text{Na}_2$.

contained in the bottle becomes weaker in proportion to the daily titration.

The surface of absorption of the oxygen remains, in fact, the same, whatever the quantity of liquid.

Also, it may be noticed that in those solutions which oxidise less rapidly (those in which a large number of titrations has been made) the rapidity of oxidation increases in proportion to the increase in the number of titrations.

The following table indicates the results of our operations:—

Strength of Solution.	Duration of Contact with the Air.	Quantity of Oxidized Sulphite, per 100 gr. Total used.	Quantity of Oxidized Sulphite, per 100 c.c. After 7 days.
1 p.c. solution.			
Half-filled bottle, open	After 7 days, total oxid'n.....	100 p.c.	1 gr.
Half-filled bottle, closed.....	After 7 days, total oxid'n.....	78 p.c.	0 gr. 73
3 p.c. solution.			
Half-filled bottle, open	After 7 days, total oxid'n.....	100 p.c.	—
Half-filled bottle, closed.....	After 14 days, total oxid'n.....	100 p.c.	—
5 p.c. solution.			
Half-filled bottle, open	After 7 days, total oxid'n.....	61 p.c.	1 gr. 83
Half-filled bottle, closed.....	After 12 days, total oxid'n.....	100 p.c.	—
10 p.c. solution.			
Half-filled bottle, open	After 7 days, total oxid'n.....	90 p.c.	0 gr. 6
Half-filled bottle, closed.....	After 1 month.....	72 p.c.	—
20 p.c. solution.			
Half-filled bottle, open	After 7 days, total oxid'n.....	27 p.c.	1 gr. 35
Half-filled bottle, closed.....	After 14 days, total oxid'n.....	100 p.c.	—
30 p.c. solution.			
Half-filled bottle, open	After 7 days, total oxid'n.....	10 p.c.	0 gr. 5
Half-filled bottle, closed.....	After 1 month.....	81 p.c.	—
40 p.c. solution.			
Half-filled bottle, open	After 7 days, total oxid'n.....	19 p.c.	1 gr.
Half-filled bottle, closed.....	After 1 month.....	98 p.c.	—
50 p.c. solution.			
Half-filled bottle, open	After 7 days, total oxid'n.....	5 p.c.	0 gr. 5
Half-filled bottle, closed.....	After 1 month.....	32 p.c.	—
60 p.c. solution.			
Half-filled bottle, open	After 7 days, total oxid'n.....	2.4 p.c.	0 gr. 43
Half-filled bottle, closed.....	After 1 month.....	14 p.c.	—
70 p.c. solution.			
Half-filled bottle, open	After 7 days, total oxid'n.....	0.5 p.c.	0 gr. 1
Half-filled bottle, closed.....	After 1 month.....	6.5 p.c.	—

The above table shows that the relation between the amount of oxidised sulphite at the end of the same period, in solutions of variable concentration, and the total quantity of sulphite contained in the same volume of solution, is weaker the greater the concentration.

Thus, it is seen that after seven days the total of the sulphite, 100 per cent. is oxidised in the 1 per cent. solution, whilst at the end of the same period there is only 2.4 per cent. of the total quantity of sulphite that has disappeared in a 20 per cent. solution.*

If the quantity of oxidised sulphite in 100 c.c. of solution be calculated it is seen that this quantity is weakest in the 20 per cent. solution. Thus, in place of about 1 gr. of oxidised sulphite after seven days to 100 c.c. of liquid in the 1 per cent. solution, only 0.48 is found in the 20 per cent. solution. The alteration of 20 per cent. solution of anhydrous sulphite may, therefore, be considered as notably less than that of a weaker concentration.

B.—INFLUENCE OF TEMPERATURE ON THE SAME CONCENTRATION.

We repeated experiments similar to the foregoing, using 1 per cent. solutions of anhydrous sulphite of soda, and maintaining these at temperatures of 15, 25, 35, and 45 degrees, respectively. Each test was made on a litre of liquid placed in two-litre bottles, the same temperature being maintained for an open and a closed bottle.

In the open bottles the following total oxidation resulted:—

- After 6 days, at 15 degrees.
- After 4 days, at 25 degrees.
- After 3 days, at 35 degrees.
- Après 2 days $\frac{1}{2}$, at 45 degrees.

In the closed bottles the alteration was complete

- After 14 days, at 15 degrees.
- After 12 days, at 25 degrees.
- After 12 days, at 35 degrees.
- After 11 days, at 45 degrees.

Therefore, the higher the temperature the more rapid is oxidation, particularly if an open bottle be used.

* As we have pointed out above, the 2 litre bottles which contained 1 litre of liquid, were half-full at the commencement of the trials, but when the experiments were repeated during a month there remained finally about 50 c.c. of liquid in the 2-litre bottle.

C.—ALTERATION OF SOLUTIONS AT THEIR BOILING POINT.

We have endeavoured to discover with what rapidity oxidation takes place in the case of solutions of anhydrous soda sulphite, in different degrees of concentration, when placed in contact with the air in their boiling state. One per cent., 3 per cent., 5 per cent., 10 per cent., and 20 per cent. solutions were used, each solution being titrated before heating, then raised to and maintained at boiling point in two-litre capsules, care being taken to make up for the loss of water in proportion to evaporation. After a suitable time, each operation was stopped, and titration carried out. In all these titrations the solution was restored, after cooling, exactly to its original volume, then diluted to correspond in strength to 1 per cent. in relation to the original liquor.

The following table indicates the results obtained in the titration of solutions of anhydrous sulphite in various degrees of concentration after boiling for variable periods:—

Strength of Solution.	Duration of Boiling.	Quantity of Oxidized Sulphite, per 100 gr. Total used.	Quantity of Oxidized Sulphite, per 100 c.c. of Solution, after 2 hours' boiling.
1 p.c. solution	2 hours. 2½ hours.	97 p.c. 100 p.c.	0 gr. 97 —
3 p.c. solution	2 hours. 4 hours.	19 p.c. 44 p.c.	0 gr. 57 —
5 p.c. solution	2 hours. 5 hours.	13.6 p.c. 27.5 p.c.	0 gr. 68 —
10 p.c. solution	2 hours. 10 hours.	2.7 p.c. 14 p.c.	0 gr. 27 —
20 p.c. solution	2 hours. 12 hours.	0.8 p.c. 4.5 p.c.	0 gr. 16 —

Examination of the figures of this table shows that at their boiling temperature the ordinary solutions are considerably more susceptible to oxidation than concentrated solutions. This result may be deduced not only from comparative examination of the amount of oxidised sulphite, in relation to 100 gr. of sulphite employed, but also in relation to the same volume of solution.

If, for example, solutions at 1 per cent. to 20 per cent. be compared, it is seen that after two hours boiling, in the first 97 per cent. of the total sulphite had oxidised, and 0.8 per cent. in the second, or 0.97 of substance to 100 c.c. of 1 per cent. solution, and 0 gr. 16 to the same volume of 20 per cent. solution.

CAUSE OF OXIDATION OF SOLUTIONS OF SODA SULPHITE.

We have sought for the cause to which may be attributed oxidation of solutions of soda sulphite. The oxygen originally dissolved in the water appears to us to have no perceptible influence on this alteration, for no appreciable difference was observed in the rapidity of oxidation when using solutions prepared with boiled water and unboiled water kept in hermetically sealed bottles.

In every case, solutions of anhydrous soda sulphite undergo no appreciable alteration no matter what their concentration, except after a very long period, if kept in a full bottle hermetically closed, whatever the exterior temperature.

The oxygen of the water then appears to have no connection with the phenomenon, and the oxygen of the air alone seems to be the reaction agent. Doubtless, it is during its dissolution in the liquid in proportion to its fixation that oxidation occurs.

May it not be deduced from this that if ordinary solutions oxidise more readily than concentrated solutions, it may well be because oxygen is less soluble in the latter than in the former?

CONCLUSIONS.

From the preceding experiments a series of practical conclusions may be drawn.

(1) Anhydrous soda sulphite exposed to air, even in a thin layer, at ordinary or high temperature, undergoes no appreciable alteration, except the atmosphere be very humid.

(2) Weak solutions of anhydrous soda sulphite oxidise very rapidly in the air at ordinary temperature. In solutions of various degrees of concentration the relation between the quantity of oxidised sulphite at the end of the same time, and the total quantity of sulphite dissolved, is the weaker, the greater the concentration of the solution.

5) Concentrated solutions, from 20 per cent., are but very slightly stable, even if kept in an uncorked bottle, and present to the air a large surface of contact. In order to keep sulphite in solution it is, therefore, best to use it in concentrated form.

4) At boiling point, solutions of anhydrous soda sulphite oxidise the silver rapidly the greater their dilution. From 20 per cent. these solutions may be kept at boiling point, in the air, without appreciable variation.

Exhibitions.

HOUSE EXHIBITION AT THE ROYAL PHOTOGRAPHIC SOCIETY.

INTERVALS of such length are now allowed to elapse between the house exhibitions held by the Royal Photographic Society at its domicile, 66, Russell Square, that the series has almost forfeited its right to be titled a series; moreover, the present exhibition departs from the custom of including only the work of a single person, and in this respect it is on different lines from its predecessors. We understand that it was intended to include work by several professional photographers who at the last moment were unable to send in, but, except that the number of pictures shown is rather small, there is no reason to regret that the exhibition is confined to the work of three exhibitors.

The three exhibitors are William Crooke, Frederick Hollyer, and T. C. Turner, and the work of each may be taken as typically representative of the result of a different influence. Frederick Hollyer is best known by his photographic reproductions of works of art, particularly paintings. His success in this branch of photography is everywhere recognised, and it is undoubtedly due, apart from the technical photographic perfection of his work, to his intuition of the feeling of the man whose work he is translating. Knowledge of the methods of the painter and sympathy with his desires constitute the secret of Mr. Hollyer's aptitude at rendering the spirit as well as the details of his copy in the monochrome of a photograph. Intimate acquaintance with and appreciation of the plastic facilities of the brush help to give direction to Mr. Hollyer's ideas in dealing by photography with subjects direct from life. There is not the slightest suggestion of the methods or ideals of the ordinary photographer in any of his work. He sees his model with the eyes of a painter, and he earnestly endeavours to make his production as a painter would make it, entirely without regard to any conventional ideas of what a photograph should be. In this endeavour he succeeds entirely. His portraits are the characteristic of photographic copies of paintings, so much so that many of them might be easily mistaken for such, and they often are just the defects that photographic copies of paintings are subject to.

The method of mounting frequently adopted, upon canvas so that the grain of the canvas is apparent, the semi-glossy surface, and the framing, without a glass, help to complete the illusion. These means secure effect are legitimate enough, but in less capable hands their employment might easily have no other result than to suggest that an imitation had been attempted. Hollyer's work does not suggest that. It comes as an afterthought that its similarity to painting is due to anything further than the treatment of the subject and the minor details of the production are accepted as carrying out the spirit of the work.

A characteristic of Hollyer's work is its spontaneity. To the photographer with the usual experience in posing, it gives the impression of the result of happy accident rather than of a thought-out scheme. There is no rigging in any way or faking of any kind, not even to the extent of removing or modifying details which might well have been altered. Hollyer's portraits are full of character, but it is his fortune to be able to choose persons of character for portrayal. In any respects Hollyer's work bears a strong resemblance to that of the late Mrs. Julia Margaret Cameron. There is the same breadth both in conception and execution and the same disregard for conventionalities, and though a generation of photographers has passed since her time, among them there is not one who has so nearly followed the same path.

Much as there is in common in the work of Hollyer and William

Crooke, as indeed there must be much in common in the work of all artists who use the same means of expression, there is little similarity in the results. Crooke does not go to the painter direct for his guidance but takes his cue from a branch of art more nearly allied in its requirements and limitations to photography. As Hollyer directly follows the lines of the painter, Crooke as directly follows the lines of the engraver, the etcher, and the draughtsman in black and white. It is the engraver's business to translate into monochrome pictures which in addition to contrasts in tones contain contrasts in colours, and to do so in a way that preserves the semblance and the spirit of the original in spite of the limitations imposed upon him. The etcher and the black and white artist, although they may work directly from nature, have also the same translation to effect, the photographer likewise. The art of them all is to deal with contrasts and gradations. What, then, is more natural than for the photographer to adopt the methods, as far as his craft will allow, of those aims which are so closely allied with his own? That Crooke sometimes finishes and mounts his pictures so as to imitate the appearance of old engravings, even to the lines and lettering, constitutes but a minor point of resemblance. It is not in the get-up of the pictures but in their treatment that the influence over their creation is shown. Minutely perfect in detail, one instinctively feels that not a line or a tone exists that has not been the subject of thought, yet, withal, the effects are so natural that there is no appearance of labour. Crooke is usually sparing of the higher tones, but his masses of shadow are not empty spaces but full of subtle gradations, and his flesh-tints, although he uses the strongest lighting involving deep shadows, are so well managed that the inky blackness which almost universally characterises similar attempts in photography are absent. The two pictures, "Summer" and "A Lady of High Degree," alike, inasmuch as they both contain faces shaded by hatbrims, are examples of this able treatment, while some of the feeble attempts at chiaroscuro of a similar kind which hung a year or so ago on the same walls during the exhibition of American work, represented the other extreme. As most of the pictures are, on the whole, low in tone, and the lighting of the room is not brilliant, the effect of several hung together is somewhat sombre, but this is not the feeling that the individual pictures would produce.

In the work of Thomas C. Turner there is the exemplification of yet another path to success in photography. Throughout there is nothing suggestive of any influence outside photography except what may be looked upon as traditional. The earliest photographers, provided with a chemical means of doing what had hitherto required years of study and practice to do by hand, were unprovided with artistic methods suited to the new departure. Naturally they adopted, as far as they could, the practices of their predecessors and contemporaries—miniaturists and painters. But the imaginative accessories of the latter, pillars, curtains, pedestals, balustrades, etc., together with park-like landscapes, when roughly imitated in the solid or painted upon canvas under the searching power of the lens, and used unintelligently and without discretion, made but a ridiculous travesty of what under idealistic treatment served a useful purpose. It was when the *carte de visite* boom was on the wane that photographers struck out a course for themselves, and for a long period we have had a treatment of portraiture on lines entirely peculiar to photography. But while generally photographic portraitists have been content to follow popular taste, some of them, among them T. C. Turner, have sought to lead it. No one could mistake any of Turner's works for an engraving or a copy of a painting. It is distinctly photographic in character, and the natural evolution of the *carte de visite* of Doderer. Improved processes, better materials and greater facilities have done much towards advancement, but all these, as we may see every day by looking around, are in themselves of little avail without exceptional skill and taste in the man who directs the operations. Photography has existed from the first with an unmerited slur on its character. In the beginning artists with other means of expression thought and were terribly afraid it would supersede their work. Nowadays some of them dislike photographs because they are like photographs, while others sneer at them because they are like something else. A new generation, it is to be hoped, will recognise that a photograph pure and simple may possess qualities which deserve admiration, and that a photographer who conscientiously works out his art by the means best suited to the possibilities and limitations of his method of expression is not unworthy of the brotherhood.

MR. TOM REVELEY'S EXHIBITION.

At the Camera Club a small one man show, the work of the above-named professional photographer, of Wantage, affords a display interesting especially to those concerned in the breeding of pedigree animals, whether horses, dogs, cattle, or sheep. Mr. Reveley has attained an extremely creditable excellence, artistic, technical, and one may add, occasionally humorous in photography in this special direction. While very careful in the correct posing for points, he has succeeded also in giving artistic results, frequently very difficult to obtain with such subjects, and his technical work, especially in the marvellous reproduction of the texture of the coats of the animals, is very attractive. An excellent example of large and difficult grouping is a picture which perpetuates the memory of a visit paid by the King and Queen (when Prince and Princess of Wales) to the birthplace of their great ancestor King Alfred.

Nor has Mr. Reveley neglected human kind for the lower races. In portraiture he exhibits some examples of high merit, those of Professor Wicksteed (the Dante specialist), the Dowager Countess of Crawford, and others testifying to his power in that direction, as also one of the Right Hon. Sir Henry Elliott, G.C.B., who faces us here as the country squire in quiet retirement from many years of Diplomatic toil.

Visitors can obtain cards of admission to view this collection by application to the Hon. Secretary of the Camera Club, and on Tuesday and Friday afternoons during April from 3 to 5 p.m. on presentation of visiting card.

FORTHCOMING EXHIBITIONS.

April 20-26.—Swansea Photographic Club. Hon. Secretary, W. R. Stephens, 14 and 15, Temple Street, Swansea.

May 2-4.—Bristol Eisteddfod. Photographic Section. Hon. Secretary, Arthur B. Cleaves, Westbury-on-Trym, Bristol.

May 11-18.—Plymouth Photographic Society. Hon. Secretary, Wilfred Grist, 105, Old Town Street, Plymouth.

May 16-28.—Photographic Society of Ireland. Hon. Secretary, E. Webb-Smith, care of Royal Dublin Society, Kildare Street, Dublin.

May 24-28.—Devonport Camera Club. Hon. Secretary, A. J. Catford, 78, Charlotte Street, Devonport.

Patent News.

The following applications for patents were made between March 21, and March 26, 1904:—

Apparatus.—No. 6,855. "Improvements in photographic cameras, plate holders, focus screens, and means of attachment to stands." Henry Major.

Cameras.—No. 6,839. "Improvements in photographic cameras." The Thornton-Pickard Manufacturing Company, Limited, George Arthur Pickard and Frank Slinger.

Diaphragm Adjuster.—No. 6,974. "Improvements in appliances for adjusting and working iris diaphragms of photographic cameras." Alfred Watkins and Charles Godfrey Woodhead.

Printing Apparatus.—No. 7,009. "Improvements in photographic printing apparatus." Complete specification. Hervey Heman McIntire.

Film Cartridges.—No. 7,131. "Improvements in and relating to photographic film cartridges." John Laird Nuttall and Thomas Arthur Harrison.

THE Discovery Antarctic Exhibition. — It is stated that some thousands of photographs were taken on the expedition, covering natural features and bird and animal life. The main practical interest of the expedition lies in the results of the magnetic investigations. Continuous observations were taken in the neighbourhood of the Magnetic Pole.

New Apparatus, &c.

The "Falloroll" Aluminium Telescopic Walking Stick Stand.—Sold by Jonathan Fallowfield, 146, Charing Cross Road, London, W.

This latest addition to the long list of telescopic and walking stick tripods already on the market has, at least, the merit of fully bearing out its title, and is probably better than most "walking stick" stands we have seen. When closed it resembles nothing so much as a neat ebony walking stick with crook handle, silver ferrule, and band. As a walking stick it is lighter than ebony, and is well

balanced. By unscrewing the crook and ferrule the stick opens into the familiar tripod, which can now be doubled in length or height by pulling out inner draw tubes. A neat little turntable can be screwed on the top, which is then ready to take a light camera. We question its rigidity with a heavy camera, but its intention is obviously to supply a handy and portable tripod in an unostentatious manner, when on tour with a hand camera. In this it succeeds admirably. Its cost in aluminium is not excessive.

BUTCHER, Curnow, and Co., Limited.—The above-named company has been registered with a capital of £6,000 in £1 shares. Object, to acquire the business of wholesale and retail chemists, retail dealers in photographic apparatus, etc., carried on at 33 and 35, Tranquil Vale, Blackheath, as W. Butcher and Son and F. E. Butcher of the first part, W. A. Curnow of the second part, J. L. Savage of the third part, and the company of the fourth part, and to carry on the said business and any other incidental thereto. No initial public issue. The first directors are W. F. Butcher, F. E. Butcher, W. A. Curnow, and J. D. Savage. Qualification, £500. Remuneration of W. F. Butcher as chairman, £50 per annum; of others, as fixed by the company. Registered office, 33-35, Tranquil Vale, Blackheath.

How to Make Post-cards Dry Flat.—Everyone who has printed post-cards knows the inconvenient way they have of curling when dry. After many experiments I have succeeded in drying them almost flat, and as the process employed requires no expense, skill, or trouble, I trust that it will prove of interest to printers of post-cards. The procedure is as follows:—Two pieces of wood are tacked on a piece of board four inches apart (preferably putting a sheet of blotting-paper under, so as to absorb the water that drains from the post-cards). When the post-cards are washed, take them out of the final water and place them one by one between the two pieces of wood in a curved way, film upwards. Allow them to stay so until thoroughly dry, then take them off, when they will after a little while flatten themselves. If they are wanted quickly, put them under some weight, say between two books. I have dried post-cards more or less flat in other ways, but this one has proved to be the simplest and cleanest.—John Mallia, in "The Bromide Monthly."

RECENT ASTRONOMICAL RESEARCH.

[From "Popular Astronomy."]

I.

It is our aim, each month, in a general way, to call attention briefly to some of the more prominent lines of original astronomical work, in regard to plans, methods or results, or, in other respect, which may seem to be very useful to those interested in astronomy. Photography has come into such general use in some branches of the science that we now wonder that so very efficient aid in astronomical research had not been put to place of service long ago. The great star charts of the heavens, observations of Eros, the work on nebulae and comets are some of the important lines of work in which photography works specially well.

Harvard College Observatory in Cambridge and at its station in Peru has done, in the last few years, a vast amount of astronomical work by the aid of photography chiefly. In Professor W. C. Pickering's last report is found a brief statement in this regard that is well worth copying, for the general reader. It is as follows:—

"The problem of obtaining the greatest return for astronomical research from a given expenditure of money should be the principal concern of every astronomer. It is obvious that no single observatory can accomplish as much and as good work as could be done through the efforts of the entire astronomical world. The present attempt on the part of this Observatory to secure an endowment for international astronomical research has led certain persons to infer that the present needs at Harvard are supplied. An important part of this very plan is to enable a large Observatory to do this, which can undertake to great advantage large pieces of routine investigation quite beyond the reach of the smaller observatories, to use its resources to the best advantage. It can co-operate with others, and thus bring the energy of many minds to bear upon a single problem. As an illustration, it is recognised that the distribution of the stars in space is one of the most important problems in astronomy. This investigation depends on the accurate measures of the light of stars in all parts of the sky. But little work of this kind has been done on the light of the southern stars. Special attention has been paid to photometry at this Observatory, and we have an excellent southern station where such work could be carried on to great advantage. An expenditure of one thousand dollars annually for five years would go far to provide for this want; but as the expenses here for the last year have exceeded the income, additional work cannot be undertaken. Again, the Harvard collection of astronomical photographs gives the history of the stellar universe for the last fourteen years with a completeness not attempted elsewhere; but these photographs are of little use unless a careful study is made of them. A satisfactory plan has been prepared for organising a corps of observers at a cost of about five thousand dollars a year, for studying these photographs. The Carnegie Institution appropriated 2,500 dollars last year for this work, but gave no assurance that it would be increased, or even continued. Results have already been obtained which show what might be expected from a permanent maintenance of this work, but the appropriation is not continued much work will be lost, and many assistants who have been carefully trained will be obliged to seek work elsewhere. The great increase in the resources of the Observatory has not been accompanied by a similar increase in the amount of capital available for plant. Accordingly, the buildings and instruments here, purchased mainly from income, are very inferior to those of other observatories whose endowment is much greater. The anonymous gift of 1902 has been of the greatest service in this respect, since it will provide two reflectors of twenty-five inches aperture, one for use on the northern, and the other on the

southern stars, and has given us a fireproof wing to the building already used for storing and studying the photographs. The cost of the entire building and wing was only about 20,000 dollars, and two similar buildings would provide for a much needed new library for the Observatory, computing rooms, photographic laboratory, and a workshop. All of this work is now carried on in very inferior wooden buildings, some of them more than half a century old. Much money is also spent in strengthening floors and repairing foundations; and the danger from fire is ever present.

If the sum of 50,000 dollars could be expended during the next ten years for such researches and buildings as those mentioned above, it is believed that a relatively large return in scientific results would be obtained. Our expenses now slightly exceed our income, and if they are cut down, a proportionately greater diminution in work will ensue. An unrestricted fund like that mentioned above would permit our present appliances to be used to the best advantage. Whatever may be the future of the Observatory, there is no doubt that a reasonable sum could be wisely expended at once, while a delay of several years may bring other conditions less favourable to effective expenditure, and will certainly cause some needs to be neglected which now seem most urgent."

Another piece of excellent photographic work is found in the new book prepared by Professor William H. Pickering of Harvard College Observatory, titled, *The Moon*. This volume is a summary of the existing knowledge of our satellite with a complete photographic atlas; it is published by Doubleday, Page, and Company, of New York, the net price being ten dollars. The description of this book consists of thirteen chapters, embracing 103 pages, large size, with wide margin; very fully illustrated with drawings and half-tone cuts, interspersed in the reading matter.

In the text the author considers the origin of the Moon; its rotation, distance, orbit, light, libration, gravitation; atmosphere, water, temperature; origin of the lunar craters; illustrative artificial craters; origin of the various formations; active lunar craters, riverbeds; ice on the Moon, the bright streaks; vegetation, the lunar canals; recent investigations; fancies, apparent size, suppositions, influence on the weather; history of lunar research; the photographic atlas, the map of the Moon, and lunar altitudes.

In his treatment of these themes, the author has passed by almost all the common-place information found in the ordinary text-books of astronomy, and has presented the latest phases of study known to the modern selenographer in plain and untechnical language. This fact alone makes the book a very useful one for the popular reader, the student and professional scientist as well.

It may be known to some of our readers that the author of this new volume recently had charge of a party from Harvard College Observatory which went to Jamaica, and there made a very complete and valuable set of Moon photographs. These have been related and arranged to form the atlas before referred to. In planning how to take the photographs, it was decided to divide the diameter of the Moon, east and west, into eight equal parts and erect perpendiculars at the dividing points which gave in all sixteen regions. Of each of these divisions five photographs were taken, making eighty in all, which covered the entire, visible surface of the Moon five times. The views for each region are, one at lunar sunrise, one two days after sunrise, one at lunar noon; another two days before lunar sunset, and the last at lunar sunset. The manifest advantage of this plan is, that it shows the same objects on the Moon's surface, at least, under five different phases of illumination, to say nothing about some of the overlapping parts of the plates which appear as many as ten times in the series. This fact suggests a pretty severe test on the skill of the artist to get all parts of these Moon pictures so well in the focus of his instrument that one does not notice obtrusive lack of definition in any. It appears to the writer that not all the pictures are equally sharp or equally good; but the wonder is that there are not greater differences in merit among so many taken within a period of seven months.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
8 and 9.....	West London Photo. Society.....	Annual Exhibition.
8.....	Plymouth Photo. Society	Platotype Printing. Mr. Alfred W. Hicks.
9.....	Borough Poly. Photo. Society	Bohemian Concert.
9.....	Aberdeen Photographic Assoc.....	Slide Competition.
11.....	Oxford Camera Club	Portraiture. Miss Hopkins.
11.....	Ulster Amateur Photo. Soc.	Photographic News Prize Slides.
11.....	Glasgow & W. of Scotland P.A.	Enlarged Negatives. Demonstrated. Mr. J. W. Downs.
11.....	Southampton Camera Club	The Bernese Oberland. Illustrated. Mr. W. R. Kay.
12.....	Royal Photographic Society	Demonstration of the Author's Method of Determining the Focal Length and the Aberrations of a Photographic Objective. Reg. S. Clay D.Sc.
12.....	Rotherham Photo. Society	Ortho-chromatic v. Ordinary Plates. Demonstration. Mr. J. W. Charlesworth.
12.....	Glasgow Southern Photo. Assoc.	Control in Development. Mr. Wm. Goodwin.
12.....	Birmingham Photo. Society	Some Photo-Optical Instruments. Mr. Wardell.
12.....	Croydon Nat. His. and Sc. Soc.	Geological Section.
13.....	Nottingham Camera Club	Practical Night. Subject to be arranged.
13.....	Cricklewood Photo. Society.....	Apparatus Night and Sale and Exchange.
13.....	Everton Camera Club	Half-day Outing.
13.....	Bath Y.M.C.A. Camera Club.....	Exhibition of Prize Lantern Slides.
14.....	Liverpool Amateur Photo. Assn.	Photography on Appreciation. Mr. W. A. Taylor.
14.....	Richmond Camera Club.....	Java: Its People and Temples. Mr. Sargent.
14.....	Everton Camera Club	Half-day Outing.
14.....	London and Prov. Photo. Assoc.	Natural History Photography. Mr. G. T. Harris, F.R.P.S.

CAMERA CLUB.

THE lecture season at the Camera Club is fast drawing to a close, and there have been signs lately in reduced attendances that the counter-attractions which the improved weather has rendered possible have had their effect. But several good things have been kept until the last. "Comedy in Art" was the title of a lecture by Mr. T. C. Hepworth on the 17th ult., the subject covering a wide field, as its title indicated. It began with prehistoric cave drawings and ended with Phil May.

Prehistoric man also came under review the following week, when Mr. Cornelius Robbins told of an interesting find of remains which he had had the opportunity of seeing and photographing. On Thursday, the 24th, Mr. Frederick Enoch gave "Illustrations of Insect Life"—a lecture which was especially interesting from the circumstance that nearly the whole of the lantern slides were produced by the Sanger-Shepherd colour process. We believe that this is the first time that a lecture on a natural history subject has been thus illustrated. Pictures of flowers and fruit we have seen taken by the process without number, and such still-life studies are comparatively easy of accomplishment. But Mr. Enoch has succeeded in photographing living insects, which are as likely as not to fly or crawl away in the middle of an exposure. And when we remember that in this colour work the exposure is rather protracted the merit of having secured such pictures is much enhanced. On the 28th ult. there was no lecture, the evening being set apart for the consideration of any question that might be raised or any novelty that might be brought forward. The members were fortunate in having brought under their notice three things which were new, two of which were submitted to scrutiny for the first time.

Mr. Franklyn exhibited his tripod stand, which is certainly a very ingenious thing. When folded up it is of the same size and has much the same appearance as an ordinary folding tripod, only that it clips together without straps, and has a convenient handle at one end by which it can be carried. It has no loose triangular head, but in place of this each of its component legs has a hinged piece of cloth-covered wood with a hole in it. These when brought together, with

the usual T-screw inserted in the holes—now brought one above the other—constitute the head, a flexible head, which by a turn of the screw or adjustment of the hinge screws can be turned in any direction with the greatest ease. With this stand the worker can turn his camera vertically upwards or downwards or in any direction which he pleases. And he can get the instrument truly level, however uneven be the ground upon which the tripod points rest. The stand is 5ft. 3in. in height, but it shuts up to the space of an ordinary 4ft. 10in. stand. The stand is intended primarily for landscape and architectural work, but its power of allowing the lens to point downwards should make it useful for copying many things which by their nature must lie flat.

Mr. Hector Maclean then introduced to the meeting the next novelty, which was a method of printing in three colours invented by Herr Szczepanik. By the courtesy of Mr. Gamble (Messrs. Penrose and Co.), he was able to show a number of specimens printed by this method. A special paper is employed which has received three coatings, of either collodion or gelatine—it was not quite clear which medium was used—each stained with a fugitive dye—blue, yellow, and red respectively. The paper was finally treated with oil of aniseed, which acted as a sensitiser. If such paper be exposed to light beneath a red glass all the colours except red are bleached out of it, if beneath a yellow glass nothing but the yellow dye remains, and if beneath blue glass everything disappears from the paper but the blue dye. So that if a coloured transparency, such as a church window, were exposed to light with the paper beneath it a correct copy of the original would be obtained. The specimens shown had been procured in this manner from designs in imitation stained glass, known as "glacier" decoration, and their colours were extremely brilliant. The exposure necessary for such work ranges between 30 and 60 minutes in bright sunshine, according to the nature of the positive employed, but the inventor has under favourable conditions obtained a print in ten minutes. No development or toning is required, but in order to make the picture permanent it must be treated with benzine in order to remove the aniseed. The film is then hardened in alum solution or formalin, and the dyes are fixed in a mordant—i.e., acetate of alumina.

The inventor and others are now busy in prosecuting experiments with a view to greatly shorten the exposure, and they have hopes that before long it will be possible to obtain a picture by exposing the film to the direct action of the lens in the camera. This would result in a photograph in natural colours of the kind that the man in the street has long looked forward to. Perhaps Mr. Maclean was rather too sanguine in foreshadowing the time when this process would supersede the tintype at places of popular resort, and when for sixpence holiday-makers could get coloured photographs as easily as they get plain ones now.

The process is certainly a very promising one, and it should indicate an easy method of obtaining duplicates of lantern slides in colour prepared by the Lumière or the Sanger-Shepherd method, for we suppose that glass can be coated with the dyed films as easily as paper. Photographic prints coloured by hand could also be used in the same manner. We understand that this paper will soon be on the market, so that our readers will have an opportunity of trying it for themselves.

One more novelty was brought before the Camera Club, and this time by one of its oldest members. Mr. Davis had a lens to show, a single lens, but one of somewhat peculiar construction. We all know how useful it is on occasions to have command of a single lens of long focus. But such a lens, if used to cover a large plate, has its drawbacks; for one thing it is almost too large to be conveniently portable. Mr. Davis gave the diameter of a single lens of the ordinary type with 22 inches focus as being $3\frac{1}{2}$ inches. He had long had the idea that this unwieldy thing could be reduced to more reasonable limits by cutting a big piece off its margin, but he could not get any optician to entertain the idea. At last he discovered one who was not too conservative to consider the matter, and who made for him the lens which he showed, which had the desired 22in. focal length, with a diameter of only 1 $\frac{1}{2}$ in. In other words, it works with an aperture of f/16. The image given is rectilinear, as was shown by a negative of an architectural subject handed round for examination, and the price paid for the lens—again we take Mr. Davis's estimate—was about one-tenth of that which would be asked for a lens of the same type not shorn of its marginal rays.

News and Notes.

MESSRS. MORLEY AND COOPER, 271, Upper Street, London, N., send their latest photographic catalogue. It is very complete, and includes nearly everything necessary for the amateur or professional. **SOUTH London Photographic Society**.—The balance sheet of this society is to hand, and shows a most successful year passed, and that the Society is in a sound financial state, with a satisfactory balance hand. We feel sure the announcement of the resignation of Mr. Calder Marshall, the energetic hon. secretary, will be the occasion of much regret.

MESSRS. NEWMAN AND GUARDIA, of 90-92, Shaftesbury Avenue, have sent us their 1904 hand camera list. It is a handsome brochure, and contains full particulars of the well-known N. and G. cameras and the Nydia; a supplement also deals very fully with the Cyclops focussing focal plane camera.

SOUTHAMPTON Camera Club.—A lecturette competition was held at the Club Rooms on March 28th. Messrs. Henley, Legg, Gibbings, Kay, and Winzar competed. Mr. Gibbings's discourse on the photography of waterfalls, illustrated by lantern slides, was awarded the Club certificate. Mr. W. R. Kay's description of a visit to Dinan and district took second place.

We have received an attractive little price list from Messrs. Henley and Co., of the Photo Works, Nottingham. In addition to full particulars of developing, printing, enlarging, lantern slide making, etc., which the firm undertakes, it contains several good half-tone reproductions.

JOBBERS, LTD., 12, Paternoster Square, E.C., have just issued their 1904 catalogue of photographic requisites, which includes many good things. The principal novelty appears to be a series of hand and camera for photographic post-cards. These cameras are made to order, special plates, measuring $5\frac{1}{2}$ in. by $3\frac{1}{2}$ in.—the regulation postcard size.

THE New Magnetic Observatory.—A Scotch correspondent of the "Standard," writing one day last week, says it is intended to begin operations at once for the erection of the new magnetic observatory Eskdalemuir, Dumfriesshire, in place of the one at Kew. Representatives of the Government and the Duke of Buccleuch, from whom the land at Eskdalemuir has been bought, have visited the site, and May, 100 men are to be at work.

We have been informed that the business of photographic dealers, enlargers, lantern and cinematograph showmen, and X-ray operators carried on by Messrs. Williamson and Co., of Hove, has been purchased by Messrs. Sanders and Crowhurst, Opticians and Photographic Dealers, of 71, Shaftesbury Avenue, London, W. Messrs. Williamson and Co. will, however, continue to carry on the business of Cinematograph Film Makers at the Works, Wilbury Road, Hove.

CONCERNING the paucity of sales at the International Society's exhibition, a correspondent tells the following anecdote: "A very distinguished Impressionist artist was picked up by a successful popular painter and taken into his carriage. Said he: 'Can you explain why you should be making your thousands and driving in this old carriage while I am almost starving?' The popular artist pointed out of the window to a crowd, and asked what proportion of the crowd was intellectual enough to buy clever pictures like those of the Impressionist. 'Hardly any,' he replied; 'perhaps two or three.' 'Well,' rejoined the popular man, 'the clever ones buy from you; all the rest come to me.'"

ROYAL Institution.—On Tuesday, April 12th, at 5 o'clock, Professor L. C. Miall delivers the first of the three lectures at the Royal Institution on the "Transformations of Animals"; on Thursday, April 14th, at the same hour, Professor Dewar begins a course of three lectures on "Dissociation"; and on Saturday, April 16th, at 3 o'clock, Mr. Cyril Davenport delivers a lecture on "Mezzotints"; to be followed on the two succeeding Saturdays by lectures (1) Cameos; (2) Jewelry. The Friday evening discourse on April 15th will be delivered by Count Vay de Vaya on "Korea and the Koreans"; on April 22nd by Colonel David Bruce on "Sleeping Sickness in Uganda"; and on April 29th by Dean Robinson on "Westminster Abbey in the Early Part of the 17th Century."

MR. W. CLAYDEN, of Plymouth, gave a lecture on "The Carbon Process" before the members of the Devonport Camera Club on

March 31st. During the evening, Mr. A. J. Catford, the hon. secretary, reported that the arrangements for an exhibition to be held during Whitsun week were complete. The patron of the Club, Lord St. Levan, had offered a gold medal for competition in the open classes, and this, together with a silver medal offered by Dr. E. Symes Saunders, and sixteen silver and bronze plaques offered by the Society, made the award list better than in any previous exhibition held in the West of England. Lord St. Levan also promised, if in the neighbourhood, that he would attend the opening ceremony. Mr. Catford said the judges would be Mr. J. H. Coath, F.R.P.S., of Liskeard; Mr. H. R. Babb, Principal of Devonport School of Art, and Mr. C. E. Brittan.

DUTCH Art at the Whitechapel Art Gallery.—On Tuesday, last week, another loan exhibition was opened at the Whitechapel Art Gallery. This time it is a collection of Dutch pictures. The pictures shown are not all of equal merit, but the majority are of very high quality. Pictures of the Dutch School of the seventeenth century should be of special interest to photographers, inasmuch as so many of the subjects depicted—portraits, interiors, and studies—may well be dealt with by photography. In the collection will be found fine examples by Mauves, Maris, Israels, Bosboons, as well as some good Rembrandts. Since the exhibition was formally opened, it has been further enriched, for we learn that the Duke of Devonshire has lent his two fine portraits by Frans Hals, and Mr. Pierpont Morgan has also lent the superb portrait of the painter as a young man, by Rembrandt. By the way, many photographers who are now providing so-called "Rembrandt portraits," would do well to see some of Rembrandt's work; if they did, they would then see how widely different it is from what they produce under the name of "Rembrandt pictures."

THORIUM in Ceylon.—The Government of Ceylon determined last year to carry out a systematic survey of the economic minerals of Ceylon and to despatch specimens of the minerals found to the Imperial Institute for chemical examination and commercial valuation. Among the specimens thus received were those of a mineral existing in small black cubical crystals, and supposed to be uraninite or pitchblende. The specific gravity of the mineral was found to be 9.32, and analysis showed that it is clearly not pitchblende, since the percentage of oxide of uranium is only about 12 per cent., whilst the principal constituent is oxide of thorium (thoria), which is present to the extent of over 75 per cent., an amount far higher than that contained in any mineral hitherto examined. This mineral appears to be new, and Professor Dunstan has suggested for it the name of thorianite. Since it is radioactive it may prove an important source of radium or radioactive earths. A second mineral less rich in thorium has also been found, and careful explorations are now being made as to the extent of the occurrence of both in Ceylon. The discovery of two minerals rich in thoria, now so largely employed for the manufacture of incandescent gas mantles, may be of considerable commercial importance should they prove abundant.

ANCIENT Astronomy.—At a meeting of the British Astronomical Association, held on Wednesday, last week, at Sion College, Victoria Embankment, Mr. A. W. Maunder, Superintendent of the Solar Department at Greenwich Observatory, gave an account of ancient astronomy and the usage of the signs of the Zodiac. He fixed the date of the origin of the 48 constellations at about 2,800 B.C. From a number of Babylonian and Assyrian tablets used in connection with the earliest Greek records he came to the conclusion that about 700 B.C. there was a great development of the science of astronomy, and that the sign of the Ram in the Zodiac was then recognised as the leading sign instead of the Bull as before. Julius Cæsar fixed the beginning of the year shortly before the Winter solstice; the Hebrews' civil year began at the Autumnal equinox, and the Assyrians' at the Spring equinox. A letter was read from one of the German Observatories stating that it is intended to organise an expedition to Spain to observe the Solar Eclipse which takes place in August, 1905, and is visible in that country, and asking for the co-operation of the British Association in the expedition. The consideration of the letter was postponed.

BEN Nevis Observatory.—There seems to be a prospect that the high-level observatory on Ben Nevis will be kept going for some time

longer. It will be remembered that some time ago the Meteorological Council decided to close it on account, it said, of want of funds. But it should be borne in mind that the Council was never much in favour of this observatory, so that it received but little money from that source, and the money subscribed by the public did not amount to much. However, it is now stated that a generous donor has come forward with a sum that will be sufficient to keep the observatory on for the next three years, and now, it is said, Sir Herbert Maxwell's committee have agreed in recommending that more money should be granted to it, also that means be taken to organise the work to be done there, so that meteorological science may have the full advantage of the observations made there. It appears that, hitherto, this observatory has not been required to send daily telegrams to the Meteorological Office, so that there have been no means of testing whether the observations at Ben Nevis have any value in reference to forecasting the weather. This seems a little strange, seeing that the Meteorological Office have still something to learn in the matter of forecasting the weather, even for twenty-four hours in advance, as is frequently seen by the daily forecasts now issued. However, it seems that this is to be changed, as it has been recognised that before the Ben Nevis Observatory is discontinued it should be given the opportunity of showing what service it can render to meteorological science. Few of us, we think, will envy those who are engaged at the observatory at the top of Ben Nevis all the year round, and more particularly during the winter months. At no period can it be a cheerful dwelling.

TECHNICAL SCHOOLS IN GERMANY.—The latest of the series of reports on technical education in Germany by Dr. Frederic Rose, our Consul at Stuttgart, deals with technical schools for special branches of the metal industries, and may be regarded as a continuation of No. 601 on special schools and courses for mechanical engineering and electro-technics. The courses described in both reports belong to secondary or middle technical education, and should not be confounded with the higher technical instruction given at the ten great technical Universities, which has been described in previous reports in the series. The schools discussed in the present report "are intended to take the place of the apprentice instruction in the workshops of factories, and may, therefore, be regarded as an attempt to solve the problem whether for certain branches of certain industries with their highly specialised modern requirements apprentice instruction in the works themselves or in a special technical school with a combined theoretical and practical curriculum is preferable and more productive of practical and profitable results." The Consul discusses the respective advantages and disadvantages of these two modes of early technical training at some length, and then describes in detail the system of training at twelve schools in various parts of Germany, nearly all founded in quite recent years, and all dealing with metal industries. Of these three are devoted to steel and iron ware, one each to bronze, copper, sheet metal, and precious metals, jewellery, while three are given up to clock and watch making, and two to general mechanical and artistic ironwork. In addition to these schools, Dr. Rose states that combined theoretical and practical instruction is given on a complete scale by the administrative bodies of the State railways, and by many large industrial establishments.

ILFORD COMPETITIONS.

THIS competition marks the completion of the twenty-fifth year of the manufacture of Ilford plates, which have deservedly achieved world-wide renown. We have no doubt that details of the competition will be awaited with the greatest eagerness, and that a very large number of entries will be secured. The production of a perfect negative has been authoritatively termed a combination of art and science; we await with no inconsiderable interest the results of a competition which will bring together a collection of clichés in which these qualities are manifested. Print competitions galore abound; seldom, however, are prizes offered for what is after all the very base and foundation of the photographic art: the negative. Hence the Ilford Competition is invested with unique interest.

Correspondence.

- * * *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

THE VERANT.

To the Editors.

Gentlemen,—I was much interested in the theoretical explanation of "The Verant" which appeared in your issue of January 8th. By the time you receive this letter you will probably have further information about it, and I shall be much obliged if you will kindly answer the following questions:—(1) Is the stereoscopic effect produced by viewing an ordinary photo with a single lens Verant, or two prints from the same negative placed side by side viewed with a double lens Verant, equivalent to that of a stereoscopic slide, viewed with an ordinary stereoscope? (2) Will it be of any advantage to use a double lens Verant for viewing a stereoscopic slide instead of the ordinary form of stereoscope with half lenses as now used, and, if so, is the Verant made in the enclosed form with a ground glass screen for viewing transparencies, size $6\frac{1}{2}$ by $3\frac{1}{4}$? (3) From whom can the Verant be purchased in England?—I am, sirs, yours faithfully,

H. R. HEARSON.

Shanghai, February 20th, 1904.

[A note on this subject will appear in our next.—Eds. B.J.P.]

AURORA AUSTRALIS.

To the Editors.

Gentlemen,—On page 267 you say "as far as we can gather, this beautiful thing has never been photographed." Unless my memory is playing me a trick, I have seen a photo of the aurora, exhibited by Lieutenant Shackleton, R.N., who was invalided home from the South Polar Expedition. We had the luxury of a lantern lecture from him in this village a short time ago, and among the number of beautiful photos, one, if not two, were of the aurora, so I believe, and he told us that it showed beautiful tints, unless again my memory is playing me false.

We had this luxury owing to Lieutenant Shackleton being a cousin of Mr. W. A. Bell, of Pendell Court, and no one who was present will ever forget that lecture. He told us very little about himself, but he was one of the three men who have been furthest south, and how he ever got home is a tale that one would like to hear, but none of them will probably say much about it.—Yours truly,

JARVIS KENRICK.

Pendell, Bletchingley, March 31st, 1904.

CHROMATIC RADIOGRAPHS.

To the Editors.

Gentlemen,—I have been greatly interested in your "Photographic Almanac, 1904," more especially in your paper upon the Eburneum processes, because it touches upon a stripping process which I am searching for, so as to enable me to overcome the combination between paper and nascent silver.

For the past year I have been studying the effect of radiation upon chloride of silver, and have produced over 1,000 examples of what I call "Chromatic Radiographs," three samples of which I enclose. The ordinary commercial photographic printing paper is used, but I find if I could obtain a gelatine stripping film I could obtain much better results, and also if I had any ready means of controlling the quantity of chloride of silver in the film. There is an ultimate strain effect, and an arrested strain effect, and my method of arresting is to expose the back of the photographic paper to the radiator. With soluble and insoluble gelatine film in one piece, I could draw by diffusion all the silver from the face to the back, and then remove the back film of gelatine. This would lead to being able to take a positive on gelatine, and fix with my radiator by diffusion in the dry state without touching liquid. Then the photo chloride picture on the front face could be thrown into the ultimate or stable photo chloride of Ag. by exposure to sunshine and thus enter into a stable condition of silver. At present all photos are arrested conditions, liable to

ge, whereas a chloride of silver exposed for two hours to bright
hine is not liable to change after reaching the ultimate strain. It
e same with my chromatic radiographs. The arrested strain reverts
alls back, whereas ultimate strain does not do so. Professor
ley explains this in your Journal. Can you kindly put me in the
of obtaining what I search for. The stripping films are described
Thorpe's Applied Chemistry," Vol. III, p. 216.—Yours truly,
s Tours, St. Clement's, Jersey, ARCHD. C. PONTON.
Channel Isles.

We doubt if such stripping films are now commercially obtainable.
os. B.J.P.]

TELEPHOTO DIAGRAMS.

To the Editors.

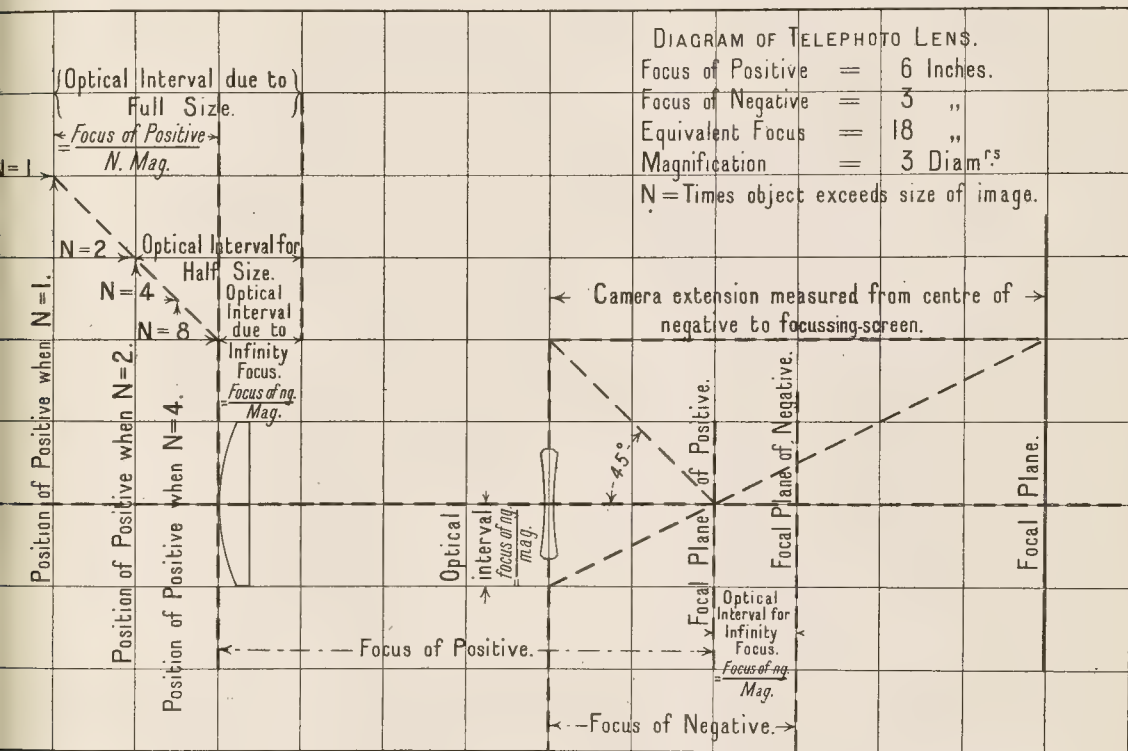

Gentlemen,—In your issue of March 27th, 1896, p. 200, you pub-
d a diagram of a telephoto lens. I have recently improved this,
ting it to use on squared paper, and also extending it to show the
cal interval required to give images in various proportion to the
inal. In the case of near objects (when using a large stop) the size

PSYCHIC PHOTOGRAPHS.

To the Editors.

Gentlemen,—Respecting the late exhibition of the above, it is to
be regretted that your representative did not make himself known to
me, as I should have been glad to have given him some information
on the subject, which is an intensely interesting one, and of the
highest importance.

The collection consisted of about three hundred photographs, many
of them taken by amateurs, and with over a dozen different sitters,
and evidence of this magnitude is not to be dismissed with a few
sarcastic comments from one who has evidently not made any study of
this particular phase of photography—"Some of these, we have no
hesitation in saying, are taken from pictures, and in nearly every case
the face of the ghost is framed in stiff, new muslin." This is a
serious charge, but the absurdity of these statements betrays the
prejudice of the writer, and I will forfeit a sovereign for each and
every photograph exhibited that he can prove to be taken from a
picture. As to the "stiff muslin," this is simply an aura which the
spirits sometimes find it necessary to envelop themselves with when

the object may be calculated from the photo taken if the optical
val be noted. In constructing the diagram the focus of the
ive can be left over for a time. That of the negative and magnifica-
is all that is required to construct the portion of the diagram to
right hand. The magnification is the equivalent focus of the
combination divided by that of the positive of whatever length may after-
is decided on. I think it important to make this clear, as the
magnification is sometimes applied to the focus of the positive
led by that of the negative—in other words, the magnifying power
combination if used as a Galilean telescope. The optical interval
finity focus being calculated by dividing the forms of the negative
the magnification the construction of the diagram will be apparent.
the focus of the positive now being fixed upon, it is only necessary
etermine its movement to give an image 1-nth of the size of the
nal. This can be found by dividing the focus of the positive by
mes the magnification. This being calculated for full size, the
movements are then obtained by construction, and the diagram
s also the total optical interval due to any selected value of n.—
CHAS. LOUIS HETT.

being photographed as a protection from the human magnetism, which,
under certain conditions, has a dematerialising effect. In nearly
two hundred of the photographs, which comprised spirit forms, faces,
flowers, birds, and lights, no aura had been necessary, while some of
the pictures showed several faces, and in one which was taken in
Washington, appear no less than twenty-four, including my own
mother. This is the most wonderful photograph that I have ever
seen, and is from one of eighteen negatives taken at one sitting, seven-
teen of which exhibited spirit manifestations.

It is desirable to say that in most instances all proper precautions
were taken against any possibility of fraud, and on many occasions I
was accompanied by a clairvoyante, who wrote down a description of
the forms as they appeared. Some of the promises were given in
Canada and fulfilled in London and Washington, and though some of
the great ones of the past have taken this means of showing their
continued interest in those still in the mortal, yet the large majority
were relatives and friends of the sitters or unknown to them. My
little niece has been taken with me four times, and each in a different
position. This effectually disposes of the assertion "that it

would be extremely easy for any photographer to produce the same effects."

Hundreds of aching hearts have been made glad by the appearance on the plate of some loved one from "the other shore," and as soon as the public generally begin to understand this possibility, then there will arise such a demand for cameras and their accessories as will astonish the whole trade.

At the present time I know of more than half a dozen amateurs who occasionally obtain psychic markings, lights, or faces on their plates, sometimes with a camera, and at other times by simply holding the plates in their hands; and as there have been many cases where professional photographers have taken invisible sitters, may I suggest that it would be of great interest to have details of any such instances recorded in your columns?

It is now above forty years since spirit photographs were first known, and ten years ago your late esteemed editor, Mr. J. Traill Taylor, convinced himself by a long series of experiments, and the Rev. H. R. Haweis courageously held an exhibition at his own church.

We have far better evidence before us in the present age, when it is difficult to take up a newspaper without finding some reference to the "psychic," or "occult." Photographers, of all people, should learn that a new world is open to their view, and though at present this phase of mediumship is very rare, yet no doubt in the near future many earnest students will be able to develop the gift, and prove that "there are more things in heaven and earth than are dreamt of in your philosophy."—I am, yours, etc.,

April 4th, 1904.

H. BLACKWELL.

[Mr. Blackwell has been good enough to call upon us and exhibit a large number of negatives and prints in support of his claim that the somewhat abnormal results criticised in these pages, were produced by direct photographic agency. Of Mr. Blackwell's bona-fides in the matter we ourselves have no doubt; he is a gentleman of the highest probity, and a personal acquaintance of our own of some twenty-four years' standing. Without any other object than that of honest investigation, he has devoted a great deal of time and money to the study of psychic photography. He is, besides, an expert amateur photographer. We also understand that he is not unwilling at an early date to address a photographic society on the subject of his experiences. While at first we were inclined to close the correspondence at this point, we think, upon reflection, that the cause of truth will best be served by keeping our columns open for a few weeks longer to those of our readers who may feel inclined to give us the benefit of their experiences in psychic photography. We do not, however, invite anonymous letters on the subject.—Eds. B.J.P.]

THE METRIC SYSTEM.

To the Editors.

Gentlemen,—I much regret to find a bad blunder in my last letter. A treacherous memory failed to remind me that a standard millilitre cannot possibly be smaller than a cubic centimetre at the same temperature (being in fact always larger) and that the figures based upon the table of equivalents must therefore be wrong. As the table only shows "legal," and not actual, equivalents, it is impossible to find from it the weight of a standard litre at 62 deg. F. Things equal to the same thing are not equal to one another in the table, which fact I entirely overlooked. It appears that the litre at 62 deg. F. is really rather less than a gramme under weight, hence the difference is even more "hair-splitting" than before, but this in no way upsets the fact that the discrepancy has caused the introduction of the conventional litre and has complicated the metric system. It has also caused confusion as to the meaning of the term cubic centimetre, which is now applied indifferently to the conventional and standard millilitres as well as in its proper sense. Mr. Tennant has fallen into the same error with regard to this conventional litre as certain other metrical advocates. It is not simply a foolish British invention due to the Royal College of Physicians. The Superintendent of the Standards Department of the Board of Trade has stated that in adopting the litre graduated at 60 deg. F. we have only followed foreign practice. Further, a man of science, who is not a doctor, informs me that measures graduated at 15 deg. C. are commonly used, hence they are evidently not "repudiated by all men of science." It is also worth note that such measures, verified in Berlin, are the only verified "Standard" measures listed by one of the best known English dealers in chemical apparatus. As specific gravity bottles are also graduated at normal temperatures it does not appear that inconveniently low temperature standards are now really necessary. In any case the three different temperatures of the metric system are confusing.

Mr. Tennant's "squaring" problem does not prove his case. By chance one of his metric figures is a simple 12, and if another figure had appeared the case might have been very different. Further, the usual run of such problems include feet as well as inches, and if 1-in. is the limit of error metric dimensions then involve three or four

figures, when there is at once a most distinct advantage on the side of the English measures.

To deny that it is easier to find $3\frac{1}{4}$ per cent. on £67 than on 67 dollars is equal to denying an obvious fact. With the dollars you multiply by 3.5 and cut off two figures, and you have the answer in dollars and cents; with the £67 you multiply by 7 and cut off one figure, when you have the answer in shillings, pence, and fifth of a pence. This is obviously shorter, as there is one figure less in the multiplier, and with all ordinary rates there is nearly always a saving of one multiplier with the English money. Mr. Tennant's clumsy method is, of course, the wrong one for this type of sum, though it might be the right one for a sum of a different type. There are always half-a-dozen different methods to choose from, and the right one is the shortest.

With regard to my suggestion that a decimal system based on an existing English unit would be readily acceptable, it is interesting to see that the Central and Associated Chambers of Agriculture, on March 29th last, passed, by a large majority, a resolution to the effect that the Chamber would welcome a measure improving weights and measures by the introduction of a decimal system, "but not by adopting a metric system which has no affinity with our existing denominations used in trade or commerce in the United Kingdom." It is worth noting that we have the basis of a good system in the fact that an ounce fluid is equal to an ounce avoirdupois and to the cube of the 'centh-part of a foot, within an error of less than $\frac{1}{2}$ per cent. The decimally divided foot is already a common measure marked on two-foot rules, and a system worked out on this basis would include many of the best of our present units, and could be used in unison with certain nondecimal units that we cannot part with.

I see that "Free Lance" in your issue of February 19th refers to "the clumsiness of the metric system for general use," and to the fact that English measures "lend themselves to ready calculation and subdivide far more readily." He thus very aptly describes two facts which alone are enough to condemn the metric system for general use in this country. The system is clumsy because its scheme is too simple for our intricate requirements.

Mr. Tennant suggests that manufacturers find no difficulty in supplying things to strange weights and measures when it is worth while. Just so. The weights and measures difficulty is a very small matter in the great majority of cases, therefore, why should we be compelled to go to the expense and inconvenience of altering them to please only a small minority of our customers? Our export trade in metric countries is only about 41 per cent. of our whole export trade, and only 15 per cent. of our whole overseas trade, and only a very small portion of that 15 per cent. is affected by the metric question at all. What we want is a system convenient to ourselves first, and to the majority of our customers next. The minority may not like it, but charity should begin at home. Again, Mr. Tennant says that the export of cameras is hindered by heavy duties. Other exports are hindered by the same cause, but the usual metrical argument is that our weights and measures are the cause of the trouble, and therefore, we should alter them. Evidently Mr. Tennant does not see eye to eye with the reformers in all respects.

With regard to the protective effect of our system the protection is not so much against fair competition on the part of foreign manufacturers enterprising enough to master our measures; but against unfair competition. Any natural surplus stock held by the foreign manufacturer, being in his own measures and not in ours, cannot be thrown on our market at under-market prices; while the creation of an artificial surplus in our measures is a losing game. This, of course, only applies to cases in which measure or gauge is of real importance. In a number of cases it is of no importance whatever. The trade that would be most seriously disturbed by compulsory metric measures is the building trade, which for some time would be completely disorganised. This would necessarily increase the cost of building and directly or indirectly affect all pockets and purses, photographic or otherwise, through the media of rates and rents.

An apology is due to you, gentlemen, for the length to which this discussion has extended. I have felt bound to do all I can to correct the exaggerated claims made by worshippers of decimals and the metric system, which have been of such a nature as to mislead people into thinking that decimals are an infallible cure for all present complaints, but I have no wish to pursue the subject further in this journal. Thanking you for the space you have allowed me to occupy and regretting there has been so much of it.—I am yours, etc.,

April 2nd, 1904.

C. WELBORN PRER.

[The correspondence on the Metric System has gone to quite sufficient length, and we here terminate it. Without on the present occasion arguing the pros and cons of the subject, we agree with Sir William Abney, who some years ago, when speaking on the subject, said it was a very difficult thing to accustom persons who habitually thought in grains, ounces, inches, and feet, to think in cubic centimetres, and millimetres. Parliament can do, it is said, everything but convert a man into a woman; we are equally of opinion that it will find it just as difficult to supplant the existing system of weights and measures, unscientific though it may be, by the undoubtedly scientific but unquestionably alien metric system.—Eds. B.J.P.]

Answers to Correspondents.

* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

W. Oakley, Sussex Cottage, Sholing, Southampton. Photograph of Troopship "Assaye" after Collision.

Hunter, The Studio, Port-Glasgow. Two Photographs of Provost H. McMaster. Keeping, 94, Paris Street, Exeter. Two Photographs of Hallsands, Devonshire.

F. J. Clegg, 7, Onborsley Road, Birmingham. Two Photographs of the Rev. T. Tozers.

Cherry, 38, Castle Street, Cirencester. Photograph of the Church and Market Place, Cirencester. Photograph of the Police Station, Cirencester. Photograph of the Barracks and Park Gates, Cirencester.

A. Horsburgh, 4, West Maitland Street, Edinburgh. Photograph of Hon. C. M. James.

Penske, 99, St. John's Hill, New Wandsworth, London, S.W. Photograph of the Royal Masonic School for Girls, Wandsworth Common.

FLASHLIGHT COMPOSITION.—T. W. S. says: "Kindly tell me if people using flashlight powder require to have a licence under the Explosives Act." In reply: No, unless the powder is stored in quantity.

FIXING BATH.—M. BELL asks: "Is a 5 per cent. solution of hypo. sufficiently strong for the fixing of P.O.P.?" In reply: No; double that strength is rather weak, unless a pretty long immersion is given.

FORMULA WANTED.—E. HADLEY says: "Kindly give me a developing formula that appeared in the 'Almanac' some years ago for plates, published by Clement J. Leeper?" In reply: We must trouble our correspondent for a more definite date than "some years ago." We have referred to the "Almanacs" for the past seven years, and do not find the formula.

REQUIRE.—You should, surely, be better able than ourselves to judge if your establishment is over-staffed. We should think that it was not. The employees are certainly not overpaid, and the hours none too short. Your prices are rather low, but with the turnover you mention we do not see how you can lose money over the business unless the rent and taxes are abnormally high.

PRO. CASES.—J. E. GUBBINS writes: "In the 'B. J.' of the 25th ult., p. 247, bottom of first and top of second column, you say, 'One extensive manufacturer at Bow,' etc. Will you kindly tell me the address and what he makes? The case would suit for hypo., and I want to buy some." In reply: The address is Messrs. Boake and Co., chemical manufacturers, Bow, London.

NUMBER OF PHOTOGRAPHERS.—J. C. HARRISON asks: "Can you give me the number of professional photographers in England, Scotland, and Ireland and adjacent islands?" In reply: We cannot. The only way to get the numbers is to consult the last census returns. You will be able to get them, we believe, from the King's printers, Messrs. Eyre and Spottiswoode, East Harding Street, E.C. We do not reply to correspondents by post.

TREAT OF RESIDUES.—HAD asks: "Will you inform me if my conception of receiving a percentage of silver waste from your employer is and has been a standing rule in the photographic trade? I may here state I have made inquiries, and there seem doubts on same. The waste, I may say, is all wet plate work." In reply: We have never heard of employees claiming a share of the residues, and we do not see that they have any

claim. So far as we know, there is no trade custom in the matter.

PAPER FOR X-RAY WORK.—E. T. W. says: "On p. 802 of 'B. J. Almanac' a new bromide paper for X-ray work is mentioned. Could you tell me the exact name of this paper, and where it can be obtained in England? Also what English papers, if any, would give good results with X-ray work?" In reply: The address of the makers of the paper is given in the article. Probably the Rotary Photographic Company, which is the English branch of the firm, will supply the paper. Any bromide paper will answer for the work, whether English or German.

ENLARGING.—LUX says: "I enlarge with condenser and 50 c.p. electric incandescent light, but as soon as I attempt to stop down I get rainbow circles on my screen. Please say how am I to avoid this. I may say (even if it suited my purpose) to alter the distance between lamp and condenser that has no effect." In reply: If you cannot alter the position of the condenser, we should advise you to work the lens at full aperture. The lens named by you will cover well with its full opening.

COPYRIGHT QUERY.—ANDION says: "I have two photographs I want to copyright in the shape of a postcard. The two pictures will appear on one card, longways, and will cover the card. In so doing must I copyright both pictures, or will one fee be enough to cover the safe registration of both? Also, as both prints will be titled and dated, must the prints bear this before copyrighting them? Your assistance will oblige." In reply: Each of the pictures should be registered. It is not necessary that the pictures be titled before they are registered.

A BUSINESS QUERY.—PRENTICE asks: "(1) Is an apprentice photographer a professional photographer? (2) When a professional photographer places an order with any of the large wholesale dealers, is it an understood thing that he gets a special discount, or does he have to ask for it?" In reply: Yes; if he follows his business when he is out of his apprenticeship. (2) Different dealers have different terms as to discounts. Your master will enlighten you as to those of the firms he deals with during your apprenticeship.

ENAMELLING PRINTS.—G. S. GALLOWAY asks: "Could you kindly give me the title and publisher of any good book on enamelling C.C. prints; or any more general work which deals in detail with that process; or any other place where I could get information on the subject?" In reply: There is no book devoted to enamelling collodio-chloride prints, and none is required. The prints are simply enamelled as other prints are. So much has appeared on the subject in back volumes of the JOURNAL, that we should have imagined that every one was familiar with such a simple thing as enamelling prints, whether C.C. or others.

POSITIVES DIRECT.—J. KEANE asks: "Will you please inform me if there is any means of taking a positive on bromide paper or glass direct in the camera, or can I reverse the image by development? If so, please give formula." In reply: We know of no successful method of taking positives on bromide paper direct in the camera. On plates, by giving a short exposure, and then whitening the image with bichloride of mercury, and backing up with black varnish, fairly good results may be obtained, but not equal to those obtainable by the old collodion process.

RESIDUES.—HELIO asks: "Can you tell why silver print washings remain turbid?—it takes fully two weeks before they will precipitate after large, old oil-barrel is filled up. I have tried more or less salt, also sulphuric acid and hydrochloric acid, but the washings will remain turbid for so very long a time. Our town water is hard and chalky. Can I hasten the precipitation?" In reply: If there is very little silver in the water it will take a long time to subside, owing to the fine state of division the chloride is in. Try using hydrochloric acid in place of the salt, and well stir up the contents of the barrel after the addition.

PICTURE POST CARDS.—W. M. asks: "Can you tell me whether there are firms who publish picture post cards of suitable subjects from photographers' negatives, paying the photographer a percentage or royalty on copies sold? I have some animal studies, but do not wish to sell the negatives outright." In reply: There are several firms that purchase negatives for picture

post cards, but we do not know of any that deal with them on the lines mentioned. You might, however, write to the Rotary Photographic Company, New Union Street, E.C., or Messrs. Wyndham and Co., Acton, W.

STUDIO.—CLAY AND LACY write: "We wish to convert a room into a studio. The dimensions of room are as follows: 20 ft. long by 10 ft. wide. Roof concave, slanting from 15 ft. to 7 ft. at the sides. People adjoining object to us making window for north side light. Can you suggest any other method of lighting to answer purpose?" In reply: It seems to us that, as you cannot have a side light, you will have to be content with a top one—bring that as low as you can. A top light in so small a studio will be somewhat difficult to work, but there appears to be no help for it.

CAMERA OBSCURA.—NERO says: "I am thinking of building (in an amateur way) a camera obscura. I am not quite clear as to the arrangement of lens, prism, reflector, etc., at top. If you can give me details of this I should be much obliged?" In reply: This is a very simple matter. Fix in the top of the building, so that it can be revolved horizontally, a mirror at an angle of 45 deg., so that the image is reflected on to a lens fitted in the ceiling of the room. In the room, at the focus of the lens, place a table with a whitened top to receive the picture. Most of the old works on optics give a diagram of the arrangement.

DAMAGED PULP SLAB.—E. A. JOHNSON (Algiers) says: "I have got a pulp slab for glossing P.O.P. prints which, through constant use, has lost the high polish it originally had. I should be much obliged if you could give me instructions for restoring it, if it can be done. I have tried beeswax and benzine, which acted all right for a single batch of prints, but would not stand a second." In reply: We are afraid that you will not be very successful in re-polishing the slab. You might, however, try putty powder or rouge. But the beeswax treatment is not much trouble, even if you have to treat the slab with it every time you use it.

LENS QUERY.—BUSY BEE says: "I have a 12 by 10 extra rapid lens, and thought I would try it for portraiture, but find it not much better than a 10 by 8 —'s rapid rectilinear. Does the fact of it being a 12 by 10 make it better for half-plate work in studio than a good portrait lens (half plate) as regards definition and quickness in exposure? Which would be best, half-plate portrait, or 12 by 10 mentioned?" In reply: The large lens, by reason of its greater focal length, would cover the half plate better than a half plate portrait lens would do with its full aperture. But the latter would have about four times the rapidity of the former.

CLAIM TO ESTATE.—H. M. says: "May I ask the following question? A few months ago a photographer in the suburbs of London died, leaving a house full of good furniture, also valuable photo. apparatus and a banking account. Having no father or mother, the eldest of the family (a sister) claimed and took the lot, but did not pay any of the creditors. Am I right in saying all the creditors should have been paid first, then what was over equally divided between the rest of the family?" In reply: The creditors should certainly be paid before the estate is divided. You had better consult a solicitor on the matter.

STUDIO BUILDING.—BLACK BOY says: "I am about to erect a studio, and enclose herewith a rough sketch of the accommodation at my disposal. I wish to know which would be the better way to build the studio—against the southern wall and facing north (approximately) or against the western wall and facing the house. If the studio were built with the northerly aspect, there is a window at A which could be enlarged into a doorway, giving extra room between the camera and sitter if necessary. Which system of glazing do you think would be the more useful, single slant or the usual top and side light?" In reply: If the north light is unobstructed, by all means build the studio against the southern wall. As to the system of glazing, it is quite a matter of opinion as to which is the better. Both systems are good.

LENS QUERIES.—LEX asks: "1st. Do you consider Beck's bi-planat lens, as per enclosed illustration, good for general portraiture

(studio work)? 2nd. No. 6 on accompanying list is recommended me. Can you tell me the distance required for a full length of adult with it from lens? 3rd. Will it work as quick as an ordinary portrait combination and give equal results? 4th. Would you say as to your knowledge of the portrait lenses by —, as advertised in your year book, page — for 1903? 5th. Will you tell me the mechanical form of arrangement for heating hollow roller by spirit when gas is available?" In reply: 1. Yes. 2. About 18 ft. 3. The same will be somewhat slower than an ordinary portrait lens. It will require about double the exposure. 4. We have had no personal experience with the lenses named. The firm, however, is a good one. 5. Better write to the maker, as you do not say whose burnisher it is.

SELECTION OF APPARATUS.—INVALID writes: "I want to furnish myself with a $\frac{1}{2}$ -plate camera and lens and the strictest necessities for outdoor photography, but as my knowledge of such articles is very limited, and also my means, I wish you would kindly instruct me: (1) What kind of camera and lens to choose for outdoor and occasional indoor work, and, if compelled to buy them second-hand, how to test them; (2) what is the best contrivance for changing plates without a dark room; and (3) from what book could I gather the most information about outdoor lighting." In reply: (1) An ordinary outdoor camera, you will find many different kinds advertised in the "Journal" and the "Almanac." A lens of the R.R. type will be the most useful for general work. You can test the apparatus by taking one or two pictures with it. If you buy a second-hand one, or, perhaps, the better way would be to get a photographer to test it for you. (2) A small, portable dark tent or box. (3) You will find Robinson's "Letters on Landscape Photography" useful.

VARIOUS QUERIES.—T. COUSIN asks: "Fluorotype Process (1) How to prepare fluuate of soda, as I find difficulty in obtaining it, and do not see it mentioned in any of the books on chemistry. Chromotype Process—(2) Strength of the nitrate of silver solution in washing over the exposed print, and also the strength of the neutral solution of the chloride of gold in the modified process. Monckhoven Silver Cyanide Intensifier—(3) Have intensified a negative with same, but it has altered the negative to a considerable degree. As I wish to bleach the negative in mercury and re-develop with ferrous oxalate, please say how to remove the silver cyanide and restore the negative to its original condition. Furnell's Developer—(4) In this the preservative is nitrate of soda. It gives negatives of a chocolate colour and quick printing. The solution itself keeps good a very long time. The formulae appeared in the first edition of 'Wall's Dictionary of Photography,' but I have not a copy of same. Please give me formula." In reply: (1) Saturate hydrofluoric acid with soda and then evaporate to dryness. You will do better, however, to purchase the salt. It may be had from such houses as Hopkin and Williams', Cross Street, Hatton Garden. (2) The strength of the solution is not very material, but it must not be strong. (3) If you have made the negative too dense it may be reduced with a weak solution of hyposulphite of soda. (4) Some reader may be able to oblige; we have not a copy of the book referred to.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Chemicals and their formulæ.

The theory of the constitution of a compound that is capable of developing the latent photographic image has been reduced to such luminous simplicity by Messrs. Lumière and Seyewetz that a mere inspection of the formula of a particular compound enables a safe prediction to be made as to whether it possesses developing powers or not. It is the popular idea that the same certainty is to be found among the dye-stuffs of modern creation, yet so far from being the case that Prof. Meldola, speaking of particular class of dyes, says: "With the exception of . . . for which a probable formula is given, not one of these new compounds has even an empirical formula assigned to it. We have here, in fact, another illustration of the well-known principle that technology is often in advance of pure science"—which is a very nice way of saying that "rule of thumb" is often in advance of laboratory learning!

Public Recognition Opticians.

We learn from the "Photographische Correspondenz," that the Town Council of Vienna, at the suggestion of the Photographic Association, have named one of the streets "Petzvalgasse," after the well-known inventor of the portrait lens. Petzval was not only the first photographic optician of note, but his work was so thorough that now, after more than fifty years, his portrait lens still remains the favourite of the professional photographer, notwithstanding the many innovations of the last decade. Although Petzval's reticence has been adversely criticised, much might be said in his defence. The practice of

opticians to protect by patent the right to manufacture lens constructions they have invented and calculated at the cost of great mental strain, differs only from it in degree. Yet, who but those that are devoid of respect for the adequate remuneration of mental work, through the material products embodying its results, would find fault with the optician for availing himself of the protection given by the patent laws. In recording the fact of this honour, bestowed upon the deceased optician of Vienna, it may perhaps be interesting to remark that two other modern opticians have been similarly honoured. In Munich there is a Steinheil Strasse, and in Jena a Carl Zeiss Strasse.

* * *

Pirates and Coiners.

The police have lately had the good fortune and the cleverness to make two very important seizures. They have come upon a coiner's den, not of the usual humble kind, but a regular factory for turning out spurious money with a good "ring" to it, in large quantities. And they have also spotted a printing establishment whose apparent business it was to supply pirated music to the itinerant vendors who sell it in the streets. Not only was the printed music seized, but also a large number of photo zincographic plates which produced those printed sheets, plates which must have cost many hundreds of pounds to prepare. We are sorry that photography should have been put to so base a use as this, but it represents such an easy and cheap method of duplication that its employment was only to be expected in the hands of dishonest men. The law as to coining is about as severe as it can be, and the judges will have no difficulty in meting out punishment to the guilty ones, but we doubt very much whether the illicit printers and publishers will get their deserts. To our mind, the crime of robbing a man of the fruits of his brainwork is quite as heinous as that of making spurious shillings, but one happens to be an offence against the State, and the other is only against the individual. Men have been hanged, drawn, and quartered for piracy—but not for piracy of music—and as lately as the year 1835 a man was executed for coining. We are more merciful to our criminals now, but there is too often a great disproportion between the punishments inflicted for different crimes. It will probably be so in the cases now under consideration.

* * *

Exposure Tables.

Many amateurs will be glad to learn that the firm of C. P. Goerz is distributing gratis in Germany an exposure table worked out by one of their calculators, Herr W. Zschokke. It is printed on a stiff card, and easy to use because the series of factors expressing the conditions of the exposure are low numbers. Knowing the enterprising character of this

firm, we should be surprised if these tables are not distributed free to those who may wish to have them here in England. From the particulars given in the "Photographische Chronik" we are struck by the resemblance the tables bear to the well-known Hurter and Driffield system, excepting the speed standard of the plate. We are surprised that Herr Zschokke should have adopted the antiquated, unreliable standard, if such it may be called, of 25 degrees Warnerke. But as our best plate-makers now give great attention to the uniformity of the speed of their products, it will be an easy matter for the amateur to estimate a factor corresponding to the brand he favours. The Zschokke tables consist of factors. The first may be looked upon as the same as the H. and D. curves for the sun's altitude. The second corresponds with the H. and D. classification of the different characteristic kinds of light, and may be said to be identically the same. The third table gives factors for the ordinary classes of subjects. The fourth table expresses the speed of the plate in degrees Warnerke or degrees Scheiner. The fifth, the fractional value of the different stops of the lens. The product of the five factors is the exposure, expressed in time, which should be given to the plate. We know photographers who have used the Hurter and Driffield system for years and found it surprisingly correct for plates, which have been correctly marked according to the standard. The tables are more portable than the Actinograph, and should, therefore, be a welcome gift to the amateur photographer.

* * *

Another Aspect of the Patents Question.

We once knew a manufacturer of a kind of wire-netting, out of which he made a large income, he being the only maker who had worked the process to a successful end. He was, however, as the process was a secret one, afraid of some one getting the better of him in the matter of patents, and, eventually, he consulted a Quaker friend and confided his troubles to him. "Does any one know how to make it but thee?" he was asked, and replied in the negative. "Can any one find out how to make it?" "No, I think not." "Then, do not thee take out a patent, and tell everybody thereby how it is done," was the oracle's dictum, and it was adhered to with success. It is, however, a poor rule that will not work both ways, an old proverb tells us, and on this rock of secrecy versus patent a most promising modern vessel was wrecked. According to Prof. R. Meldola, F.R.S., the first member of the thiazol or thiobenzoyl colouring matters was introduced into commerce by Prof. Green, under the name of primuline (our readers will remember the photographic printing method with this compound as the main factor). The monopoly conferred by the right of discovery of this important compound was lost to the firm in the laboratory of which the discovery was made by the adoption of the short-sighted policy that a new product could be protected as a trade secret. Within a year of its introduction the Germans had found out its chemical constitution, and were manufacturing it, and a German firm actually obtained patents for producing it in this country as well as in Germany! The inference is that Prof. Meldola's advice would be to patent, and that the old Quaker we referred to was wrong in principle. There is, of course, a keener competition nowadays among rival chemists than ever has been the case, either as regards prices and the introduction of novelties, or the perfecting of processes. Yet it is not so very many years ago that a laboratory spy in the guise of a workman was discovered taking observations by his fellow-workmen at a coal-tar-dye manufacturer's works, a self-betrayal that cost him dear, as he was promptly tarred and feathered.

The N-Ray Mystery

We have already placed on record difficulty, or, rather, the impossibility experienced by many non-Continental observers of seeing the Blondlot rays at all, not to speak of classifying them, observing their indices of refraction and so on. The current number of "Nature" furnishes still another example of this impossibility of verifying M. Blondlot's discovery, in the form of a letter over signatures of John J. McKendrick and Walter Colquhoun, Physiological Laboratory, The University, Glasgow. The experiments were made with the help of seven observers, including five doctors, one student, and one laboratory attendant. Under a special code of signals they called out whenever changes were visible in the screens; and, unfortunately for the theory, when the changes did occur they were not preceded or accompanied by any muscular commotion. The observers were then told to look through the screen, as it were, into the distance beyond the bright spot—to focus the eye for infinity, to use a well-understood photographic term. They reported no changes in brightness, though brightness did follow when the observer touched the back of the screen. "How is it," the writer asks, "that M. Blondlot and many of his compatriots increase of brightness under conditions in which we see none?" They conclude by what we think we may agree to describe as a nice way of putting things: "Can it be that the mental condition of some observers in a state of expectancy reacts on the intrinsic muscles of their eyes, and thus they see what they think they should see?" We should add to this our opinion that if a ray can be divided into its constituents, after the manner we described last week, some of the first refractions ought to be powerful enough to act upon a sensitive dry-plate, and until we have an image fixed in that manner there is so much mystery surrounding the whole of the production of these one-sided phenomena that incredulity will characterise the reception in scientific circles outside those of the Académie des Sciences.

* * *

New Colour Sensitisers.

Our readers will doubtless have noticed that two very important colour sensitisers have recently been placed at the disposal of photographers. We refer to Orthochrom and Pinachrom. They seem destined to play a very important part in colour photography and some notice concerning their use, by Dr. E. Koenig, which has appeared in the "Photographische Correspondenz," will be found of value by those who wish to try these new sensitisers. They refer especially to Pinachrom, but Dr. Koenig remarks that practically the same results were obtained when using Orthochrom T. It has generally been found that dipped plates give better results than those which are sensitised by adding the dye to the emulsion. Those who require plates of the highest rapidity, therefore, usually sensitise them by dipping. To ascertain the best conditions for using Pinachrom, Dr. Koenig made a series of experiments, using the dye in various degrees of strength, and varying the time of immersion. It was found that a bath of 100 parts of water, 1 part of ammonia, and 2 parts of Pinachrom dissolved in 1,000 parts of water with four minutes' immersion, gave the maximum sensitiveness for red. The use of more dye does not add to the effect, and tends to produce fog. An increased quantity of ammonia gives rather greater sensitiveness, but some plates cannot stand it. Experiments were also made to ascertain the number of plates which may be dipped in the bath. 200 c.c. of water, 2 c.c. of ammonia, and 4 c.c. of Pinachrom, 1 to 1,000, were taken. The plates were immersed for four minutes each consecutively, washed for three minutes and dried. The plates measured 13 by

3c., and the first and second showed maximum sensitive-ness, say, 100, the third fell to 78, the fourth to 70, and the fifth to 60. By dipping for three minutes only, the third plate had a sensitiveness of 90. To obtain even results it is, therefore, desirable not to dip more than two plates of that size in the quantity of solution specified. The bath should then be discarded or receive a further addition of 2c.c. of Pinachrom solution. The bath should be freshly prepared, and not kept for future use. All kinds of plates are not suited for use with this dye. Some are invariably, although otherwise excellent. Great care should be exercised in selecting the light for the dark room, only the rays of the extreme red end of the spectrum being permissible. Even then the plates will be affected very easily, and it is preferable to work in the dark if possible.

* * *

Incandescent Lamp.

The common use of the electric glow lamp is such a comparatively new thing that it is difficult to realise that the first lamp was made by Edison twenty-five years ago. Any form of artificial light has an interest for the photographer, and this form of lamp is doubly interesting from the circumstance that a well-known photographic experimenter and chemist, Mr. Swan, had so much to do in bringing it to perfection. The "Ediswan" lamp is known all over the civilised world, and the story of its birth, in Edison's laboratory, as told in "Cassier's Magazine" for the current month is worthy of attention. The incandescent filament was the great difficulty, and Edison pretty well searched the world for a substance which would, after carbonising, retain its form at a white heat. The first filament tried was cotton thread, which was placed in a little mould in a groove of the shape of a hair-pin, surrounded by charcoal. For five hours this mould was submitted to the heat of a furnace, and at the end of that time the carbon thread was found to be so fragile that it fell to powder as soon as it was removed from its bed. Again and again did this happen with subsequent filaments, until at last a tougher specimen was obtained which, alas, fell to pieces when it was being adjusted to the lamp. Another promising filament was carried away by a gust of kind wind as it was being removed from the laboratory the glass-blowing building. Then Edison and the one assistant who had carried through these experiments determined that they would make a lamp before they slept, or perished in the attempt. They worked on for forty-eight hours, and at last their perseverance was crowned with success. A lamp was made, connected up with the current-bearing wires—and it glowed. Then, and only then, did Edison and his colleague think of rest. They slept for a few hours, and when they woke were rejoiced to see that the lamp on which they had expended so much anxious thought was still aglow. Several days did the little lamp continue burning, and Edison then thought it was time to see how much current it would stand. It bore the ordeal much better than he expected, but at length the breaking point was reached and the lamp went out. Edison soon realised that the invention had reached that stage when it might be brought before public notice, and soon afterwards, the Edison Electric Light Company was formed with a capital of three hundred thousand dollars. The inventor may justly claim that his lamp is now better known, and is far more wonderful than the fabled lamp of Aladdin. In all civilised countries it is being utilised, and it is no exaggeration to say that many millions of lamps are in use continually, for their employment is so widely spread that, in the same sense that the sun never sets upon the wide realm of Britannia, we may say that the carbons never go out on the much wider area covered by these marvellous

little lamps. Their manufacture, together with the work of making fittings, and wiring buildings for their use must give employment to tens of thousands of persons. Aladdin's lamp benefited but one selfish individual, Edison's brings sunshine to thousands.

* * *

Photography for Babies.

The photographic column which appears periodically in several of our newspapers, is one of the signs of the present popularity of the camera, and we welcome it as such. At the same time we feel sorry that we cannot always compliment the writer thereof upon the choice of nourishment which he provides for the sucklings for whom he caters. We take it for granted that these writings are intended for the benefit of photographic infants, for they are generally of the most elementary kind. The gentleman who does the work for one of the leading London dailies travelled the other day a little out of the safe path, we think, when he began his column with directions for "turning" to account bromide paper or P.O.P. which had been already used but not subsequently wanted. Perhaps he did not like to hurt the feelings of his readers by writing "spoilt prints," but that was evidently what he meant. Economy, we all know, is one of the leading virtues, and the art of turning to practical use a waste product has brought fortune to many. It is, therefore, a thing much to be desired that some employment should be found for prints which even in these days of latitude with regard to pictorial excellence will occasionally not come up to the expectations of their producers. What is the method by which such discarded things can once more be made serviceable in the printing frame? The matter lies in a nutshell. All you have to do is to remove the image from the paper, wash it, treat it with fresh chemical solutions, and use it for blue printing. As to the process it is simplicity itself, but let us quote the directions given in case we should not do sufficient justice to them: "The only chemicals necessary are a saturated solution of iodine (the metalloids) in methylated spirit, and a saturated solution of potassium-cyanide in water." Is there any caution suggested with regard to the attributes of this last-mentioned salt? Not a bit of it. Why discourage the aspirant to photographic honours by suggesting difficulties? He is advised to place his prints, while swabbing them with the mixture "on the bottom of a tray," and he will naturally, with the thoughtlessness of youth, employ the tea-tray for the purpose. But, supposing that our friend the photographic babe has the good luck to escape the attentions of the coroner, how much is he likely to gain by this economical use of spoilt prints? His aspirations probably have not soared beyond the quarter-plate size, and he would probably not own to more than a dozen failures if as many. Now a dozen pieces of bromide or P.O.P. can be purchased for sixpence, and we fancy that the iodine, spirit, and cyanide to resuscitate the same number of spoilt prints would cost something more than that, to say nothing of the trouble and the probable undertaker's charges which would follow the operation. But, seriously, the advice given is really of a most mischievous kind. To suggest the introduction into an ordinary household of such a deadly thing as cyanide, even if some important photographic operation could not be done without its aid, would, one might think, be incurring a grave responsibility. But to do so without a word of warning as to its dangerous properties is—well, we do not exactly like to say what we think of it. It is said that everything has its humorous side, and the comic element in this matter is afforded by the advertisements at the end of the column—which emanate from well-known firms who supply bromide paper and P.O.P. How

delighted they will be when they read this fatherly advice to their clients to use up old prints instead of buying fresh paper to work with.

* * *

Popular Taste in Art.

Thanks to photography having come to the help of the printing press, never before were there so many pictures published in periodicals as there are now. It is difficult to recall the time, little more than half a century ago, when Britain had its one illustrated weekly newspaper. Persons who subscribed to that journal, which we are glad to know is still flourishing, would treasure up the numbers, and would have them bound at the end of each volume. Who thinks of doing this to-day? If anyone attempted to bind a quarter of the illustrated journals which he reads, he would have to think about renting a warehouse to hold the accumulative tomes. We have not attempted to make a close calculation of the number of photographs reproduced in half-tone, and given to the world through the agency of periodicals, but we may fairly estimate the output for London alone at some thousands per week. The demand for pictures of this kind seems to be increasing; if it were not so most of the minor illustrated periodicals would cease to exist. So we may presume that the public is satisfied with what it gets, and the proprietors of the journals are content with the result. By the pictures published we are able to gauge the popular taste in art matters, and we are bound to acknowledge, with much regret, that we do not think much of it. Against the old-established leading illustrated papers we have not a word to say. They keep up their reputation for good work, and whether it be a wood cut or a half-tone block we may feel sure that it will not be printed until the best has been made of it under artistic supervision. But the great majority of the new comers into the literary arena seem content to boast of quantity rather than quality, and many of them will put forward as an attraction that each number contains a hundred or more illustrations. We have one of these journals before us as we write, and after carefully looking through its shining pages we may truly say that there is not a single picture in the issue which we should care to look at again. There are photographs of racing eights, football and jumping matches, one or two landscapes, a few portraits of more or less eminent persons, including, of course, an actress or two, some scenes photographed at the theatre, etc., etc. As specimens of photography these are terribly poor, excepting the portraits, which are by well-known professional workers. But most of the other pictures look as if they were done by the rawest of amateurs in the usual happy-go-lucky "snapshot" way. They seem to have been turned into blocks without any kind of retouching, or of that helpful work which a careful editor will have executed on a photograph before it passes into the block-maker's hands. In this way we are flooded week by week with an avalanche of mediocre work which ought never to have seen publicity. And the reason of it all is that the public taste in art matters is at the lowest possible ebb. The educated eye sees and deprecates these things, but the ordinary individual is content if the pictures give him five minutes' amusement, and he does not possess the power of appreciating one above the other for any artistic excellence which it may possess. So the editor and the proprietor can shake hands over the fact that what they serve up to the public is good enough. "'Tis true 'tis pity, and pity 'tis 'tis true."

THE Royal Photographic Society of Great Britain.—Lantern meeting, Tuesday, April 19, at 66, Russell Square, at 8 p.m. Mr. R. R. Beard will give a display of animated photographs.

MISCONCEPTIONS AS TO PHOTOGRAPHIC COPYRIGHT.

II.

SOME three or four weeks back we alluded to certain misconceptions under which some photographers appear to labour with regard to the law of copyright and privileges that they suppose they enjoy under it. One would almost have surmised, as we said then, seeing the length to which the subject of copyright has been dealt with in these pages during the past few years, that every photographer—more especially if he be a professional, for it is he who is most interested, at least pecuniarily in the subject—would be quite familiar with every phase of copyright law. But such seems not to be the case as evidenced by the queries relating to it to which we are constantly replying. Even since the article just referred to we have received others.

Here is one. The correspondent says in effect that he has taken for publication a series of views of local scenery, which he says, from selection of point of view and time of lighting, are superior to any that have been done before of the same subjects, and has registered his copyright in them. He says that now another photographer has taken the same views, planting his camera in precisely the same place as he did, and at about the same time in the day, so that he has got practically identical pictures, which he is now publishing as picture postcards. The correspondent asks if this is not an infringement of his copyright and, if so, what steps he should take. He adds that the pictures, though not actually copied from his photographs, are really facsimiles of them—being taken from exactly the same spots as his were, and with similar lighting. Of course, there is no infringement of copyright in such a case as this. There is a copyright in our correspondent's photographs, but there is none in the subjects themselves, and, as a matter of course, anyone is at liberty to photograph them from any point of sight he likes, whether there may have been other pictures taken of them and made copyright or not.

Here is another point somewhat analogous to the above that we have frequently replied to, and it mostly has reference to lantern slides of pictures in national collections, old engravings, and the like. Some persons seem to think that as the copyright in the majority of the pictures in our national collections and those in foreign ones has long since expired, and also in many old engravings, they are at liberty to copy any of the photographic reproductions of them that have been published either here or abroad. This is quite a mistaken idea. There may not be an existing copyright in the original picture; but a photographer, when he reproduces a copy of it, almost invariably registers the copyright in his reproduction—his work—and so protects that from piracy. Anyone, of course, is still at liberty to copy the original as many times as he may choose, and in as many forms as he likes, and register his copyright in any or all of his reproductions, and one is allowed to copy them, the copyright being in the reproductions.

Some seem to imagine that the photographs of pictures in the foreign galleries, and those in the English ones, that are published abroad, and which command so great a sale here, possess no copyright unless they have been registered here at Stationers' Hall. That is quite a mistake, as it is not at all necessary that they should be so registered. Under the International Copyright Act, if the conditions necessary to secure copyright in any of the countries signatory to the Convention are fulfilled the works become copyright in all of them just the same as if the works were copyrighted in each of the countries. For example, a picture, the copyright in which has been

registered at our Stationers' Hall, becomes copyright in all the countries that entered into the Convention without any forms to be gone through abroad. In Germany, for instance, from whence we get so many art reproductions, no registration of copyright is necessary. The mere publication in Germany secures copyright in the work there and, consequently, in all others, partly to the Convention. Most of the pictures of the late Queen at Windsor, and at Buckingham Palace, as well as those in our national collections, have been reproduced by German firms, but as the reproductions were first published in Germany there was no occasion for the copyright in them to be registered in this country, although the negatives were actually made here.

There is a point that is not so much a question of copyright as of common right which does not seem to be so well understood by many photographers as it should be. It is this: The negatives of his customers are the property of the photographer, but he has no copyright in them; what is vested in the sitter. Although the negative is his property he has no right to use it for any purposes of his own, without the customer's consent. It is illegal for him to sell copies of it, or to use it for specimens or anything of that sort. Sometime back, we remember, a correspondent wrote to the effect that he had taken the portrait of a very pretty young lady, and, after the order was executed, he had an enlargement made and finished at considerable cost to use as a specimen in the shop window. As soon as the picture was shown the father of the lady called and demanded its immediate removal, which was refused. Legal proceedings were threatened, and we were consulted by the photographer, and then he was told that what he had done was illegal, and that he had laid himself open to costly law proceedings. Afterwards, it appears, he offered to sell the picture to the family at a reduced price, but this was indignantly refused, and its destruction at once was demanded or legal proceedings would be taken. When the photographer seemed to think himself an ill-used party because the enlargement had cost him a considerable sum to produce, and was a good specimen, but he could not use it. Why he should have felt aggrieved it is a little difficult to conceive. He had done an illegal thing in using the customer's negative, which he had no legal, or moral, right to do.

Any photographer who has been paid for taking a portrait can, by injunction from the Court of Chancery, be restrained from exhibiting, or selling, copies of it, and will be mulcted, in the costs of the proceedings, as more than one has found to his cost. He may also, possibly, have to pay a certain sum by way of damages. But in the cases we are aware of damages were not claimed. But without damages the costs in a Chancery trial are not readily forgotten by those who have to pay them. This is a matter that many do not seem to be aware of when they exhibit copies, or enlargements, made without the consent of the customers having been previously obtained.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon (the 11th inst.), Sir James Crichton-Browne, Treasurer and Vice-President, in the chair. The Right Hon. the Marquis of Salisbury, Mr. W. B. Anderson, Mr. J. Benson, Mrs. G. E. Broun-Morison, Mrs. Douglas, Mrs. J. Mackenzie Davidson, Mr. J. A. W. Dollar, Mr. Baynton Phipps, Mr. E. W. Linging, Mrs. Master, Mr. J. C. Prince, Mr. A. Short, Mr. H. L. Tidy, Mr. W. Watson-Taylor, and Mr. C. S. Whitehead were elected members. The special thanks of the members are returned to Mr. Francis Gaskell for his donation of £50 to the fund for the Promotion of Experimental Research at Low Temperatures.

RECENT ASTRONOMICAL RESEARCH.

II.

[From "Popular Astronomy,"]

In these photographs the author has also avoided a fault which appears in so many pictures of the Moon which have been greatly enlarged from the original negatives. Sometimes this work of enlargement has been carried so far as to make the granular structure of the film of the original negative stand out harshly even in the finest prints that can be made. Such a glare is unnatural, and is always disappointing to those who rightly expect the soft, continuous finish of a photographic film that will differentiate, in detail, most beautifully and almost perfectly, when it is not over-worked.

The appearance is that these good results could not have been realised without an instrument giving a wide, flat, photographic field, and it is interesting to know how this end was accomplished. From the descriptive part of the photographic atlas it is learned that a twelve-inch objective with a photographic focus of 135 feet and 4 inches was mounted on the side of a hill with inclination of about 30 degrees. The upper end of this long tube came into a second story of a building where the observations were made. At the lower end of it was the objective and a mirror 18 inches in diameter, used as a reflector to throw the light of the Moon through the objective and the long tube to its eye-end. By means of electric motors the mirror and the plate-holder were made to revolve, so as to neutralise the rotation of the Earth on its axis. It is said, by the author, that this novel means of controlling the mirror and the photographic plate, in actual use, worked very well. A good objective of this kind, handled in this way, ought to do fine work.

As an illustration of how the photographs were prepared for the atlas, we will cite one instance which was the first step in constructing the author's map of the Moon. The negative of the full Moon finally chosen was taken, at Jamaica, on the night of August 29, 1901, 16h 50m G. M. T. The image measured 15.7 inches in diameter.

It was enlarged on bromide paper to a diameter of about 27.7 inches. The craters, parallels and meridians were then inserted. When completed the map was reduced by photography to an approximate diameter of 13.7 inches, which is just one ten-millionth of the diameter of the Moon. This would give a scale, measured on the Moon's axis, of about 160 miles to the inch.

It would be profitable to our readers to take up the themes presented by the author in this new book, and give somewhat in detail the new things therein said in connection with each, but this would carry us too far from the object of this already extended notice of this popular work. It will suffice to say that Professor W. H. Pickering has made a most valuable and timely contribution to the literature of the Moon, by the aid of the best modern methods of research. The fact that the book has been written entirely in popular language is one of the best things about it. Intelligent popular readers will find it the best reference book for late knowledge of the Moon in connection with any good text-book on the subject that we know of.

W. W. PAYNE.

INAUGURAL Dinner of Houghton's, Limited.—To celebrate the amalgamation of the firms of George Houghton and Sons, Limited, Joseph Levi and Co., Spratt Bros., Holmes Bros., and A. C. Jackson, under the style of Houghton's, Limited, an inaugural dinner was held at the Trocadero Restaurant on Saturday last, April 9. Mr. G. Houghton occupied the chair, and amongst those present were the heads of the allied houses, members of the various staffs, representatives of the Press, and others, the company numbering about eighty. At the conclusion of the dinner, which was served in Messrs. Lyons' best style, the chairman gave the loyal toast, that of "Houghton's, Limited," being submitted by Mr. Thomas Bedding, F.R.P.S. (Editor of "The British Journal of Photography"). Mr. Edgar Houghton replied. Other toasts were "The Press," "The Works," "The Staff," "The Chairman and Directors," and "The Guests." The enjoyment of a delightful evening was further enhanced by a musical programme, to which the orchestra and several well-known entertainers contributed. The dinner, which we trust signals the commencement of a prosperous career for Houghton's, Limited, was a great success in every way.

SHUTTER TESTING.

In the March number of the "Instrumentenkunde" a paper by Dr. Hans Lehmann, of Munich on the speed measurement of shutters is published. The method made use of is described as follows:—The contact-breaker of an induction coil is removed, and in its place a large tuning fork, which has on the end of one of its prongs a piece of platinum wire, dipping into a small cup of mercury covered with distilled water, is substituted; the secondary terminals of the coil are connected through a Leyden jar to two electrodes fixed on a wheel driven by a small electric motor, and the sparks are photographed by a camera, set up at a convenient distance, with the shutter to be tested. The number of vibrations of the tuning-fork per second must not be too large, or the amplitude will be too small for the make and break of the current to take place satisfactorily. The accuracy of the speed measured is, of course, the period of vibration of the tuning-fork. It is, nevertheless, possible to accurately measure shutter speeds, which are smaller than this period of vibration. This is done by mounting a strip of white paper, or a small incandescent lamp, behind the electrodes, the sparks from which

this tuning-fork the speeds of several shutters were measured, and it was found that the accuracy of the shutters themselves was not sufficient to require the method with increased accuracy of measurement above described. This was especially the case with those to which a friction brake was fitted, but the pneumatic shutters were not constant also, some of the same construction and size varying considerably. Dr. Lehmann then gives some determinations of the speed of various shutters by Bruns (one of the two best German makers), Goltz and Breitmänn, Bausch and Lomb, Steinheil, and Newman and Guardia of London. He speaks very highly indeed of the performance of the last-named shutter, which, he mentions, had been in constant use for two years, and the figures given show that it was the only one of those measured that worked to its indicated speeds. One of the shutters tested was a focal plane shutter, and it was found that variation of the tension of the spring had not much practical effect on the speed. The following table summarises the results, the margin of error being within

$$\pm \frac{1}{145} \text{ sec.}$$

then serve as the divisions of a scale. The period of vibration is determined as follows: A photographic plate is suspended by a fine thread from corner to corner, upon two screws in the camera, in the plane of the image of the sparks. The contact-breaker is set in motion and the thread released by burning it. The image on the plate after development consists of a number of small points, whose distances from the first are proportional to the square of the time of fall respectively. The first point is a small disc, in consequence of the number of sparks having caused a spreading-out of the image before the plate was released. These distances are measured with a micrometer reading to 0.0005 mm. (about 1-50,000 in.). Dr. Lehmann here specially points out that the accuracy of the measurements, in spite of the larger size of the first disc, is not less than that of stellar photographs. The distances between stars of various magnitudes have to be measured thus, and the accuracy is known to be very great indeed. Under certain conditions a series of much weaker points follows each large one; they are due to partial discharges. Dr. Lehmann develops formulæ for calculating the period of vibration, consideration being given to the fact that generally the moment of release of the plate does not coincide with the passage of a spark. For these formulæ the reader is referred to the original paper. The number of vibrations of the tuning-fork used was found to be 148.23 per second. With

A NOTABLE GERMAN ASTROPHYSICIST.

AMONG modern spectroscopic astronomers a high place is occupied by Dr. Scheiner, the distinguished assistant to Dr. Vogel at Potsdam. To him we owe much of our knowledge of various branches of spectroscopic and photographic astronomy—among them the spectra of bright stars, of the important nebulae, and the radial motions of the stars.

Julius Scheiner was born at Cologne on 25th November, 1858. After education in the Royal Gymnasium in his native town he entered the University of Bonn in the spring of 1878 at the age of nineteen. While still a student he became interested in astronomy, and Professor Schönfeld appointed him assistant in the Bonn Observatory.

After six years' service at the Bonn Observatory Dr. Scheiner was called to Potsdam Astrophysical Observatory as assistant in 1887. In the same year he assisted Dr. Vogel in his work on the radial motions of stars. The radial motion of each star was measured independently on the plates by both Dr. Vogel and Dr. Scheiner, and the mean of their results was used to denote the motion of the stars in the line of sight. Dr. Scheiner's name is connected with all Dr. Vogel's important spectrographic investigations.

Dr. Scheiner's photographs of the spectra of bright stars, taken at Potsdam, are worthy of special mention.

In 1890 Dr. Scheiner published his well-known volume, "*Die Spectralanalyse der Gestirne*," which was in 1893 translated, revised, and enlarged by Professor Frost, then of Dartmouth, New Hampshire, now of the Yerkes Observatory. In the preface to his work Dr. Scheiner remarked: "Hitherto no text-book has existed for this chief field of spectrum analysis—astronomical spectroscopy."

This want was filled by Dr. Scheiner's magnificent piece of work, and his book is now an authority on spectroscopy. The volume is divided into four parts—spectroscopic apparatus, spectroscopic theories, the results of spectroscopic observations, and spectroscopic tables. In the third part of the volume Dr. Scheiner gives an admirable summary of the work of the leading modern spectroscopists. In addition to "*Astronomical Spectroscopy*," Dr. Scheiner is author of several other volumes on astronomy. These works are "*Die Photographie der Gestirne*" (Leipzig, 1897), "*Strahlung und Temperatur der Sonne*" (1899), and "*Der Bau des Weltalls*" (1901).

On 9th September, 1891, Dr. Scheiner obtained, with the 13-inch photographic refractor of the Astrophysical Observatory at Potsdam, a plate of the great star cluster in Hercules known as Messier 13. This was the first plate on which the component stars were sufficiently well defined for the purposes of exact measurement. Accordingly, Dr. Scheiner prepared a catalogue of 853 stars in the cluster, the positions of which he checked with great accuracy.

In 1893 Dr. Scheiner published a drawing of the Xi Persei nebula, discovered by Professor Barnard in 1885. Dr. Scheiner's drawing was the result of five photographs obtained with a small instrument of four inches aperture. He found that the Xi Persei nebula was not much smaller than that in Orion, and that its borders are more brilliant than its centre, which is comparatively obscure.

In 1894 Dr. Scheiner succeeded Professor Spörer as "Chief Observer" in the Potsdam Astrophysical Observatory, under the direction of Professor Vogel. In the following year he became Professor of Astrophysics in the University of Berlin.

In 1898 Dr. Scheiner photographically determined the positions of seventy of the stars in the Orion nebula, which cannot be proved useful in a discussion of proper motion. He compared the positions of stars as deduced from his photographic researches with earlier measurements by Gould. From the fact that the positions as measured by Dr. Gould and Dr. Scheiner at an interval of twenty years were practically the same, it was deduced that the stars remained practically stationary—in comparison, that is, with the stars of the tapezium—and are not physically connected with either the tapezium or the great nebula. In the "*Astronomische Nachrichten*," Dr. Scheiner has described his researches as to the nature of nebulae. He considers that they are composed of rarefied matter, their temperature being exceedingly low.

In January, 1899, Dr. Scheiner obtained a magnificent photograph of the spectrum of the Andromeda nebula, with an exposure of seven hours. Dark rays were seen, which interrupted the continuous spectrum, and Dr. Scheiner inferred them to correspond to the Fraunhofer lines in the solar spectrum. This points to the conclusion that the Andromeda nebula is actually a cluster of stars of the second type, too distant for the individual stars to be visible.

Dr. Scheiner, assisted by Dr. Wilsing, of the Observatory at Potsdam, has investigated the motions of nebulae in the line of sight by means of Doppler's principle. He has also made many investigations on both stars and nebulae and on the canals of Mars. He photographed the zone of the heavens for the International Chart of the Heavens undertaken by the Observatory at Potsdam. In all, he has published forty-four papers.

THE PHOTOGRAPHY OF GOLF.

[The following review of Mr. G. W. Beldam's book on "Great Golfers: Their Methods at a Glance," appears in the first number of "C. B. Fry's Magazine."]

MANY books have been written on golf—some of them might, perhaps, judiciously have been left unwritten. But of all the volumes ever penned concerning the game, the one before us is undoubtedly the most original. "Great Golfers" is not only the book of the month, but the best book on golf instruction yet produced. Indeed, it has two entirely novel features—the device which shows the stance, and action-photographs, or photographs taken while the player is actually making the stroke.

No book hitherto has been able to show the exact stance of the player for any stroke. Yet so simple is the idea of marking 6 in. squares on the ground that one wonders it has not been done before. For instructional purposes the advantage is very great, for stance is of as much importance in golf as the position of the feet at cricket when the actual stroke is being made. Hitherto, as the author points out, photographs have been of little use for teaching the positions of the feet, which vary according to the stroke played. In this book we are left in no doubt about it at all; moreover, each reader can experience the effect on his play by standing for any stroke shown in the book exactly as Vardon, Taylor, Braid, or others do. It strikes us, by the way, as an excellent idea that the author has arranged for a golf stance mat to be placed on the market, which will be of linoleum, and have the 6 in. squares marked on it to correspond with those shown in the photographs. Who has not noticed beginners and others asking the professional to let them stand in his foot-prints for this very purpose?

Then, again, the point of view of the camera always being the same—viz., looking directly up and down the middle line at right angles to the intended line of flight of the ball, there is ample scope for comparing the methods of all the players. If a player is standing for a low ball, or a sliced ball, the position of the shaft, relative to this line, shows the difference at once. And we are not left in doubt as to the exact line of the intended flight of the ball, which is along the line on which the ball is placed. As Mr. Beldam points out, the stance is therefore the more readily understood. It is the outcome of a simple idea, but one which accomplishes much.

As regards the other feature of the book, action-photographs, Mr. Beldam is, we believe, the first to make a new departure in the illustration of golf books, and to attempt to "time" the golfer at the top of the swing, standing quite close to the subject. He must evidently have aimed at catching that point in the golfer's swing where the club is imperceptibly (in most cases) checked, and commences to return on the downward swing, for most of the photographs are so sharp as to create doubts whether the golfer could have been playing the stroke. The movement of the garments, however, and the action in the photograph prove that the stroke was actually being made.

To accomplish this, perfect timing with the shutter of the camera must have been imperative. We have ventured to ask Mr. Beldam "how he did it," if he had many failures, or took many pictures of the same person for the same stroke. Here is what he said:—

"It is all a question of eye and hand, as in any other game, but two things besides are most necessary—a camera with a full-sized viewfinder and a focal plane shutter, and, a knowledge of the golfing swing; in other words, the camera artist must be a golfer. The fact that when the button is pressed the full-sized reflector springs up and releases the focal plane shutter really helps the operator to time more perfectly. There is only a fractional part of a second between the pressing of the button and the releasing of the shutter; the reflector has to spring up to get out of the way, and release the shutter. Hence I soon found I had to allow for this, and "press the button" just before I wanted to. This short space of time, in my opinion, just fits in with the golfing swing, and also compensates for the difference there would be between the eye seeing and the hand pressing. I therefore watched the wrists working, and not the club head, and I soon found that practice gave me the necessary knowledge when to press. I seemed to know if one had been mistimed, and immediately took another of the same stroke.

"My failures on this account were not many; out of nearly three hundred photographs taken, a dozen failures from mistiming is not a great number. Unfortunately, whilst at the Amateur Champion-

ship, owing to a defective changing box, I lost about eighteen valuable snap-shots.

"When taking a great number in one day I seemed to get set, as one does at cricket, and could then be certain of my efforts being absolutely timed. The top of the swing, of course, requires more timing than the finish, but the most ticklish thing is to catch the ball at, or immediately after, impact in the drive, so as to show the ball and driver on the plate. Of course, in such a case, there is considerable movement of the club and the ball, but this gives a better idea of the pace at which they were travelling, especially when it is remembered at what speed the shutter was working, viz., at 1-1000th to 1-1250th of a second."

From the foregoing it will be seen that golf-action photography, to get the best results, requires almost as much timing as golf or cricket. Enough has been said to demonstrate that the second feature in the book is a new departure, and we can truthfully assert that the photographs do all Mr. Beldam claims for them. It needs only a casual glance to show the individuality of the players coming out in every photograph. How different, indeed, from the posed and wooden illustrations one often sees displayed in golf books! Action-photography is a word which seems to have been coined by Mr. Beldam as a safeguard against misinterpretation! We think he need have no fear on that score. The name is a good one, and full of meaning.

These two ideas, the stance device and the action-photographs, stand out as the two prominent features of the book, which is bound to mark a new era in practical golf instruction, whether to the beginner or scratch player. But it must not be thought that these are the only features. It is a book full of infinite variety, and the arrangement has been evidently well thought out.

Wisely keeping to his subject, instruction by means of photographs, Mr. Beldam leaves others to deal with the history and technical developments of the game. His own chapter on "Instantaneous Photography in Golf" should capture the interest of the golfer who knows anything at all about photography. And his chapter on "Cricket and Golf" is written with the keen insight of one who is not only a theorist, but can verify his theories by putting them into practice. As one of the leading men in the Middlesex eleven, Mr. Beldam's name needs no introduction. As a golfer, if he would only give up that "wretched game of cricket," he would assuredly come rapidly to the fore.

That Mr. Beldam has a keen, observant eye, and a mind for details, is shown by his chapter, which is the keynote to his book—"Instruction by Illustration." Throughout the book he tries, whether talking of golf or cricket, to inculcate principles into the mind of the reader; and a noticeable quality is the absence of all dogmatism. Though he has got hold of principles, he sees that individuality must come out in interpreting them. Hence he says that golf (and cricket) can be played well in many different ways. The principles do not vary, but individuality does; it is the beauty of such games as golf and cricket that they leave plenty of scope for personality.

After these three chapters come four by the famous quartette of professionals—Vardon, Taylor, Braid, and Herd—each of whom writes notes on his own methods of play. In Vardon's portion, what seem to be entirely new ideas are given birth, and he analyses the golfing swing in a masterly yet simple way. Vardon makes golf look a very easy game, and it would appear that he has let readers of this book into his secret, for his notes on the swing, and the manner in which he plays the push stroke, how and when the knees should work, are an explanation as lucid as one could wish.

People who think that Vardon simply walks up to the ball and strikes it in the way he does from sheer natural ability, and after the manner of the parrot, will here see that this great player has method in the "mad" way he plays golf! His game looks simple, his deductions are simple, and the result is simple! For Vardon is acknowledged by even those who most closely challenge his supremacy to be the best golfer who ever lived. We shall be very much surprised if the manner in which he has "given away" his game and methods does not help very many golfers vastly to improve their game.

Taylor's notes are full of clear-headed ideas. If you see him play, he gives you the impression that he is determined and means to accomplish what is in his mind. His notes are written with like precision. His methods vary from Vardon's, for his full swing never

exceeds the horizontal position. For this reason he starts bending the knee sooner than Vardon in the upward swing of the drive. Indeed, Taylor's drive would seem to be but a half shot and wrist work, plenty of it! Yet he has been known to outdrive even Braid on his day, and his straightness is proverbial. His remarks on the "Mashie," on which club he is easily the greatest authority, are very explicit and well thought out. They should greatly help those who wish to excel in this most fascinating yet difficult part of the game.

Braid's annotations, too, are decidedly characteristic of the man. There is no waste of words—short, pithy sentences, full of instruction, give the man and his methods. Yet it is quite clear that he, like Vardon and Taylor, has his reasons for every stroke that he plays. As perhaps the longest driver in the world, his notes on the drive should prove most useful. His method of knee action in the drive seems rather to coincide with Vardon's.

Lastly comes Herd, a player of the brilliant order. His remarks are particularly interesting, as his methods differ somewhat from those of the other three. There is more right-hand grip with him, and consequent tighter grip of the left. He knows, however, how to let the right hand in at the right moment, and in the right way. Here we have an example that golf can be played successfully in different ways. He also lets his body into the stroke more than the other three, as the photographs clearly show. His notes on spoon play are a valuable addition to the book—coming as they do from a famous exponent of that club. Like Vardon, Taylor, and Braid, he has evidently given the game a good deal of thought, and worked out for himself his own individual style.

We rather fancy these four chapters will open the eyes of those who do not give the professional credit for thinking powers in regard to his game, but rather consider it as merely the natural outcome of much play, and fancy that he never went through the trying times which the goddess of golf requires of her votaries. Possibly, the reason why we have never been given such a wealth of advice from professionals before may be that they have not had photographs in which they could see their own methods portrayed. Mr. Beldam, we say again, is to be congratulated on getting together, in conjunction with his pictures, such a welcome addition to golf literature, and he has been wise in letting each professional state his own case.

Then we find the book again varied. No longer each player tells his own story, but the services of that most capable writer and brilliant exponent, Mr. Hilton, have been requisitioned. Like that of the author, his is a mind for detail, and he possesses a keen power of observation. Necessary qualities are these for the task he has been allotted, that of criticising the play of the various amateurs in the book; and being the only amateur who has twice won the open championship, and beaten all comers, Mr. Beldam has been well advised in securing his services. The notes on his own play are most interesting, and full of valuable hints. He is most candid about the rubber ball, and it would seem to bear out what we saw stated not long ago, that the reason for his slight falling off lately was perhaps his failure to master the eccentricities of the rubber-covered ball. He says himself that in approach shots it requires a different treatment to the gutty, and a different stroke to the one he has been accustomed to play. But it cannot be long before a golfer of his calibre acquires the necessary skill to treat the new invader successfully!

In criticising the games of the other amateurs, Mr. Hilton, has performed a difficult task with tact and ability. He has, we imagine, been helped in his task, however, by having action-photographs before him, and he brings out most ably the value of photographs taken in this way. For instance, in Mr. Hutchinson's case he shows how he moves the fingers of his hand in making the drive, and how at the finish they are fighting which shall hold the club. The photographs clearly prove his points. On the whole, Mr. Hilton's remarks are most pleasant reading, and from time to time he throws out valuable hints to beginners and others. He seems to understand well the difficulties of amateurs, and his advice should command every respect. In treating the series of Miss Adair, who (the author says through want of space) is the only lady champion in the book, Mr. Hilton seems to bewail the fact that skirts interfere with his task of criticism! As he humorously puts it, after doing his best to analyse her characteristics, "the dictates of hereditary fashion do

not allow a sufficiently close diagnosis to be made of her methods!" and "it is mere deduction."

The photographs of Miss Adair, however, only make us wish some other ladies had been included in the book. We will hope that it may be supplemented with another volume at some future date. Possibly "great golfers" in America may then be included, notwithstanding the talk of the so-called decay of golf there—a sure sign that it is taking deeper root. Mr. Hilton's pages make pleasantly light reading; he has fulfilled his task well. His last chapters, on "Putting" and "Theory and Essentials," are excellent, but it is doubtful if all will agree with him that putting is a separate part of the game! Yet, for the purpose of comparison, this chapter is no doubt better kept itself, as it introduces again a nice variety in the arrangement. We may safely say, in conclusion, that this book will take a great hold of the golfing world. Every golfer must have one if he is to keep pace with the times. For beginners, as well as for scratch players, it is easily the most helpful we know, for it does not make the mistake of treating beginners as beginners, but is rather written for the average player. Where all will find it so useful and helpful is in the fact that on every page golf is seen as it is played by our best exponents, and the reader is left to choose for himself. It will so appeal to those who like to compare the different styles and methods of the best golfers. Altogether it is a most fascinating and delightful work. The collection of photographs alone, two hundred and sixty odd, are of splendid value for the price charged for the book. They are a unique collection, and will hand down to posterity the methods of the finest golfers of our times.

A USEFUL PRINT METER

LIKE many amateur photographers, it is, and has been, a craze to come possessed of most new things, which from time to time inventors and dealers combine to place temptingly before us; and looking through one of my drawers just now, three or four of these useful little pieces of apparatus intended to do away with waste prints (when we indulge in platinotype or carbon) were come across, and the number of shillings they represented came somewhat of a shock, when one thought how little use they really were put in practical work.

As in most other matters connected with the practice of photography, it always seems as if the last new—I was almost saying toy, the latest acquired implement will, perhaps, sound less frivolous, the only one of any real assistance. One matter in which print meters have proved in a slight manner defective, is from exactly the same difficulty experienced when using meters designed to help one to estimate the needed exposure to be given a dry plate or film, namely, in telling with anything approaching certainty the exact point when sufficient darkening of the strip of sensitised paper has been reached, due, mainly, in this case, to the strip of bromide paper employed being very sensitive to the influence of moisture retained in the atmosphere, and when so affected printing a pinky colour, which to many, at least, proved a stumbling block in the way of rightly estimating the depth or darkening which has been reached; so, also, with print meters, it being not always possible to obtain a print-out silver paper which, when acted upon by light, gives anything like the same tint or colour as the standard one used to the little instrument.

Of course, we are all aware the mere colour of the printed test has no part in this matter, all that is needed being to darken it to a certain depth, irrespective of colour matching entirely; but simple as this seems, it has undoubtedly proved an obstacle to many, and especially, of late times, those so-called actinometers or meters where strips of bromide paper are used to gauge the action of light have been sent out with the covering piece of glass either, in one case, a yellow colour, or in another well-known and widely-used meter is covered by a small blue glass, either of which largely does away with any uncertainty in judging how the darkening is proceeding, any slight variation of colour in the sensitive paper, from whatever cause it arises, is obviated in quite a remarkable manner.

Under such conditions, it really becomes difficult to go far astray in forming a decision as to when the right moment has arrived, and the test is completed.

Just as it has been with that particular form of light gauge, so

also has it been, in less extent, perhaps, when using a print meter, for reasons already indicated.

Now, my last acquired fad in this direction, for use when printing with papers where it is advisable to rely upon some such guide, is a small, neat affair, which tells me as it lies on the printing board, or frame, just exactly how matters are progressing at a glance, without need to touch either meter or print.

It seems quite indifferent as to what make of P.O.P. is used, or what particular colour the deposit assumes, either bright red or purple, for whichever it be, when once it has been placed behind the graduated slip through which printing has to take place, the result is the same, just a plain, simple, easily read record of what is going on. So that once having obtained the right number of tint to print to for any particular negative, when employing any particular kind of process of print making, and using a test slip of one degree of sensitiveness, printing, especially of large pictures, loses its terrors, and failures from over or under printing become things of the past—or should, which is slightly different sometimes.

In appearance it is a narrow metal frame from three to four inches in length, slightly under one inch in breadth, and a quarter of an inch in depth. It opens in book form, one side the two leaves being held by a strong spring, on the other side there being a sliding indicator, which is pushed to any particular number of tint, down the centre being openings through which the printings take place. One-half down the entire series (there being ten such openings) is placed the standard tint, underneath which is a narrow pad of felt to press the sensitive strip of paper into contact, and hold it there.

So far there is nothing which differs in essentials from the rest of print meters, except one or two small particulars. But from this point it differs from any which have come under my personal notice, in that the cover glass is of an evenly graduated yellow colour, the result being, as already pointed out, there is no necessity, when once the strip of P.O.P. has been placed in position and the instrument closed, to do more than glance at it from time to time to see exactly how printing is progressing, in itself no small saving of time and trouble, especially when light is of high actinic quality, and to examine by opening a meter means taking it indoors, or a shady corner, before uncovering the enclosed slip of sensitive material.

After having put this small print guide to some amount of practical use the last few months, it seems quite as good, and indeed in many respects far in advance of others more commonly met with in dealers' shops; and that is all, except to repeat, it is a good and helpful bit of apparatus, and costs but three or four shillings.

To any desirous of using the same principle, there should be no difficulty in making a print meter with very much the same action, using yellow glass in place of opal or the clear glass screen of ordinary print meters every one is so familiar with.

W. THOMAS, F.R.P.S.

FORTHCOMING EXHIBITIONS.

April 20-26.—Swansea Photographic Club. Hon. Secretary, W. R. Stephens, 14 and 15, Temple Street, Swansea.

May 2-4.—Bristol Eidestdffd. Photographic Section. Hon. Secretary, Arthur B. Cleaves, Westbury-on-Trym, Bristol.

May 11-18.—Plymouth Photographic Society. Hon. Secretary, Wilfred Grist, 105, Old Town Street, Plymouth.

May 16-28.—Photographic Society of Ireland. Hon. Secretary, E. Webb-Smith, care of Royal Dublin Society, Kildare Street, Dublin.

May 24-28.—Devonport Camera Club. Hon. Secretary, A. J. Catford, 78, Charlotte Street, Devonport.

June-October.—Glasgow Photographic Exhibition. Secretary, Art Gallery and Museum, Kelvingrove, Glasgow.

WE have received a leaflet from J. Lizars, of Buchanan Street, Glasgow, containing a list of "Challenge" cameras for sale at reductions ranging from 33½ per cent. to 50 per cent. off list prices.

WE have received specimens of Messrs. Elliott and Sons' latest show-cards advertising the Barnet specialities. They are high-class productions, and would enhance the appearance of any photographic dealer's shop.

THE REPRESSION OF THE BRITISH INVENTOR.

[In justice to Mr. Friese-Greene, whose letter appears in our columns this week, we print his letter to the "Journal" of the Society of Arts of March 25, 1904.—Eps., B.J.P.]

As a British inventor with more than twenty years' practical experience of the British patent laws, and having taken out some thirty patents, I have been extremely interested in the correspondence in your "Journal" on the above matter, and I heartily agree with the position taken by Mr. Lowry and Mr. Boulton, that the present system prevailing in the British Patent Office is iniquitous and unjust to the inventor, and has done more than almost any other one thing to discourage English ingenuity and enterprise.

It is not my purpose to defend the German or United States patent laws, which may be (and doubtless are) open to the criticisms made by Mr. Abel. The fact that these countries have made mistakes in this line in no wise minimises the mistakes which our country has doubtless made, and I therefore do not propose to enter into a discussion of Mr. Abel's letter. What interests me as a British inventor, are the facilities the British Patent Office affords me for protecting and exploiting my inventions. My experience is, that it would be hard to devise a method which is more unjust to the inventor than the one which has prevailed in England for the last twenty-five years at the least.

The Act of 1902 has improved matters somewhat, but it does not get to the root of things, as it retains the very burdensome and unjust renewal fees which, coming as they usually do in the case of a new invention, just at the time when the inventor is least able to meet them, cannot be met, and therefore the inventor loses his time and the moneys already paid.

As Mr. Boulton very justly states in summing up his admirable letter: "Can anyone maintain that it is just that the patentee pays for his protection 1,188 times as much per annum as the author?" This is what the present patent law provides. To give you a practical illustration in my own case, which is one of many (and I may say that I have made so many valuable inventions that I am now financially ruined, although many of my inventions are practical and commercial, and have made thousands and hundreds of thousands of pounds for others), I will instance one case—i.e., the cinematograph.

I will not enter into the history of this invention, except to say that I began working on it over twenty years ago, long before it could be possibly made commercial, for the reason that, at the time I began my experiments and for several years thereafter, celluloid was not made in long lengths, and, therefore, could not be used for cinematograph films.

I first showed my invention at a meeting of the Photographic Society, Pall Mall, in 1885. The invention itself was first patented in 1889. This patent gives a complete description of the cinematograph camera which is used to-day, but it was not then commercial, for the reason that celluloid film was difficult to secure, was expensive, and was too opaque to give proper results upon a screen. In fact it was not until 1893 or 1894 that a non-shrinkable celluloid photographic film transparent enough to enable pictures to be projected upon a screen was produced commercially.

I took out a further patent in 1893. This patent covered the projecting apparatus, and is the first machine of its kind. In 1896 I took out a further patent, covering certain improvements and attachments for this machine; and this patent, together with my patents of 1889 and 1893, are the master patents on this invention. I had expended thousands of pounds and ten years' time in perfecting this invention.

Directly my patents were published others profited by my work, and brought out various forms of machines, all of which I maintain are infringements of my patents; but I was not in a position financially, owing to the large amount of money I had expended on this and other inventions, to properly protect my rights in the Courts, which would have cost me, as I was informed, from £2,000 to £5,000 at least.

The fact that I had obtained British patents on my invention did not in any way practically protect my rights as against infringers, who, knowing the practices prevailing in the Patent Office and in the Courts in reference to inventions, took the chances of a patent action, and exploited infringements of my invention for their own profit without payment of a penny to myself.

That is the condition to-day, with the exception of two firms in the trade who, as a matter of fairness to me (although I have not yet been in a position to bring action to protect my rights) have entered into royalty arrangements, and are paying me royalties on my invention, although nothing like as large royalties as I should have been entitled to receive, and which they no doubt would have been prepared to pay, had the patent laws been so framed as to discourage infringers, rather than encourage them, as is the case to-day.

I do not say this as any reflection upon the two firms who are paying me royalties. Quite the contrary. They could afford to pay me much larger royalties had the English patent laws been so framed as to enable me to protect them from unlawful competition. As a matter of fact, these firms are to-day paying royalty, which the other firms are not, and are, to this extent, hampered in their business by reason of their recognition of my rights. In other words, the practical result is, that the infringer is protected by the present laws, whereas the inventor is in the position of paying the British Government for the privilege of giving the details of his invention to the very men who are encouraged to infringe it.

This has been my experience with my cinematograph invention, and also my experience with many other of my inventions, but space prevents my going further into details.

Now as to practical suggestions, I do not for a moment imagine that the framers of the patent laws have deliberately tried to draw them so as to favour the infringers and hamper the inventors. On the contrary, I assume that it is the desire of the Government to frame laws which will encourage and protect the honest inventor.

Without going into detail, my suggestions are briefly as follows:

1. That a thorough search be made by the British Patent Office before the patent is granted.
2. That the cost of this search should be included in the initial fee.
3. That when a patent is once issued by the English Patent Office the presumption is not that it is bad, but that it is good, and that this presumption be one that the British Courts are instructed to recognise in any action for infringement.
4. That the penalty for infringement (where the infringement is clearly proved) be not merely an injunction against further infringement and the actual damages proved (which latter are almost impossible of proof in many cases), but should be substantial and exemplary damages which shall be sufficiently large to discourage others from attempting to infringe what they know to be a valid British patent. In other words, "make the punishment fit the crime," which is not the case under the present law. In fact, not infrequently happens that an inventor may win his action for infringement and be ruined by the delay and expenses he has incurred over and above his damages and taxed costs.
5. Any man stating in his application that he is the original inventor, when it is proved he knows he is not, should be held to be guilty of perjury and should be prosecuted by the Public Prosecutor at the public expense.
6. Make one fee cover the entire cost of the invention for the full term. You can figure out for yourself what it means to maintain twenty-five or thirty British patents, many of which while they are the basis of very valuable inventions, may be premature, in that certain features of the invention are not yet perfected, or the trade not yet sufficiently advanced to appreciate its value.
7. The appointment of a Royal Commission consisting of practical men who shall take evidence on this whole subject and report their recommendations to Parliament. I would respectfully suggest that you call before said Commission some of the practical inventors and mechanics who have been either discouraged from patenting their invention, or if they have been foolish enough to patent it, have been ruined by the expensive processes which are necessary in order to protect their rights. I think this Commission would get some good, solid facts which would be of the greatest value in formulating a law which will do substantial justice to the English inventor and encourage the industries of the country.

In other words, I make a plea for justice and common sense in our patent laws. Make it not only possible for a rich inventor to protect himself, but encourage a poor inventor to patent his idea with a certainty that he will obtain a proper return for any good invention he may make, and full protection of his rights without danger of being financially ruined by his own inventive genius at his attempt to contribute something to the welfare of his country.

W. FRIESE-GREENE.

THE SEPARATION OF DEVELOPMENT INTO PRIMARY AND SECONDARY ACTIONS. CONSEQUENT EFFECT UPON THE CORRECT RENDERING OF LIGHT VALUES AND THEORY OF THE LATENT IMAGE.

[A paper read before the Royal Photographic Society.]

DEVELOPMENT of the latent image has always more or less appeared consist of two distinct actions—the reduction of the haloid compound which has been acted upon by light and a further strengthening or intensification, either as in the collodion process as an addition of silver from without, or as in the gelatine film from within the film itself.

In the case of collodion this action is evident, but it is not so readily seen in the development of the gelatine film; still, there are indications that such is the case. For instance, if a series of exposures be made as for the estimation of the speed of the plate, it will be found that if one portion of the plate be developed very quickly and the other very slowly, a great difference in the results will be obtained. In the case of the slow development there will be found at first a marked increase both in the speed and latitude of the plate, but as the development is increased both will decrease and finally become approximately the same as the quickly-developed portion. Again, the same amount of detail in the under-exposed portion of a negative is found when development with different developers is carried on till the action ceases, whilst at the same time there is often a great difference in the density of the correctly-exposed portions. Also very slow plates often show the weak detail much colder in colour than the stronger portions.

That the image is not necessarily solely formed from the silver haloids which have been acted upon by light has been shown practically by Sir William Abney, who succeeded in obtaining an image on a film added to the plate after the exposure had been made. (*Treatise on Photography*, 1878, p. 99.)

The present paper may be taken to be a continuation of one on "Standard Plates and Some Causes of Apparent Alteration in Rapidity" (*"Photographic Journal,"* January, 1895, p. 118), followed by "The Two Latent Images (Organic and Inorganic): Development before and After Fixing" (*"Photographic Journal,"* 1898, p. 264), and in both of which, as again now, it has been assumed as a working hypothesis that the action of light upon the sensitive film is definite, and should any well-established law appear to be broken, this must necessarily eventually be found to be due to secondary causes. It has also been assumed throughout that at first the action of light is purely molecular, the later liberation of the halogen counteracting development.

In the *"Photographic Journal"* for August last will be found a communication from Mons. Léon Vidal "On the Utilisation of Old Sensitised Plates which have been Fogged," the discussion upon which showed that there was a great difference of opinion upon the action of potassium bichromate upon the development of the latent image, and this difference could not be said to have been factually solved by the suggestion that the results obtained by Mons. Vidal were due to the dilute solutions used.

As expected from experiments made at various times, it was found upon repeating his experiments that the statement that the latent image was not destroyed, but only its development delayed, was fully proved, a 10 per cent. solution used for five hours not showing any destruction of the most minute detail.

If not carefully washed between the bichromate bath and the development, it is true one would for practical purposes consider that the image had been destroyed, but most comes back again, as stated, with the washing, though not exactly as before, and in some cases the colour of the deposit is found to be materially changed.

We must now take the opposite extreme, and consider what is the effect of developing the plates with some of the bichromate purposely left in the film, as this has led to the results to be described commencing with a slow plate, slide 1 shows plates which have had equal exposures in the Chapman Jones Sensitometer, A showing normal development, B the same development after treatment with weak potassium bichromate, but without the thorough washing given by Mons. Vidal. The scale of gradation is totally different, square 1 in A being about equal in density to square 1 in B, and none of the halation of A is shown in the other. The whole gradation of B has been entirely altered, taking double the number of squares to

reach density of 8 in the other. If we explain this by saying that the time of development of B treated with the bichromate has been too short, we are met with this fact that squares 15 are alike in both. We will, therefore, follow this further with comparative trials, tabulating measured densities. To facilitate experiments, standard negatives have been used, made up with layers of fogged cristoid films. This method was adopted so that all exposures should have the same duration, the intensity being varied only. The importance of this was fully dealt with, *"Photographic Journal,"* 1895, pp. 124-127. The exposures have been calculated from the measured densities, and are approximate only, as an average printing factor of .8 has been taken for all plates as suggested by Messrs. Hurter and Driffield (*"Relation Between Photographic Negatives and Their Positives,"* *"Journ. Soc. Chem. Ind.,"* February 28, 1891). Any error only affects the development factor obtained equally in each case, and with which we are not at present concerned. Six, or even more, strips could be cut from the same plate after the one exposure had been made, comparative results being thus obtained readily.

A plate, slide 2, was given an exposure under the negative, and separate portions thus treated:—

- A. Normal developer, 1 minute.
- B. 1 per cent. potassium bichromate, 1 minute, washed quickly, development 3 minutes.
- C. 5 per cent. potassium bichromate, 2 minutes, washed quickly, development 3 minutes.

Diagram 1.

The first point to notice is the approximately equal density of the shortest exposure in all three cases (the development having been timed to secure this result), and the wide divergence of the last.

The development of C has been delayed much more than B by reason of the stronger bichromate and longer time of immersion.

This effect will be better considered by plotting the curves (Diagram 1), when we find that the first effect of a weak solution of bichromate in the film is not to destroy the exposure, but to push back the correct and even over-exposed portions into one long under-exposure. (A, normal, compared with B and C treated with bichromate).

Comparing curves B and C, it will be seen that whilst in B there is practically no straight or correct portion, in C, owing to the more severe treatment, the earlier exposures are coming again into a straight line, thus indicating that with still further treatment a still better result could be obtained.

Before considering the effect of stronger solutions of bichromate or other agents such as chromic acid, permanganate of potash, etc., which give similar results, it will be as well to trace the action already obtained further into the over-exposure period, and thus

clearly show that we are dealing with other influences within the films beyond the simple action of light.

Diagram 2, Curve D.—Normal Development, 1 minute.

Diagram 2, Curve E.—1 per cent. potassium bichromate, 1 minute; development, 1 minute.

Diagram 2, Curve F.—1 per cent. potassium bichromate, 1 minute; development, 2 minutes.

Diagram 2.

In both curves E and F, the under-exposed portion is followed by a correct period obtained entirely from the normally over-exposed portion of the plate. A new correct period has been obtained having a far greater latitude than that given by normal development.

Thus far, we have only obtained a similar result to that shown ("Photographic Journal," 1898, p. 273), when weak bromine was used between exposure and development and a long correct period of 1 to 4,000 was obtained. Now that similar effects are shown by the use of other agents, it seems probable that the bromine was acting in the same way, and not, as was then supposed, in rehalogenisation. What the precise action is does not as yet appear certain; oxidising agents and hydrochloric acid to some extent act well, and there seems to be something required beyond the mere neutralisation of the developer within the film, for apparently it is necessary to destroy or modify the developing agent, because success is more readily secured when the proportion of developing agent is kept low and the alkali high.

If what has so far been shown were all that could be done, it would only amount to a much simpler way of securing the correct rendering of very great contrasts than that previously given, but by continuing the action either with potass. bichromate for a long time, or using more powerful agents, such as chromic acid or permanganate of potash, fresh results are obtained altogether different.

Diagram 3 shows three curves:—

G.—Normal developer, 1 minute.

H.—10 per cent. bichromate of potassium, 10 minutes; development, 3 minutes.

I.—10 per cent. bichromate of potassium, 5 hours; development, 3 minutes.

With all plates, fast or slow, however completely the general reduction of silver may be checked or driven back, there is always something left which can gradually be brought out with prolonged development. As the action of the bichromate, chromic acid, etc., increases, the curve becomes gradually flatter, and thus curve I finally shows a new and practically correct period extending through all the exposures, and totally distinct from the normal, G, and the short application of bichromate, H.

This new curve usually has a period of under exposure commencing at the point of the first visible reduction by prolonged ordinary development, following by a long straight line of correct exposures extending to or even beyond the point where reversal is shown with ordinary development.*

* With any given plate the best strength and time of treatment with, say, 10 to 1 per cent. chromic acid must be found by trial. Potassium permanganate works well, but a bath of potassium metabisulphite is required to remove the oxide.

The curve thus found is so evidently related to the light received by the plate that, were it not for the curve of under-exposure, it would be all that is required correctly to represent the complete action of light. This will therefore be called primary development, and that which has been kept back secondary, whilst the two combined are shown by the Hurter and Driffield characteristic curve of the plate.

Diagram 3.

Diagram 4.

The desired action, however, requires that the straight line should commence at the point of first appearance of silver reduction, and continue until signs of exhaustion of the silver in the film become manifest, and to obtain the nearest possible approach to the ideal curve practically, the slowest plate to be found is the most likely to give the desired result.

Diagram 4 is obtained from an exceedingly slow lantern plate. Two exposures were made under the negative, the one being sixteen times as great as the other. Portions of each were developed at the same time. It will be noticed that curves K and L, developed in the ordinary way, do not coincide as they should do; this, as pointed out by Sir William Abney, being due to the very different effect of light of varied intensity upon exceedingly slow plates, the duration of exposure being proportionately altered. On the other hand, in curve M, giving the primary development, the two exposures, though obtained with different intensities of light, combine almost exactly, and a result is obtained as close to the ideal as one may expect to find. There is practically no under-exposure, the least light action shown is correctly represented, whilst anything less is not shown at all. The plate, which normally has but a comparatively short range of correct exposure, is now capable of rendering light intensities of 1 to 1,000 practically correct throughout. The one serious difficulty is that the primary development is so slight compared with the secondary that there is great difficulty in obtaining density.

Passing now to rapid plates it will be sufficient to give a single example, using the most rapid obtainable, as all others will be found to range between these two extremes.

The following differences are found:—

The strength of solution (chromic acid, etc.) used may be ten times great as for the very slow plate.

An under-exposure curve will always be found

The proportion of primary to secondary development, as might be expected, is very greatly increased. With the slow plate at least eight times as much development is required for the primary as secondary in order to obtain sufficient density to measure correctly. With the rapid plate the results of equal time of development are readily comparable.

The limit of the latitude of the most rapid plates has not been ascertained fully, but a correct rendering of light values from 16 to 1,000, or 1 to 2,000, is shown by Diagram 5.

Diagram 5.

Curve N is the characteristic curve of the plate as given by primary development O that due to primary development, and the dotted curve P the difference between the two, which is the secondary development.

As far as exposure 200 the primary is proportionately strengthened intensified by the secondary, but from this point there is a falling off which rapidly increases, and eventually the curves N and O will cross one another, from which point there is no secondary development whatever.

Visible reduction by light alone begins about 8,000, and rapidly increases, and the halogen is undoubtedly liberated, as when a considerable surface is exposed it can be detected by the smell. Though the reduction is not visible before 8,000 it must have begun much earlier, and the liberated halogen seems thus to have hindered secondary development from about 250 in the same way that chromic acid, etc., has now been shown to act, as also bromine in the former papers. Reversal would, therefore, appear to be solely due to the prevention of secondary development in proportion to the amount of halogen released.

Diagram 6.

Diagram 6 is given to show the growth of the two curves with time of development.

Normal development, Q 4. 4 minutes. S 8. 8 minutes. T 16. 16 minutes. Primary development, R 4. 4 minutes U 16. 16 minutes. The primary 8 minutes is omitted to avoid confusion.)

The proportion of primary to secondary is much greater with short (R 4 and Q 4) than long development (U 16 and T 16), which counts for the latitude of a plate and general correctness of gradation always being found greater with short than with long development, so for reversal shifting its position as development increases, as shown by the curves.

We will now briefly consider in another way what light is thrown

upon the theory of the latent image, and finally what practical applications of the method are possible.

Taking Diagram 5, curve M, which gives the most perfect result attained, we find that there is a certain exposure (intensity of light x time) It, which photographically equals 0, and which varies with every emulsion. No intensity has ever as yet been found so small as to be without effect, if sufficient time be given to bring It to the particular value required by the plate in use, from which it would seem that the molecules revert at once to their original condition upon cessation of light action, whenever that particular value is not reached.

In the case under consideration, exposure 1 is approximately Messrs. Hurter and Driffeld's inertia i , which they describe as "that exposure which will suffice to change a particle of silver into the developable condition," and from this point the curve may be calculated by the formula which they give for the correct period of a plate. $D = \gamma \log \left(\frac{It}{i} \right)$, D being the density at any chosen value for It , the exposure, and γ , the development factor representing the amount of development.

This formula is now found to hold good beyond the period of reversal shown by ordinary development, and apparently would extend far further still. Of course, it must begin to fail when the exposures are very greatly increased.

On the other hand, the curve of secondary development (Diagram 6, curve P) obeys no certain law, as it can be easily altered by varied treatment of the plate. It bears some resemblance to the curve obtained when development follows fixing, indicating always a less speed value than the primary ("Photographic Journal," 1898, p. 267), but there does not seem to be any evidence of connection between them.

The intensification of the primary from the surrounding haloids seems to be the more probable action. How far the admixture of different haloids in the plate affects the results has not been investigated.

So far as has been tried with a few developers such as paramidophenol, adurol, amidol, glycin, etc., the different action found is due apparently solely to their varied influence upon the secondary development.

The fact that the silver reduced by primary development is less readily attacked by ammonium persulphate than the secondary, will account for the peculiar action sometimes found with this reducer ("Photography," April 18, 1901, pp. 270 and 271).

With respect to practical applications, that which is most easy to work will probably be found the most generally useful, viz., the control of the gradation in bromide paper printing.*

Papers of the Velox and Gravura type require very thin negatives; but the application of 1 part in 1,000 of potassium bichromate for one or two minutes between exposure and development, will so alter the gradation that a good print may be obtained from a negative specially developed for carbon printing. Very slow lantern plates in the same way will give soft positives from strong negatives.

Passing now to negative making, it is evident from Diagram 2, E and F, that the time and strength of the solution may be adjusted to give any desired latitude and yet secure all the density required, but this must be experimentally worked out first. This and the closely correct result shown in Diagram 5, O, are certainly not much needed in ordinary photography, but should prove specially useful in astronomical work when the contrasts are very great. There are, of course, difficulties to contend with beyond the ordinary method of working, but they do not by any means appear to be insuperable.

JOHN STERRY.

THE Southern Exhibitions.—The dates of the following exhibitions have been arranged:—Hove Camera Club, November 23 to 26, hon. secretary, A. R. Sargeant, 55, The Drive, Hove; Southsea Photographic Society, December 2 to 8, hon. secretary, F. J. Lawton, 20, Clarence Square, Gosport; Southampton Camera Club, December 15 to 20, hon. secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

"SHINING LIGHTS"

A Novel. By Thomas Bedding. 218 pp. Price 1s. London: Published by Strangeways and Sons, Tower Street, Cambridge Circus, W.C.

In this latest addition to the realms of modern fiction one intuitively recognises the method of a master of phraseology, free alike from mannerism and imperspicuity, a method that makes exceedingly pleasant reading.

Dealing with the shining lights of the little Surrey borough of Weyford, Mr. Bedding has in an agreeable manner manipulated his puppets to not only frequently tickle the reader's sense of humour, but to fully regale the fancy for conjecture inherent to the modern novel reader. The character drawing is good; so good, in fact, that we seem to have met with and recognise the types to which the author introduces us. The intrigues of Mr. Fox, the matrimonial affairs of Mr. and Mrs. Armesteen, the domestic infelicities of Sir Rupert Gage, the love passages of Mrs. Dappleton, and the rocket-like ascent and fall of Mr. Varnick, the most brilliant light of them all, have all their prototypes in real life, and, indeed, from the author's ingenuous confession in the preface, are probably to be found in the immediate vicinity.

The reader will soon find out for himself that the story is pleasantly told, with a purity of diction and wealth of expression that has a truly Dickensian flavour. Take, for instance:—

"Joseph was Mr. Minter's Christian name. Mr. Minter himself was a solid, square, middle-aged person of lugubrious demeanour, attired in old-fashioned broadcloth, who might well have passed for an undertaker or the common executioner. His profession possessed some of the chief features of both of those remarkable callings, for Mr. Minter was an auctioneer."

Or, again, the deputation to Mr. Varnick:—

"Shall I open?" said Mr. Redwood to Mr. Minter.
"No, I'll open; you close," said Mr. Minter to Mr. Redwood.
"Gentlemen," said Mr. Varnick, "I am entirely yours."

It was a beautiful spectacle. The Alderman, his right hand thrust into his waistcoat, the left gracefully deposited on the top of Mrs. Dappleton's chair, his head thrown back, and looking straight before him with majestic serenity; Mr. Chantrey standing at a respectful distance, ready with pencil and note-book to record the proceedings. The deputation, literally shoulder to shoulder, in deferential attitudes, and with heads slightly bowed before the chosen one. Alas! that there should not have been at hand, to pass a graphic representation of the episode down to posterity, a painter, a sculptor, or at worst, an amateur photographer. But the world, besides knowing nothing of its greatest men, is also kept pitifully ignorant of the most picturesque incidents that take place in it.

Mr. Bedding's intimate knowledge of the photographic world is betrayed on more than one occasion in the course of the story:—

"Robert had several bobbies, which helped to occupy his leisure moments and yield him in return instruction or profit. He belonged to a photographic society, which periodically met at a free library in South London, and whereat some mighty clever people were wont to assemble and air their own pet theories, to the ignominious confusion of all others, and the unacknowledged aggrandisement of pure knowledge, as distinguished from impertinent nonsense."

The author's easy familiarity with not only the inner circle of the little world he portrays, but his knowledge of matters outside, with a far deeper significance, discloses a keen insight into what is commonly described as "human nature."

The delightful discursive style of much of the work is, however, its chief charm, as the following excerpt testifies:—

"So one evening Mr. Varnick called upon the old man, whom he found unwell; and having referred to his association with Mr. Fox in the latter's venture, hinted that he had come specially to override his lordship's objections in his capacity as Mayor and Member, and was sure that upon reconsideration of the matter his lordship would join them."

The Viscount was (politely) sure that he would do no such thing.

But might Mr. Varnick suggest (looking round) that in his lordship's present unfortunate position the sum offered for the mere right of printing his name—for the chairman's duty would be less than nominal—this sum would be very acceptable?

The Viscount would be obliged to Mr. Varnick if that gentleman would be more explicit.

Mr. Varnick would endeavour to be so. His lordship was, as everyone knew, hard up. That is to say, he needed money, or rather, money's worth—clothes, food, tobacco, wine, and so forth. Now, here was a—

The Viscount would not trouble Mr. Varnick to pursue the matter. He desired to be undisturbed in the management of his own affairs, and was anxious that Mr. Varnick should withdraw from his (the Viscount's) house as soon as it was convenient to him (Mr. Varnick). Mr. Varnick was strongly of opinion that a proposition emanating from the Mayor of the town, who was also its Member in the Imperial Parliament, merited more respectful treatment.

The Viscount could not agree that an official position permitted the commission of confounded impertinence, and evinced his regard for the chosen member of Weyford by threatening his expulsion if—

Mr. Varnick believed that his lordship would be sorry for this. The Viscount requested that the gate might be closed after Mr. Varnick."

As regards the scheme of the book, Mr. Bedding seems also to have acquired the Dickensian trait, somewhat disconcerting times, perhaps, of dividing his dramatis personæ into two or more distinct sets with but a slight bond of union. After eliciting the sympathies of the reader very thoroughly on behalf of set A, the are deserted for many chapters to deal exclusively with the affairs of set B. All the threads are, nevertheless, neatly drawn together in the closing chapters, when villainy is duly unmasked and virtue emerges triumphant. Chapter XXII., "The Iconoclasts," with its dramatic intent, is quite the strongest in the book, and the author would have done better, perhaps, to have written "Finis" hereabouts. The succeeding chapters are much in the nature of a anti-climax for which we are not grateful. The story, however, possesses the desirable quality of holding the attention of the reader throughout, and it is with genuine regret one takes leave of the "shining lights" of Weyford.

We trust that their acquaintance may again be made at no distant date, when Mr. Bedding sees the way clear to take down and publish other occupants of that manuscript shelf in the little Thames Valley study he mentions.

F. J. M.

New Book.

"Jahrbuch des Photographen, und der Photographischen Industrie 1904." Verlag von Gussav Schmidt, Berlin.

We are glad to welcome the second annual volume of this excellent compilation issued under the editorship of Dr. G. H. Emmerich, the Principal of the Munich Photographic Technical School. The work comprises a review of the progress of the past year, with a description of new processes, apparatus, and scientific apparatus relating to photography. There is an excellently-arranged table of chemical indicating the mode of preparation, appearance, solubility, use, etc., and particulars of formulae in which they are embodied. Information upon legal questions affecting the photographer, particulars of the State organisation of the trade, details of the various photographic societies, and a vast quantity of other information, interesting to the professional photographer generally, are given. The volume contains about 500 pages, and is an excellently-arranged handbook not only for the German photographer, but for those who wish for information concerning the art in that country.

Patent News.

The following applications for patents were made between March 2 and April 2, 1904:—

Daylight Developing Apparatus.—No. 7,492. "An improved apparatus for developing and fixing photographic plates and films in daylight." Oskar Zwieback and Sydney Hall.

Bromide Printer.—No. 7,524. "Rapid bromide printer." Harry Jenkins.

Cameras.—No. 7,630. "Improvements in photographic cameras." Charles Howell and George Lloyd Moore, trading as the Midland Camera Company.

Printing Frame.—No. 7,799. "A photographic printing frame." Edward T. Darke.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

7.—Mr. Teape presiding.—Mr. H. W. Bennett, F.R.P.S., a lecture, entitled "Is Time Development Desirable?" The first portion of Mr. Bennett's lecture was occupied with a criticism of his critics, on his lectures and writings on this and other subjects, and disclaimed any intention of making attacks upon individuals, but only upon their teachings. He would be the last man in the world to say anything against mechanical development were it put forward as a guide to beginners, enabling them easily to grasp the rudimentary principles of development, and to be discarded when as they had learnt to distinguish between a good negative and a bad one, but, as the method has been, and is so strongly advocated with the array of scientific arguments and figures as the only method of producing the best possible negatives under all circumstances and conditions, therefore it behoves practical workers to fully examine the subject, and analyse the evidence supporting the theory that is so totally opposed to all their experience. It is highly significant that none of the advocates of mechanical development are experienced workers, and that all of its strongest opponents are well-known for the high technical quality of their work. So the question naturally arises, What value can be attached to the teachings of those whose work is of the poorest description, who deride practical science, and the methods whereby the expert arrives at his results? These mechanical methods are so perfect, why are the results of those who evolved them so poor in technical quality? The methods advocated are all contradictory to each other; one method being to stop all plates for the same length of time, in the same solution, irrespective of exposure, subject, or conditions, only making a variation in time of development when a more vigorous or a thinner negative is required to suit some particular printing process. Another method is to develop for a fixed multiple of the time of the appearance of the image in a uniform solution, varying the multiple if a stronger or weaker negative is wanted. It is also contended by all mechanical advocates that no gain can result from varying the proportions of the ingredients of the developer, that the results obtained by so doing are identical with those given by longer or shorter treatment in a standard solution. As a proof of the non-practical and superficial character of Hurter and Driffeld's experiments and deductions, their method of measuring the amount of light reflected by white and black paper respectively, and their assumption that white paper and black paper would give the whole of the contrast of an ordinary subject, was cited. H. and D. gave the result of that measurement to be 30—as representing the whole amount of contrast the photographer had to deal with; but, as a matter of practical experience,

it would be easy to demonstrate that this assumed maximum is many times greater, and that it varies from at least ten to one up to several hundreds to one, and any one who has studied development practically is aware that subjects that vary in contrast to any great extent, this variation must be compensated for by modifying the composition of the developer, and that it cannot be done by varying the time of immersion in a standard solution. These points were illustrated by the projection of slides of subjects with varying contrasts, not two of which could possibly be developed in the same solution.

Lantern slides of a river scene, a woodland scene, and an interior were projected to show the relative amount of contrast such subjects had, such contrasts influencing the practical man as to his method of dealing with them. Various diagrams were projected, the curves showing that the whole of the image does not appear at the same time, the high lights appearing first, the shadow detail following later. That the image does not grow uniformly, density increasing quicker in the shadows, proportionately, than in the lights; over exposure requiring less time than correctly exposed.

Unfortunately, Mr. Bennett did not conclude his lecture till too late for a good discussion.

Mr. Drage was delighted with the way Mr. Bennett had handled the subject, and had always opposed time development.

Mr. Becket and Mr. Grant entirely agreed with the lecturer. Mr. Rapson could not agree with Mr. Bennett, but, at that late hour, was barred from advancing his arguments. Standard exposures and solutions were very good servants, but had masters.

Mr. Bennett, in replying to the vote of thanks, was sorry not to have met with opposition. As an aid to the beginner, time development was useful, but it failed when dealing with different subjects; it was not possible to develop portraits and landscapes in the same dish and get good results.

All advocates of mechanical development—Hurter and Driffeld, Abney, Sterry, and Watkins, all had different systems, and contradictory one to another.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the General Committee was held at 51, Baker Street, W., on Friday, 8th inst. Present, Messrs. Alfred Ellis, Wm. Grove, F. A. Bridge, H. Edmonds Hull, A. Mackie, Lang Sims, Martin Jarolette, Edgar Scamell, Percy Lankester, and H. C. Spink. Mr. Alfred Ellis, President, in the chair.

A letter was read asking the association to support a member of the public in his defence against a claim made by a photographer for photographs supplied, on the ground that the price charged was unreasonable. The Hon. Secretary reported that he had replied that it was against the general policy of the association to assist the public against members of their own profession, even when not members of the association, unless the case involved unprofessional conduct, and that as the case in point was merely one of price, it could be fought out on its merits. The Committee approved of the Secretary's attitude.

A letter was read from a member asking the Committee's opinion upon a charge made for taking and supplying proofs of two groups and two portraits, all of which had been returned. The Hon. Secretary was instructed thereon.

Other letters asking advice and opinion were also read.

Derby Exhibition.—A report was made as to the promises that had been received to send pictures to the exhibition, and it was decided that as there would still be some spaces to spare, a few of the leading members of the profession should be specially invited to contribute.

The Committee then further considered details of the proposed "Examination of Assistants," and further progress was made.

SOUTHAMPTON CAMERA CLUB.

APRIL 11.—Mr. W. R. Kay gave an illustrated lecture on "The Bernese Oberland." The lecturer conducted his audience from Berne, via Thun, Interlaken, Grindelwald, Meiringen, and Lucerne, to Righi, describing the chief mountain peaks, etc., en route. The lecture was graphically illustrated by a large number of artistic lantern slides, and was full of interest throughout.

RICHMOND CAMERA CLUB.

MARCH 31.—Major Latham gave the club a very interesting lantern lecture on "Scenes in South Africa during the War," embracing a series of views commencing with his departure from this country and terminating with his arrival and decoration at Cardiff. He described the great difficulties a soldier experiences in carrying on photographic work during a campaign owing to his liability to being ordered to start on expeditions at very short notice, the short allowance of water, sometimes limited to one pint per man per day for all purposes, and the small amount of baggage that can be carried when on the march. The gallant Major showed first, pictures of the steamer leaving dock with her decks crowded with men of different regiments, views of Capetown, De Aar, Vryburgh, etc., pictures of horse lines, armoured trains, and numerous arrangements and incidents of the war, all of which he graphically and lucidly described. He gave interesting accounts of hairbreadth escapes and plucky work done by himself and his men. One picture showed a battery he had built which he had only twenty men to serve, covered by the guns from a fort in the rear. During this operation a shell from the fort fell among them. The Major immediately lay down on the ground, and ordered the men to do the same and to await results. Happily the shell did not explode, and it was afterwards discovered that both cartridge and shell were defective. He secured the shell, and had it mounted as a candelabrum. On one occasion, being short of guns, an old-fashioned forty-pounder was sent for his use, but without men to serve it, and the Major had to train men for the work. He showed a photo of the gun taken immediately after firing. The exploding shell could be seen at a distance of four miles—an explosion which caused the death of seven Boers. Four British officers were depicted directing operations, all of whom were wounded within a quarter of an hour after the photo was taken. Another photo showed a Boer who acted as a British scout. On one occasion, when this man was out scouting accompanied by an English scout, they came across some Boers. One old man immediately ran for his horse, and the English scout raised his rifle, but his companion called to him not to fire as the old man was his father, and galloping after him, he secured him, and brought his own father in as a prisoner. Some good views, both above and underground, at the Kimberley mines were shown, including the gun made at the mines, and the tower raised upon the head gear of one of the shafts, from which Colonel Kekewich directed the defence of Kimberley, and which the Boers never succeeded in hitting, although the shells destroyed all the surrounding buildings. Another picture showed the tree under which Dr. Livingstone is said to have proposed to Miss Moffat, and which bears a brass plate recording the occurrence affixed to it by a native admirer. Other interesting views showed the makeshift houses in which the Major lived on the field, in the construction of which old biscuit tins played a useful part. Major Latham concluded his photos with pictures of native women in their national, but somewhat scanty, costume, including two daughters of King Khama, one of whom wore nothing more than a pair of soldier's puttees, and whose value is assessed at forty cows, and after his lecture he showed some interesting relics, including pieces of shell, unexploded shells, bullets taken from wounds, emergency rations, Mafeking siege notes, specimens of native carving, etc.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE annual general meeting of this society was held on Wednesday evening, April 6, in Collyer Hall, High Street, Peckham, the President, Mr. Maurice Howell, presiding. The secretary, Mr. W. Calder Marshall, in reading his report, gave an excellent resumé of the society's work during the past year, showing that the South London was in a flourishing condition. All who were present knew what an excellent and most popular secretary Mr. Calder Marshall had proved himself to be, and they were very sorry to hear him state that owing to the increased demands of his own business affairs he would have to relinquish the secretarial post. His resignation was eventually accepted with much regret. The reports of the excursion and portfolio secretaries having been received, the treasurer, Mr. C. Churchill, presented his report and accounts for the year ending December 31, 1903, showing a very satisfactory balance on the right side. Several items of expenditure were, however, attacked by various members, and a long—and, at times, heated—discussion took place;

two resolutions embodying more or less drastic reforms being put to the vote during the evening, and rejected—one by a majority four only. Under the present régime of the Society the President is elected annually by ballot. The announcement that Mr. C. Dickinson had received the largest number of votes, and was the first President for the ensuing year, was received with much applause.

The new President, in addressing the members on the policy should pursue during his term of office, said he was afraid that with regard to a number of the functions of the society some of the members were very apathetic, and he would consider it his duty to awaken them from their lethargic condition, so that they might realise their responsibilities as live members to uphold the prestige of the society had gained in the past, and to help it achieve further successes in the future.

As a mark of the society's appreciation for the work of Mr. Calder Marshall and Mr. C. W. Walker (who had much to do with the success of the 1903 exhibition), these gentlemen were elected vice-presidents—a perpetual post of honour.

The new secretary is Mr. H. C. Beckett, of 44, Edith Road, Peckham.

THE KODAK EXHIBITION OF PHOTOGRAPHS OF THE FAR EAST.

THE Kodak Co., with their usual perspicacity have made the current interest in the affairs of Japan, Korea, and Russia the excuse for bringing together at their Gallery, 59, Brompton Road, S.W., a very presentable collection of pictures illustrative of life and customs in these far-off regions. So far, the Press censorship and delay in transmission have been responsible for the fact that no spoils of war have filtered through from the seat of war, so, although the intention of the present collection is mainly ethnological and geographical in character, and beyond the representations of various battleships and an occasional military type, the motif that distinguishes the pictures is undoubtedly a peaceful one. Of course, the chief claim for attention to the collection is that the pictures were taken on Kodak films with Kodak cameras, and, needless to say, the ubiquity of the firm's goods is again amply demonstrated. The pictures included in this exhibition are all enlargements made on Kodak bromide papers of various grades, and although a slight variation has been made to the plan adopted in the Kodak itinerant exhibition—i.e., the framing and selection of printing process show more variety—the result is even now a trifle monotonous. The original negatives from which the prints are made were taken principally by Messrs. Walton Hill, Percy B. Rowe, J. L. Sudbury, D. Vaughan Cornish, and Dr. H. W. Bayley. The exhibition, which remains open for some time, is well worth a visit, and every visitor will receive every attention.

MESSRS. C. ABLARD AND Co., photographic dealers have been compelled, on account of increase of business, to remove from Colebrook Row, to larger premises at 240, Upper Street, Islington (opposite the Agricultural Hall), London, N.

MR. JOHN B. HADDOW, the well-known manufacturer of cinematograph films, has recently joined the British Mutoscope and Biograph Company, of 18 and 19, Great Windmill Street, London, W., in a managerial capacity. We wish Mr. Haddow success in his new position.

WE are in receipt of a comprehensive little price list from the London and District Photographic Co., 16, West Ella Road, Willesden, N. The company makes a speciality of printing and enlarging, and an excellent specimen of their work—a first class portrait on Wellington rough bromide paper, adorns the inner cover of the price list.

CEYLON at St. Louis Exhibition.—Mr. A. W. Andree, of the Houton Studio, Ceylon, is well represented at the St. Louis Show. He is contributing seven fine specimens of photographic work—typical of Ceylon, and as perfect and finished as could be found in any modern studio. All are of important size, the largest, representing the return of a pearl-fishing fleet, taken off Marichchikadde, 50 in. by 40 in., and is finished in colour, and none are smaller than 40 in. by 30 in. They should prove not the least attractive and alluring of the many advertisements of our island colony to be exhibited in the Ceylon Court at St. Louis. Mr. Andree is to be congratulated on the excellent work he has turned out.

Correspondence.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

We do not undertake responsibility for the opinions expressed by our correspondents.

"CINEMATOGRAPH PATENTS."

To the Editors.

Gentlemen,—In your issue of April 8, under the heading of "Cinematograph Patents," you take occasion to comment adversely upon my name to be the original inventor of the cinematograph, and mention my inventions as anticipating my own in this line. I am surprised at a journal of your standing should mention Beale's Choreutoscope, Phenakistiscope, and Muybridge's Cameras as cinematographs. They are not cinematographs in any sense, which you should know. Beale's Choreutoscope did not use photographs at all, but painted figures, similar to those used in the old Zoetrope, and the process of producing and showing these figures was entirely different from that used in my cinematograph. The same remarks apply to the Phenakistiscope. Muybridge simply used a series of cameras, which took successive pictures of an object in motion. The vital difference between his invention and mine is that all of the photographs taken by my cinematograph are taken from one point of view, by merely turning a handle, whereas Muybridge's pictures were taken from different points of view, and did not produce an animated picture as we see it in nature, which my camera does.

Possibly you would kindly tell me how you would produce a modern cinematograph picture without making use of my invention. For my part, I do not make use of any of the inventions you mention in producing my results. It may be true in a sense, that, as you say "the principle of the modern cinematograph machine" is found in some of these inventions. On the same theory the "germ of the steam engine" is said to be in the tea kettle. If this astonishing doctrine was carried out, there are no real inventors in modern times.

I therefore feel that I am entitled to claim to be the original inventor of the cinematograph, and that my patents of 1889 and 1893 are the basic patents on this invention. Until you bring some more cogent arguments to bear, I will continue to make this claim. You intimate that statement that celluloid was not made in long lengths prior to 1889, therefore could not be used for cinematograph films is unwarranted. I know of no firm or person prior to that date who made celluloid in long lengths or used amyl acetate for joining short lengths together. If you do I would be pleased to have you give names. You intimate in your article that I am trying to belittle the inventions of others. That statement I resent as unwarranted and unjust. I have never wittingly claimed the benefit of another man's invention, but have cheerfully acknowledged my indebtedness to anyone who has even suggested an idea which I have perfected. On the other hand, I have resented and surprised and grieved to think that a journal of your standing should make such unwarranted insinuations as you do in your article referred to. In justice to me, I trust you will give this letter the same publicity as you have given to your own.—Yours, etc.,

W. FRIESE-GREENE.

Millbrook," Dovercourt, April 8, 1904.

SOME NOTES ON THREE-COLOUR WORK.

To the Editors.

Gentlemen,—I am obliged to Mr. Baker for pointing out my obvious error of "red" for "blue," as he does on p. 289 of your last issue, in his article under the above title.

I am in rather a quandary as to whether the rest of the article is to be taken seriously or as a mere trifle thrown off in an idle hour; whilst referring to "guides" and "authorities," Mr. Baker himself claims, possibly unconsciously, to be an authority, particularly when he states that dry-plate should undoubtedly be panchromatic. To me this is as the authoritative statement that the one-plate system is the only one, but this is not universally admitted.

The next paragraph, beginning "a great deal of confusion, etc.," is, I do not help thinking, somewhat egotistical, and the latter half shows ignorance of facts, without which it would otherwise border on the

impertinent. On the principle that "qui facit per alium facit per se," Dr. Eder, as the head of the famous photographic school in Vienna, has probably done more than any other man living not only to give us new sensitizers, but to prove their practical value; yet Mr. Baker wants Dr. Eder's experiments proved or disproved.

We now come to the use of Wollschwarz 4B, and other dyes, and it is a pity that, having Dr. Eder's recent work, by which, I presume, your correspondent means "Die Grundlage der Photographie mit Gelatine-Emulsionen," 1902, that he did not refer to it before he wrote his article; and that having von Hübl's "Die Dreifarbenphotographie," he did not refer to this also. Dr. Eder states, in a foot-note, on p. 190 of the said book, at the conclusion of his notes on the sensitising action of the dyes in question, "The numerous three and four colour prints which the K.K. graphische Lehr u. Versuchsanstalt of Vienna exhibited at the Paris International Exhibition, 1900, and which showed very correct colour effect, were produced by the sensitizers here described; the plates behind the red filter were sensitised with nigrosine, wollschwarz, or diazoschwarz."

Baron von Hübl in his work, 1902 edition, p. 122, says: "There is no doubt that the results obtained with a diffraction spectrograph, render possible a correct opinion as to the practical colour sensitiveness of a plate, but the spectrum is rather faint, and the little action of a plate, but the spectrum is rather faint, and the little action of the less refrangible rays, which directly interest us, can be easily overlooked. If, for instance, a red sensitive commercial plate is exposed to the diffraction spectrum, its red sensitiveness does not show at all, so that one might consider it a non-orthochromatic plate, and yet behind a suitable filter and sufficiently long exposure it may reproduce red pigments distinctly."

As regards Mr. Baker's statement that both his plates were foggy, Dr. Eder includes in his original treatise, a foot-note to his formula, which I did not abstract, to the following effect:—"Many bromide plates give fog with ammonia in the dye bath; then this addition should be omitted and cleaner but less sensitive plates are obtained. The preliminary ammonia bath is, however, then all the more necessary, and ought not to be omitted." Obviously, therefore, Mr. Baker used an unsuitable plate.

I leave to Mr. Baker the task of explaining why, if cyanine is such an extremely satisfactory sensitizer, so many experiments should be made to get rid of its use. Again it is fair to drag in orthochrom T., which, in 1902, the date of Dr. Eder's treatise, was unknown.

Turning now to Mr. Baker's own work in the shape of the spectrograms, I admit at once that it is extremely unfair to judge from half-tone reproductions, but as he has published these as proofs we must accept them as the basis for criticism. In the first place the only indication as to the colour distribution is that "the red end of the spectrum is on the left-hand side," we have neither millimetre, nor wave-length scale. We have no spectrogram of the undyed plates, nor results by Dr. Eder's formula, no cyanine results to substantiate the statement that wollschwarz gives only a fraction of the sensitiveness of cyanine, and no measurements as to the relative densities in any section of the spectrum, and fig. 2 simply shows that this particular spectrogram has a higher development factor, or that the light varied, or that the plate has not been sensitised at all.

If Mr. Baker will find a suitable plate and make a series of experiments supplying all the necessary data which are certainly missing in his article, as to the uselessness of the dyes he mentions, I might—perhaps—accept it against the evidence of such expert experimentalists as Dr. Eder and Professor Valenta, and against the three and four colour prints produced by the Vienna school with plates sensitised with these dyes.—Yours faithfully,

E. J. WALL.

Foots Cray, April 9, 1904.

"KEEPING QUALITIES OF DRY PLATES."

To the Editors.

Gentlemen,—In "Cosmos' Jottings" in your issue of March 25, I observe you ask for further experiences of the keeping qualities of dry plates. I obtained a packet of 5 x 4 Extra Rapid from R. W. Thomas and Co. a great many years ago. Batch No. 7,928, but as I had not written the date of purchase on the box when I received it, I could not now tell the year. However, I wrote Messrs. Thomas, and enclose their reply. The box had been opened and some of the plates used within a few weeks of purchase, and the rest had been put aside without any special care.

After reading your notes I exposed one of the plates on a white marble mantelpiece and enclose a print from the negative; it has been rather under-exposed, but there is no fog except a very little on the extreme margin of the plate. It was developed with pyro ammonia. I have still three or four left of the batch, and will have no hesitation in using them. My experience is that the dry plates made by reliable makers ten or twelve years ago were possibly more carefully made, with a view to keeping qualities, than many of those now put on the market, when the tendency is to cheapen the price at the expense of quality. Some ten years ago I laid in a considerable stock of Wratten and Wainwright's "Ordinary" (slow) to take away for a trip, which, however, did not come off; these I am using regularly now, and find them as clear as if newly made; indeed, I use them for making enlarged negatives from 4-plates, and they are without a single fault; the latter firm I find have more paper wrappers round them than any of the others use, and possibly this prevents deterioration.

I have found that the earliest make of Iso plates do not keep well, but perhaps this is remedied now, but time will show.—Yours truly,

DAVID IRELAND.

12, Douglas Terrace, Broughton Ferry, N.B.

April 8, 1904.

[COPY.]

To David Ireland, Esq.

Dear Sir,—In reply to your letter of yesterday, we regret to say we cannot give you the exact date of manufacture of the plates in question, as we do not preserve the records after ten years, but as far as we are able to say, the batch you mention was made about twelve or fourteen years ago.—Thanking you for any trouble you are taking in the matter, we are, dear sir, yours truly,

R. W. THOMAS AND CO., LIMITED.

Pall Mall Factory, Thornton Heath.

[We have examined the photograph sent us by Mr. Ireland and find it shows no signs of having been taken on a stale plate. The print is apparently from a clean and crisp negative, showing good gradation and lack of fog.—Eds.]

PICTURE POST-CARDS.

To the Editors.

Gentlemen,—We notice in current issue of your paper, under "Answers to Correspondents," a reply regarding picture post-cards to "W. M." We beg to inform you for your future information that we are pleased at all times to purchase negatives of suitable subjects from photographers. We shall be pleased to supply you with any particulars at all times.—Yours faithfully,

THE PHOTOCROME COMPANY, LTD.

35 and 36, Hosier Lane, Snow Hill, E.C.

April 12, 1904.

THE INFLUENCE OF THE CHEAP HAND CAMERA.

To the Editors.

Gentlemen, Do you not think it would be about time now to sound another tune from what we have been accustomed to hear lately? Nothing but praise has been heard, especially in the advertisement columns, about instantaneous or detective cameras. Without wanting to detract anything from their usefulness in some respects, and for some purposes I think they have come to be looked upon as something universal, not to be improved upon. For portraits they are just the thing, and as good as any specially constructed camera and lens; for views nothing can excel them, always in focus giving depth and sharpness. For architectural subjects, any child can, with one, take a cathedral or a castle, interiors, etc., just as well as any professional can do after years of experience. As for instantaneous views of railway trains, steamers, jumping horses, etc., who will admit that he has not done it or can do it at any time? The only difficulty is in getting the subject in the right place on the plate or film, but I think the party unable to do this is not born yet, or maybe he is dead long ago. The fact is, however, that very few do really succeed with this instantaneous business, and the parties who have bought the outfits if they want to meet with good success and want to go on in that line, use a tripod and study their exposures, and then, after a little practice, get a larger and increasing percentage of good negatives. Experienced parties know very well that it is a very difficult matter to expose not only correctly but about correctly when one has to take views in all

kinds of weather or wishes to take these views even when they are all exterior views in open air. And particularly so when one has two or three diaphragms in the lens, and exposures varying from 1/10 to 1/100 of a second. In print it sounds all very well, but how different reality. I have seen, and probably others also, individuals taking views with detective cameras in winter at 4 p.m., of a train passing, another one will take in dark weather a 'bus at full speed, and a clever party try his luck with one or two seconds exposure, camera in hand on an old and dark painting in a room.

Who is to blame for this? This is a big question to answer. Of course one cannot say all this to a customer who wants to buy cheap or inexpensive outfit, and wants, after all, to spend as little as possible generally, and have a light camera containing all improvements possible and sometimes impossible. The manufacturer wants to sell and supply the demand, let afterwards happen what may. The retail dealer wants also to sell as much as possible, and general knows more or less (rather less) about what he sells, says everything as easy as can be, receives his money, and says good-bye. Sells future a few extra films, some chemicals, sometimes develops a certain quantity of failures, prints some foggy and out-of-focus proofs, and that ends it for that party. I am not poor yet I am not rich, but how often I think, I only wish I had the one-hundredth part of the money that has been paid out for outfits which, after a very short trial have been discarded and put in the garret, if not in the cellar, to rot.

The fact remains that this demand which has been created by advertising such "good-for-everything," detective, or other similar cameras, has spoiled the demand for good, real good, and useful portable cameras to be used with tripod, to such an extent that not only no improvement on such is made, and the demand for them diminished, but the manufacture of them has been abandoned by some first-class firms, so I have been told.

Is photography really improving with such a state of things. I have my doubts about it. A few shillings, and maybe pounds, are made by it, but in the end what will be the result? It should be borne in mind that all things pass, especially novelties. Everything has its time, and, as they say in France, "Un clou chasse l'autre." The next novelty will push this one (instantaneous boxes) in the shade, more or less, if not altogether. But not to go to extremes, let us admit that it will remain as it is now for say ten years more. What will be the result photographically? Large and fine photographs will not be seen anywhere, except as mere curiosities, and by large I do not speak of 15 x 12 or 12 x 10, but probably as low as 10 x 8 or 8½ x 6½. Who nowadays willing to carry a camera as large as 6½ x 4½? Very few indeed, and 3½ x 4½ is more commonly met with than anything larger. Result, an army of pigmy photos. There could be a possible salvage point somewhere if these views would be sharp in focus, and could be enlarged, at least to 10 x 8, but how many will stand this trial? Mighty few, and these lessened yet when the foggy ones, over-exposed, or under-exposed ones, out of focus or out of range, are deducted. Of course all modern cameras have lines marked for different distances, but these are not marked with each lens as they should be, every lens having a different focus (if not, why ask 10s. more or less for pairing stereos). Supposing this marking to be correct, what is the man that can say exactly straight in front of him ten yards from twelve or eleven, or, better yet, twenty to thirty. Then, where is sharp focus for enlargements. Supposing that this is judged correctly (a first-class instrument being used of course) taking now, for instance, rather high building. How can the tilting of the back be judged correctly by the finders and kept so for exposure. In this case the many things to be looked at to get the picture just right is certainly more troublesome than the use of a light tripod to make sure and certain of a good and first-class picture. We all have seen the beautiful results that can be obtained by any one (even by animals) allowed to press the button with So-and-so's cheap outfit of only a few shillings, and you can start and have equally good results. And so it is. The proof of it are the pictures shown you, and which have invariably been taken with an outfit similar, and just by chance by an amateur on his first outing, developed and printed by himself, and which has graciously offered it. You don't doubt this. Do you? It never enters your mind that this or these views shown to you as beginner's results may have been made with another camera, and another lens, on tripod, by a good operator. No it does not, and it must not, as it is not the case. Amen! But supposing you do not succeed as well as the samples shown, who is to blame but you. You may not think so, but

u don't know better to answer not being acquainted enough with photography and its "tours de batons," and try and improve, or, as d before, put the whole thing aside. The moral of this should be. Everything in its place, and for special work use special cameras. Instantaneous cameras are very good for special purposes and results wanted, t they are not and cannot be universal. If you want good instantaneous views of moving subjects, then an instantaneous camera and is a necessity, however not necessarily without a tripod. But if u want landscapes and seascapes from shore, buildings, interiors, t, then a regular camera with bellows and variable focus is certainly ch superior to the former. I may even add that it is much easier to with a regular camera, swing back and rising front and a finder, all t can be made with any instantaneous camera than the reverse.—I main, dear sirs, yours very truly,

ALBERT LEVY.

4, Avenue Pinel, Asnières (Seine), April 7, 1904.

THE ENSIGN FILM COMPETITION.

To the Editors.

Gentlemen,—We shall be glad if you will draw the attention of your orders to the fact that the Ensign Film Competition, for photos taken any camera with the "Ensign" or "Ensign Vidil" daylight loading film, closes on May 30 next. One hundred pounds divided into ninety-two prizes of from 10s. to each will be distributed among the various classes. We shall be d to send full particulars and entry forms to any of your readers who d send us a post-card.—Yours truly, HOUGHTONS, LTD. 88 and 89, High Holborn, W.C., April 11, 1904.

KEEPING PROPERTIES OF FILMS.

To the Editors.

Gentlemen,—It is frequently stated that films will not keep good long as plates, but the following shows that some films, at any e, will keep in good condition quite as long as any plate. In July, 1889, I had sent me a sample packet of two films, by e. Place, 13, Bull Street, Birmingham, of "Anthony's Climax ative Film," sensitomer No. 28. No instructions for developing e given, and as I was at the moment developing some Imperial inary plates, I used the same developer for the films. The subject was the same for each, a copy of a photographic portrait myself, exposure 15 seconds at f.32 for the plate, and 30 seconds f.32 for the film, the exposures being made immediately one after other, in a fairly bright light, by the vertical method, in front a window. The resulting negative was almost as good in one case as in the er, indeed, in some respects, the film gave the better results. I did not take any special pains with either negative, the only ect being to see how the films kept during the fifteen years I d had them. Probably these films are no longer to be obtained, as I do not them quoted.—Yours faithfully, J. H. BALDOCK. Croydon, April 12, 1904.

PSYCHIC PHOTOGRAPHS.

To the Editors.

Gentlemen,—I quite think with you that the cause of truth will be t served by open correspondence respecting the alleged photographs spirit forms, and if Mr. H. Blackwell or others can kindly give us y definite information as to how to obtain results similar to those has secured it will be very interesting. Not being acquainted with ritualistic matters I cannot conceive how Mr. Blackwell can know y spirits find it necessary to wrap themselves in an "aura," nor do now anything of animal magnetism, but when a collection of alleged rit photographs was published a while ago, I knew enough of rography to see at once that the originals had been lighted by a m of light in the orthodox studio manner, with lights and shades as al when sitters in the flesh are photographed, which, to say the est of it, is very remarkable. The statement that results are scme- es obtained by simply holding a plate in the hand without the use of camera (in which statement I suppose the non-use of any lens is

included, also that the plate so held is in darkness), is very upsetting to my optical ideas, and seems to prove that the ghostly visitors have some wonderful power of impressing their forms on photographic plates quite different from our everyday practice. Possibly a photo- graphic plate is unnecessary also, and I would suggest that the spirits be supplied with plain white paper on which they may draw their images with far less difficulty than having to impress them on a photographic plate without a lens to focus the rays or emanations, or whatever it may be that is supposed to render the silver bromide of the plate capable of development. Perhaps, however, I am wrong in supposing development is necessary at all. Can it be possible that the spirits have the strange power of impressing their images in a visible manner on a photographic plate simply held in the hand in darkness? If so I fear the suggested demand for cameras (with lenses) will be small, as if I could only find a way to obtain the images of my mortal sitters without the bother of focussing expensive lenses and carrying a bulky camera about, I should be very happy to dispense with such encumbrances. Hoping that much light may be thrown on this dark subject, I remain, yours truly, E. WILLIAMS.

REMBRANDT Art Company, Limited.—This Company has been regis- tered with a capital of £1,250 in £1 shares. Object, to acquire the business of a portrait painter, photographer, and fine art publisher carried on by J. W. Jameson at 8, Peck Lane, Nottingham, as the Rembrandt Art Company. No initial public issue. The first directors (to number not less than two nor more than five) are J. W. Jameson and A. Waddams. Qualification, £50. Remuneration, £5 each per annum. Registered office, 8, Peck Lane, Nottingham.

AUTOMATIC Cinematograph Advertising Syndicate, Limited.—The above-named Company has been registered with a capital of £10,000 in £1 shares. Object, to acquire the benefit of certain existing inven- tions, to adopt an agreement with R. G. Fothergill, and to carry on the business of cinematograph and automatic machine proprietors and manufacturers, advertising agents, etc. No initial public issue. The first directors are H. Mann, F. Allen, and R. G. Fothergill (managing director, with £350 per annum). Qualification, £100. Remuneration, £50 each per annum and a share in the profits.

CROWN Art Society, Limited.—The above-named company has been registered with a capital of £2,000 in £1 shares (1,500 Preference). Object, to acquire and carry on the business of fine art dealers, photo-reproducers, photographers, electrotypers, printers, publishers, etc., now carried on by A. B. Nielsen and A. L. Ponting at 9, Regent Street, W., as the Crown Art Society. No initial public issue. The first directors (to number not less than two, nor more than three) are A. L. Ponting and A. B. Nielsen. Qualification, £1,000. A. L. Ponting and A. B. Nielsen are joint managing directors with £100 each per annum. Registered offices: 50, King Street, Regent Street, W.

HULL Photographic Society.—The twenty-first annual report of this society is to hand, and shows steady progress made during the past year. The books record a total membership of 289, and the finances of the society are in a satisfactory condition. The officers for the ensuing year are: President, Mr. W. S. Parrish; vice-presidents, Messrs. R. E. Johnson and G. F. Bristow, junior; hon. treasurer, Mr. D. L. Cockcroft; hon. solicitor, Mr. R. E. Johnson; hon. lanternists, Messrs. W. Dalton and T. Frazer; librarian and editor, W. Gilleard, 11, Clumber Street, Hull; hon. curator of en- larging, Mr. H. Strong; hon. secretary, Mr. A. E. Hindson, 6, Free- hold Street, Hull; Council, Messrs. Rev. C. O. Stewart, F. Atkinson, T. J. Hards, F. Woollons, and Hewat Fraser. The summer syllabus is to read, one meeting first Thursday in each month, and an excu- sion every alternate Saturday afternoon. Much time and care has been expended upon fixing up the latter so that they will suit all members as far as possible. It is the intention of the President and the Council to do all in their power to encourage the younger members in the pictorial element and composition, as well as maintain the social side of such outings. There is every possibility of the Hull amateurs having a good and profitable time during the summer of 1904. The first excursion is on April 23 to Wakefield, to the annual meeting of the Y. P. U. Then follows: Westella, Ferriby and Welten, Barrow and its haven, Howden, Burton Constable (picnic), Flambro and Bridlington, Fountains Abbey (all day), Newbald and Houghton Woods, Burton Stather, Beverly, Pauli, and Patrington.

Answers to Correspondents.

- All matters intended for the next portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- J. D. Shiels, 9, Marchmont Street, Edinburgh. Photograph of *Str Robert Cranston, V.D.*
 E. Smith & Sons, Quorn, Loughborough. Photograph of *Quorn Hounds.*
 H. J. Penny, Fairfield, Leatherhead. Photograph of *A. Shrub.*
 E. G. Harries, Alma House, Bishop Street, Londonderry. Photograph of *Band of 1st Royal Inniskilling Fusiliers.*
 P. H. Hilson, 4/A, North Street, Brighton. Photograph of *Drawing, Land'slip at Blackrock, Brighton.*
 A. F. Dawkins, 12, West Cliff Road, Ramsgate. Photograph of *the Colonnade at Ramsgate, now Demolished.*

JAS. CULNAN.—There cannot possibly be any objection to the change of name.

COPYRIGHT QUERY.—S. T. W. You will find the subject of your letter dealt with in an article in another column.

PICTURE POST-CARDS.—"BROMIDE" says: "Will you, please, tell me if you can recommend a reliable 'bromide printing machine' suitable for post-card work?" In reply: Messrs. Marion and Co., 22, Soho Square, London, we believe, supply a bromide printing machine. Other large dealers, no doubt, do so as well. Write them for particulars.

BROMIDE PROCESS.—"WORKER" asks: "Would you kindly let me know by what process the enclosed midget is finished, as you will notice the name and address is printed with the photograph." In reply: The process by which the print was produced is the gelatino bromide. It is simply printed on a paper of the "Velox" type, and developed in the usual way.

ADDRESS WANTED.—J. SPENCER writes: "There is a maker of photographic burnishers either in Germany or Austria, called Carl Seel. I will be much obliged if you can oblige me with his address." In reply: We regret that we cannot give the address as we do not know it. Perhaps some reader who does will be good enough to supply the desired information and oblige our correspondent.

RADIUM.—"RADIUM" asks: "Would you kindly inform me whether the 'metal radium' is a thing that can be seen, and whether there is any book published on the subject, as I am anxious to have one?" In reply: You should consult the new book entitled "Radium and All About It," by S. R. Bottone. Published by Whittaker and Co., 2, White Hart Street, Paternoster Square, E.C., at 1s. nett.

TINTING PAPER.—"GELATINE" asks: "(1) What is the best soluble aniline dye, unaffected by acid, most suitable for tinting mauve and pink, gelatine P.O.P.? (2) Also, what will best remove the natural yellowy tint of the gelatine, for white P.O.P.?" Reply: (1) Any of the soluble colours will answer, but get a list from any of the agents for coal tar colours, and from that make your selection. (You could get the addresses from any dye works.) We are not in the secrets of the paper makers, if there is any secret in this? (2) If you use a colourless gelatine there should be no yellow tint.

COPYRIGHT OF DESIGN.—J. C. BROWN says: "I have been thinking of a new mourning envelope, and my idea is this: Instead of a

black border to have simply three, two, or one black line (according to degree) across the top left corner. Will you kindly say, through your 'Answers to Correspondents,' if I could copyright this, or if it would have to go through the patent office. If it was the latter, I am afraid it would not be worth it? I enclose an envelope to show my meaning." Reply: "You might possibly register the thing under the Designs Act, or even patent it, but we are not sure on the point. We have the idea that we have seen the same thing before.

PHOTOGRAPHY IN SOUTH AFRICA.—"ASSISTANT" writes: "In your last issue 'A Scotchman in Natal' gives an interesting account of 'Photography in South Africa,' but some information as to living expenses would also have been valuable. He mentions the case of an assistant who went out to Natal under a three years' agreement, but who received three months' notice to quit, presumably after being there a short time. Surely his references, etc., would have been a fair guide as to his ability before the South African firm decided to transport him 7,000 miles from England. Is the agreement no protection to the assistant?" Reply: We, of course, know no more than is contained in the letter of the Natal writer. We presume that, as in England, an assistant misrepresents his abilities an agreement for service may be cancelled in South Africa.

LENS QUERY.—F. N. says: "(1) I have a well lighted studio; not too light; length from sitter to camera, farthest distance, 21 ft. What sort of a lens would you advise me to get for portraits? I should prefer a very quick lens. (2) Should I require different lens for head and shoulder work, groups, young children, etc. (3) The one I have been using I fancy is too slow. I can only get satisfactory results in a first-class light, and seem at a loss if the light is only moderate. Can you tell me if it should be suitable for my work?" In reply: (1) The most generally useful lens in a studio of that length would be one of about twelve inches focus. (2) No, except, perhaps, for very small pictures, when a shorter focal lens would come in useful. Or if large heads are desired, one of longer focus would be desirable. (3) The lens you have is very slow as compared with a portrait lens. It requires about four times the exposure necessary with, say, a quick-acting cabinet lens.

PRICES.—C. J. K. writes: "(1) I should be much obliged if you would give me your opinion of my work, of which I enclose three specimens (1, 2, 3); also if you will answer the following: I have been asked to supply a printer with 1/2-plate photographs of various buildings, in different places, for reproduction as post-cards. (2) What do you consider a fair price (travelling expenses extra) for 1/2-plate architectural photographs, interior and exterior, the work being of same standard as enclosed No. 1? (3) Ditto, ditto, for animal studies." In reply: "The prints sent are good. (2 and 3) We really cannot undertake to tell photographers what they should charge for their work. They are certainly better able to assess its value than we possibly can be, seeing that so much depends upon circumstances, time occupied in travelling, etc., etc. Why not become a member of the Professional Photographers' Association? Full information will be found in 'Photography for the Press,' obtainable from any dealer in photographic literature.

•• NOTICE TO ADVERTISERS.—Blacks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Testing the Result.
It is sometimes remarked of a person who shows symptoms of irritation without any apparent cause that he, or she, must have "got it out of bed on the wrong side." Perhaps this accident may have happened to the writer on the staff of the "Times" whose lot it was to review the action of the Worshipful Company of Spectacle Makers in instituting a diploma in the art of sight-testing. He devotes quite a third of a column to denouncing the scheme, and towards the end of his fulmination writes that "it would not be unreasonable to require that the power to issue 'diplomas' of any sort should be subject to the control of some responsible body in the State, and should not be exercised at their own discretion by trade companies, even after they have been approached in the manner indicated." The sting of his last line lies, like that of the wasp, in its tail, for "the manner indicated" refers to the several well-known names. Now what have the Spectacle Makers' Company been guilty of to earn this abuse? After a long inquiry by a Committee which was presided over by Sir George Faudel-Phillips, a Committee which had the assistance of Counsel and of Professor Sylvanus Thompson as assessor, a Committee which took evidence from representative medical men and members of the optical trade; after the opinions of this Committee had been backed by a memorial which was signed by Lord Kelvin, the Earl of Rosse, Sir William Crookes, Sir William Abney, and other known scientific men, the Company decided to institute the diploma. If this Committee, working under the conditions described,

did not constitute "a responsible body," it is difficult to understand what is meant by that term. And, after all, the diploma does not give the opticians more power than they had before. It simply means that those who hold it are skilled men, as distinguished from quacks, and it is for the protection of the public, and not for the sake of the opticians, that the diploma has been instituted. Why the writer of the "Times" should have taken up an antagonistic attitude on this question, except on the wrong-side-of-the-bed theory, it is very difficult to discover.

* * *

Unreliable Shutter Speeds.

A little while ago we called attention to the unreliability of the speeds, as marked on the indexes, of the majority of the shutters fitted to hand cameras. In our last issue we reproduced an article, by Dr. Hans Lehmann, in the "Instrumentenkund," on the speed measurement of shutters and the method of testing adopted by the author. The paper will be found on page 310 ante, and it proves the discrepancies there are between the asserted speeds and the actual ones even in the shutters of the best makers. The method of testing adopted by Dr. Lehmann is a somewhat novel one, and it may be a somewhat open question as to whether it is really better than some other methods of testing shutter speeds. But as all those examined were tested under similar conditions, it seems to show that their speed indexes are not to be depended upon for the actual time the plate is exposed. The table appended to Dr. Lehmann's paper is interesting as showing the wide difference there is between the index numbers and the actual speeds of some of the most renowned makers in Germany, America, and England; and it is satisfactory to learn that the palm is taken by an English one—Newman and Guardia's. Of this the author speaks very highly, which, he says, "had been in constant use for two years, and the figures given show that it was the only one of those measured that worked to its indicated speeds." Although, of course, it is most desirable that the marked speeds on the indicator should be correct and reliable, which most of us know is seldom the case, still, as we said in the previous article on the subject, it matters very little in actual practice whether they do so or not so long as the worker knows that when his shutter is set at a certain alleged speed he gets the exposure he desires, whether that be a tenth, fiftieth, or the hundredth of a second. One often sees on pictures exposure so many fractions of a second, but what actual information does that convey beyond the fact that the index of the particular shutter used was set for that speed? And the user assumes that it is correct, while, as a matter of fact, the actual exposure the plate received might be widely different—above or below—as practical speed tests usually prove.

Foreign Chemicals.

In its last week's issue the "Pharmaceutical Journal" refers to a rumour that in the forthcoming Budget the Chancellor of the Exchequer would probably put a tax on foreign chemicals, or such of them in the manufacture of which alcohol is employed, although they may not contain any spirit. Our contemporary, after commenting on the fact that in Germany duty-free spirit is allowed to be used in manufactures, and this costs but twopence a pound, whereas the British manufacturer has no such privilege, and has, perforce, to pay two shillings and threepence a pound for the same thing. Of course, under these conditions, the English manufacturer is very heavily handicapped. The "Pharmaceutical Journal" points out that no new law would be required for this tax, as it will only require the enforcement of an Act already twenty-eight years old, namely, the Customs Consolidated Act, 1876. One clause of this Act reads thus: "Upon the importation into Great Britain and Ireland of any article in the manufacture of which spirit has been used there shall be charged in respect of such quantity of spirit as shall appear to the satisfaction of the Treasury to be used in the manufacture of such articles a duty equivalent to that which would be chargeable on the like quantity of spirit on its importation into the United Kingdom." At present there are only about eight articles which are taxed under this clause, but there are now a large number more that could now be so taxed—some of the coal tar colours, for example. If that were done the Customs revenue would be increased, while the British manufacturer would the better be able to compete with the foreigner as regards price. At present a large proportion of the chemicals used in photography come from abroad—most of the new developers, for example, and also our old friend pyrogalllic acid. At one time this was almost exclusively made in England. Now—we think we are safe in saying that—none is made here, or, if it is, the quantity is very small indeed. Colours from coal tar were an English invention, and a few large fortunes were made with them, but the trade has almost entirely drifted to the Continent. In the manufacture of some of these alcohol is largely employed, but in some cases methylated spirit cannot be used. Hence it follows that if the British manufacturer has to use duty-paid spirit and the foreigner can get his spirit free of duty the former cannot compete with the latter, however much enterprise he may possess. There is yet another reason why there is so little of the coal tar colour made in Great Britain, which has been due to our patent laws. If, for example, an English inventor patents his invention here, and, say, in Germany, according to the German law the invention must be worked in Germany within a certain period from the date of the patent or it lapses there. But if a German patents his invention here he has no such restriction. He simply obtains his patent, and thus secures a monopoly for the term of the patent and produces the thing in Germany and supplies the English market. Under the Patents Act of 1902 this state of things is modified in a somewhat half-hearted way. Now, a patentee, whether English or foreign, is bound to grant licences to work his invention on proof being given that the reasonable requirements of the public have not, after three years, been satisfied, or the patent may be revoked. So far, so good; but there is little question that the enterprising German will keep the English market well supplied even without the fear of his patent being revoked.

Talking Pictures.

The idea of wedding photography with some kind of talking apparatus, so that the figures seen on a lantern screen could be made more lifelike, is an old one, and some people may be apt to think that it was a natural outcome of the invention of

the cinematograph. In that case it could not be so very old, but, as a matter of fact, the suggestion was made prior to the era of animated photographs, and occurred to the fertile imagination of a Transatlantic reporter when Edison first startled the world with his phonograph. In order that there may be no mistake on this point, we will quote from the notice to which we have called attention which is dated December 22, 1877:—"When it becomes possible, as it doubtless will, to magnify the sound, the voices of such singers as Parepa and Titiens will not die with them, but will remain as long as the metal in which they may be embodied will last. The witness in court will find his own testimony repeated by machine, confronting him in cross-examination; the testator will repeat his last will and testament into the machine, so that it will be reproduced in a way that will leave no question as to his devising capacity or sanity. It is already possible by ingenious optical contrivances, to throw stereoscopic photographs of people on screens in full view of an audience. Add the talking phonograph to counterfeited their voices, and it would be difficult to carry the illusion of real presence much further." (The allusion to the voices of the singers named remaining in "the metal" refers to the circumstance that in the original phonograph the record was made in tinfoil, and not in wax, as it is to-day.) Later on, when the phonograph emerged from the experimental form, and cinematography became possible, we were promised operatic performances by the combined instruments, and, if we remember rightly, Edison or his representatives had a special theatre constructed in which actors and singers went through complete performances, so that sound records and pictures could be made. But the hopes thus aroused were doomed to disappointment, and, so far as we know, these elaborate experiments bore no fruit whatever. We presume that the failure was due to the circumstance that although the phonograph will register with marvellous fidelity the strains of the band of instruments, it will not take up the more tender tones of the human voice unless the singer's mouth is close to the instrument. Since the time of these pioneer efforts to make the cinematograph and phonograph act in concert, there have been many minor attempts to do the same thing. The notion has once more been revived, and an instrument bearing the terrible name of Biophotophon—the invention of which is credited to Herr Oscar Messter, of Berlin, and M. Gaumont, of Paris—was tried the other day at the Fulham Theatre, with a view to test its suitability for a music-hall "turn." In this case the cinematograph is allied to the gramophone, and we may soon expect to see this double-barrelled machine employed at some of the music-halls, and we trust that it will prove more successful than its predecessors. We have heard of one or two carefully-tended phonographs give results which place them on a level with musical instruments, but it must be confessed that the rank and file of these instruments recall to the mind the voices of Punch and Judy rather than anything of a more classical nature. This has hitherto been one of the bars to success in dual performances of the kind referred to.

MESES-GORIS AND FILS' Baryta Papers, sold by Mr. Otto Rosenfield 104-105, Cheapside, E.C. The above firm, which successfully brought on the market their Baryta Papers some time ago, has submitted us now samples of their post-card paper coated with baryta, and owing to the excellent surfacing of both the matt and brilliant paper should be certain of obtaining the same success as their former papers. The firm has given their special attention to this post-card paper, which is supplied in several thicknesses, and which should be of interest to all the photographic paper makers and professional photographers making their own sensitized paper.

GAS BURNERS, AND ELECTRIC LIGHTS.

our gas burners, the flames they give, the gas they consume, the waste or economy that may attend their use, it is not to be said, notwithstanding the virtual universality of coal gas, it can by no means be said that the schoolmaster is abroad, for, if there is one thing more than another about which the English householder, not to speak the photographer, is in a state of crass ignorance, it is the working machinery of the material that supplies him with his daily artificial light. He is, too, in a state of chronic antagonism to the gas companies, all of whom are engaged in a colossal conspiracy to defraud him by charging him for gas he is quite sure never used. It is useless to point out to him that his gas-bills always show the readings of the meters, so that he can check for himself the quantity charged for as shown by the meters. So much the worse for the meters is his reply; he is charged twice as much as last quarter, and he knows quite well he burnt no less gas than more. But he does not avail himself of his legal rights, which entitle him to have his meter tested without charge if it proves to be inaccurate. He takes his illogical stand on the fact that he has to pay the examination should the meter prove to be in correct condition. He prefers to hug his grievance, imaginary as it is, as a rule, and goes on grumbling. In view of the frequent employment of gas as an illuminant for portrait work in the studio, every photographer who has such an installation should be on terms of friendly acquaintance with his gas meter, and thus be able to check waste and calculate the cost of his exposures. To read a gas meter is so ridiculously simple that we will not insult the intelligence of our readers by explaining it; but we do advise them to consult it more frequently than we believe is usually done. The presence of defective burners would be readily indicated by the consumption of gas in proportion to the light obtained, and, in the rare event of a meter actually giving incorrect indications, this fact would most probably reveal itself. It is quite possible, for example, for a No. 6 burner in bad condition to give more light than a No. 5 in proper order, and what that means in the gas-bill is readily understood when it is remembered that the number which is always stamped on a burner, although often invisible through sooty deposits, is taken to represent, very roughly, the number of feet of gas per hour consumed. We know of one establishment where the ordinary fishtail burners are renewed annually as a matter of routine; an old burner does not have the same value as a new one, and the insignificant cost of new burners scarcely interfere with the economy of the arrangement, which also is further largely governed by a judicious attention to the pressure. Undue pressure gives more light at increased cost. Particularly should these things be attended to in the dark room, where a maximum of light and a maximum of products of combustion would naturally be sought. When Welsbach mantles are made use of, the question of pressure is of paramount importance, especially with the older type of burner. If the pressure is at all excessive, it is often possible to more than double the light given by turning the gas down considerably, thus making a gain of over 300 per cent, and having a large number of burners are in use, as in portrait work, by gaslight, what this means to the gas-bill needs no explanation. It is now well-known, though the knowledge is not always put to practical use, that light obtained by Welsbach mantles cost about a third of the sum that would have been paid for the same amount of illumination by the best fishtail burners. In this connection a very bold suggestion was recently made at a meeting of the Manchester and District Junior Gas Association, by Mr. F. A.

Sinnatt. He said gas engineers seemed to forget that there were two ends to the gas-pipe, and they did not pay sufficient attention to the "flame-end." He thought the lights should be superintended by the gas engineer, and he urged that what was wanted was a perfect incandescent mantle, which should last a year with ordinary usage, cost not more than sixpence, and give a high candle-power. A gas of high heating power and low luminosity, costing not over two shillings per thousand could be burned, and he made the further suggestion that every user of gas for illumination should be compelled to use incandescent burners. Possibly before any such consummation is arrived at the use of electricity may have become universal. The initial cost of bringing the current into the premises stands most in the way, as landlords—though they will, where there is an electric installation in the neighbourhood, willingly wire their premises instead of putting in the accustomed gas-piping—will not replace existing gas fittings for electric wiring; and, although, light for light, electricity may be—though we doubt it—dearer than gas, the convenience and the saving of cost of decoration, through the absence of the dust that accompanies the use of gas, more than outweighs any loss. Further, the easy switching on and off of the light from the handily-placed switches lends itself to economy by putting out the light in cases where with gas there would be waste from unnecessary burning. As regards the cost of various illuminators, an interesting set of figures is published by Mr. J. W. Bradley, Engineer to the City of Westminster, and they possess a special interest to photographers who contemplate artificial-light portraiture, as they deal with the more powerful type of lamp, such as probably we used in the studio—that is to say, street lamps. He finds, including all costs—maintenance, interest on capital, sinking fund, etc.—that Sugg's high-pressure lamps in Parliament Street come out at 7.65 pence per year for 1 candle-power. The electric arcs on the Westminster Supply Corporation come next at 8.73 pence. When, however, the average of six tests were taken, this order was reversed, arcs being 8.7 pence, and the incandescent gas 9.85 pence. The triple flat-flame burners in the Strand worked out at 47.5 pence, and the arc lights varied, according to charges of the various companies supplying it, the exact figures being 8.7 pence, 11.5, and 15.1 pence per candle-power for a year. We think we have said enough to show that economy and efficiency will go hand in hand with the use of common-sense in the employment of gas or, indeed, any form of artificial illumination.

THE Royal Photographic Society of Great Britain.—Technical meeting to be held at 66, Russell Square, on Tuesday, April 26, 1904, at 8 p.m. "The Artistic Aspect of Photography," by Mr. F. C. Tilney.

THE Austin-Edwards Monthly Film Negative Competition.—The prize camera for current month has been awarded to Captain H. G. L. Mesurier, R.E., Dean Stadwell House, Weyland, Penn., for his pair of negatives "Crabbed Age and Youth."

WE learn that Messrs. Gold, Smith, and Co., Photographic Mount Manufacturers and Dealers in Photo Requisites, have turned the whole of their premises, 4, Victoria Bridge, Manchester, into stockrooms, and have taken additional premises at 44, Chapel Street, Manchester, which are now opened as offices and showrooms.

A MIRACLE!—Had this happened in the middle ages it would, doubtless, have been regarded as a miracle. Some nights ago the back of a photographer's in Holborn caught fire, and the flames were not extinguished before a great number of valuable prints and paintings had been destroyed. Among the latter was a large and beautiful picture of the "Ecce Homo" type. Searching among a mass of charred fragments of prints and pictures the salvage men discovered that the figure of Christ in this picture was undamaged though everything around it had been burnt to tinder.

JOTTINGS.

"To sit in solemn silence in a dull, dark" Court, watching the dispensation of justice, as was my fate last week, is to me very like becoming for the time being an inhabitant of another world, where the principal occupation of the people is that of daily dancing on the Decalogue. The one point of photographic interest in the long-drawn-out family squabble to which as an uncalled special juror I was compelled to listen in Court III. (King's Bench Division) up till Friday afternoon, was the attempt to prove that the handwriting of an alleged libellous telegram was that of a person prominent in the case who had signed somebody else's name. Enlarged photographs of the "wire", and some letters were made the subjects of expert examination and evidence, and the characteristics of letter formations and peculiarities were minutely discussed by the learned gentlemen engaged in the case. In the end the authorship of the telegram was admitted by somebody quite different to the person suspected. It is extremely awkward when the resources of science are unsuccessfully utilised to prove that Smith did a thing for which Brown was responsible. For the credit of photography a different ending to the case might have been desirable. A breakdown of this kind is apt to make people look with growing suspicion upon evidence that does not lie. By the way, I wonder what offence can be laid to my charge in a previous state of existence that regularly each spring I should be hauled off to the Royal Courts of Justice to contemplate other people's troubles? I would rather be afloat, especially if I were certain that I should be followed on my journey by such remarkable and whole-hearted appreciation as that which seems to be available in Liverpool.

The association of the name of Dibdin with marine matters is quite appropriate. Charles Dibdin wrote sea-songs which are still popular, and will perpetuate his name. The fame of Mr. E. R. Dibdin is perhaps equally as well assured, although he has chosen different means to his namesake to reach the same end. As a marine interviewer he scores a very striking success; I am not for one moment suggesting that either party to the now celebrated interview is talking in a manner suitable for reception by those mysterious warriors known as "Horse Marines." The purely personal part of the interview is amusing, and nothing more, as the following extracts will show. The interview opens in this fashion:—"Glad to go? Well, yes and no," said my unsuspecting victim. "The trip has its attractions, of course; but I am so unaccustomed to running off and leaving the island to take care of itself, that I can't help feeling anxious as to how matters will go on in my absence." E. R. D.: "You will be able to comfort yourself daily by observing with what equanimity the captain goes below and leaves the first officer in charge of the ship." A. H. H.: "True; but he knows he will always be within call if required; I won't. During the eight or nine years I have conducted the 'A. P.' I have never deputed the passing for press for more than a single week's issue, and have prepared almost everything in detail. During all the time I've never allowed myself a complete holiday; even when I go off ruralising, or judging, or photographing, I take the 'A. P.' with me, or, rather, it pursues me by post. Letters, proofs, and all sorts of matters connected with business of the paper reach me daily, and I am still seated on the editorial chair though in a seaside lodging, a North-country hotel, a steamer's saloon, or a fisherman's cottage on the East Coast marshes. I've even corrected proofs and written letters on a Yorkshire moor." E. R. D.: "Well, I'll see what I can do about sending you a few disquieting 'Marconigrams' to cheer your loneliness. However, you must admit that if you have been on the stretch for such a long period, a rest, however unpalatable, will be good for you." A. H. H.: "I suppose I

am doing too much. An American editor recently described me as probably the hardest-worked journalist on this side." E. R. D.: "His reservation is quite characteristically American." A. H. H.: "If he meant photographic journalist, I guess he is about right. I don't suppose anyone knows how much work I actually do. I couldn't do it if my hands were not in it. To judge by my own experience, any amount of the work you love is wholesome. I thrive upon incessant occupation. Sometimes I have a whiff of neuralgia, and always regard it as a danger signal, and make a point, when it is quite cured, of going to bed not later than 2 a.m." E. R. D.: "No doubt they have agreed to wait until you have made your fortune, which, I should think, must be at an early date!" In the first number of the recently founded "London Opinion," that very successful and readable journalist, Mr. T. P. O'Connor, puts in a plea for the personal side of journalistic records; that is to say, he would have even the sober columns of the "Times" enlivened by those agreeable touches of description and detailed reference which you see in sprightly publications of the "M. A. P." and "T. P.'s Weekly" class. Hence perhaps the foregoing extract from Mr. Dibdin's interview will prove of interest to those who have not seen the original paper—the columns of your esteemed contemporary and neighbour the "Amateur Photographer."

Avoiding any comment upon this delicious morsel of journalistic fare, one passes to the reflection that your modern photographic editor is in the majority of cases neglectful of obvious opportunities for publicity which are at his command, and no doubt Mr. Hinton will earn general thanks for pointing out how easily admiration of this kind may be obtained. If Mr. Dibdin's attentions should have the effect of securing his "victim" an offer by the leaders of the New York F. H. Hundred, to be temporarily included in their august company, nobody will be surprised. Other, and what one may term business, parts of this interview as distinct from the extracts that have been quoted, touch some remarks of my own which appeared in this column on March 25, 1904, and must, I suppose, be regarded in some sense as an answer. My complaint on that occasion was that no official systematic attempt appears to have been made to secure a thoroughly representative display of photographs from leading British workers, at the St. Louis Exhibition. The reply to that from Mr. Hinton through Mr. Dibdin, is that "imaginative persons have declared in print that the work was done secretly and suddenly by a committee whose origin was as mysterious as its proceedings." Then follows a long account of the steps taken by the Royal Commission, culminating in the management of the British Photographic Section of the St. Louis Exhibition, placed in purely irresponsible hands. This is not a question of personal fitness or qualification, but one of principle, and the principle that many fellow-members of the Royal Photographic Society also wish to reach is that the whole of the British Photographic Section at the St. Louis should have been directly under the control of the one representative photographic society in this country; the one only representative national photographic society, namely—the Royal. The explanation given as to why this was not done is to satisfy Mr. Hinton, but probably nobody else. There seems to have been a blunder somewhere, and it has not been repaired by paying the Secretary of the Royal Photographic Society the compliment of placing his name on the committee. Mr. Bartlett himself should have been at St. Louis, or, failing him, somebody else should have been officially deputed to represent the Society and do the work of selection, and hanging.

the time has gone by when your heaven-born judge of pictorial photography was an essential factor in exhibition organisation and management. There are in the Royal Photographic Society scores and scores of men quite as competent to undertake the work at St. Louis which Mr. Hinton by comparison finds so very, very arduous. After all said and done, he need not have gone there had he not wished to; and being there, and I hope having a good time, it should, I think be made quite clear that he only represents himself in the matter; but I can dismiss this part of the subject to revert to the main theme of discontent, namely—the mismanagement of the matter by the Royal Commission, which seems to have passed over the Royal Photographic Society in the matter. Much the same sort of mismanagement characterised the photographic section at the Paris Exhibition. There was a small and privately organised pictorial section, illustrating merely one particular school of work. The individual exhibitor had to do the best he could himself, which was a very best indeed. There was a great deal of discontent at the time, that apparently did not have the effect of educating those responsible in the Royal Commission to their very obvious error in the matter.

I hope nobody will think that in dealing with this Dublin review in these pages I am animated by a desire either to get a cheap copy out of it, or am at all jealous or envious of the gentleman who has gone afloat. My path in life lies in a different direction to that of my former adversary, Zolius. Pictorial photography nowadays affords few opportunities for purely controversial treatment. My object chief on this occasion is, whilst regretting that the publication of such childish nonsense should have the effect of throwing ridicule upon the reputation of the one most immediately concerned, it should also be the means of creating a false impression as to the position of the general body of members of the Royal Photographic Society as regards the British demonstration at St. Louis. Some of us have devoted years of effort to make the Royal Photographic Society worthy of its position, and, to say the least of it, it is galling that that Society, instead of being to the fore, actually, officially, and primarily, at St. Louis, should occupy a position in the background. A test was called for, and is hereby made, and after that I think the matter can be dismissed, as it is too late to do anything now. I am making no suggestion of bad faith, but of carelessness, or at any rate carelessness, there undoubtedly was in regard to the position of the Society in the matter. COSMOS.

THREE years ago the Empress of the French, accompanied by her son, Count Primoli, came to the grounds of the Tuileries to see once more the spot on which had stood her Imperial home and the garden in which her little son once played. There is a flower-bed near the gateway, and the Empress, wishing to take away a souvenir of her visit, stooped and plucked a blossom. Count Primoli, an ardent amateur photographer, had his camera with him. He thought it would make a pretty picture, and was about to take a snapshot when a sergent de ville appeared, and, laying his hand on the shoulder of the Empress, arrested her. Count took the snapshot, and still has the picture—the arrest of the Empress for picking a flower from the garden that once her own. When Count Primoli hastened forward and told the policeman who the lady was, the man saluted, and exclaimed, "Take your flower, Madame, and grant me your pardon."—Dagonet The Referee."

A NEW OPTICAL BENCH.

[Translated from Eder's "Jahrbuch für Photographie und Reproduktionstechnik," 1903.]

IN the "Jahrbuch" for 1902, p. 151,* I described a method of determining with exactitude certain errors in lenses and at the same time sketched the outline of an optical bench which would be of use in making such observations. Professor Eder at once instituted experiments according to the proposed method, and, having satisfied himself of its utility, had an optical bench of the kind made, for the Imperial Technical School, by the firm of O. Toepfer and Son, of Potsdam. This apparatus is now ready, and I take this opportunity to give a short description of it. I will give a more complete description of the apparatus, together with a full account of the examination of a lens by its means, in another publication, as soon as a second has been constructed for the Astrophysical Observatory at Potsdam, and brought into use.

A horizontal table, cast in one piece, is supported upon an iron column, the foot of which rests within the circle A (Fig. 1). Upon this table, to the left, is a slide groove 1 metre

Fig. 1.

long, LC, which is projected to the right through the sector, B, comprising an angle of about 120 deg. A strong arm, with two friction rollers, supports the astronomical telescope F, and it is made to turn upon the centre C, within the sector. The arm can be clamped firmly to the sector at one part, by a screw, and its position may be read off the divided circle correctly by a vernier, to three minutes of arc. Single minutes may be estimated. The telescope has an object-glass of 75 m.m. aperture and 90 c.m. focus. It has a draw-piece 40 c.m. long actuated by the pinion T, and its extension may be read to 1 m.m. by the mirror S. By means of a bayonet joint, at the eye-piece, the micrometer O, a dark-slide, or a small spectroscopic slit with a prism of 60 deg. may be attached. These three appliances may be used in two positions differing from each other by 90 deg. For example, the micrometer may be used with the screw in a horizontal or vertical position. In front of the eye-piece is a revolving plate carrying glasses of different colours, and a small train of prisms for direct vision can also be attached. The carriers R for the lens under examination, and M, for the test object, slide on the swallow-tail shaped rail LC. Fig. 2 shows a perpendicular section of

Fig. 2.

* See "British Journal of Photography," February 20, 1903, p. 146.

this portion. The lens-carrier R is of simple construction. It is formed of a strong cast-iron frame into which a square board may be slid at the top. The board is provided with a flange, for holding the lens, the same as on a photographic camera. By means of the screws D, the lens may be centred and fixed. If desired, the simple carrier R may be replaced by a more complicated one, which permits of the lens being turned upon a horizontal axis to test the centring of the several surfaces, and upon a vertical axis to determine the principal points by the well-known swinging method.

The test-holder M consists of two parts sliding on the rail L.C. That shown to the right in Fig. 2 serves as a fixed support for the head of the micrometer screw P, which is actuated by a rod, with universal joint, terminating at the handle G, so that it may be manipulated at the eye-piece. When the right division of the sliding part is clamped to the rail L.C., the left division may be moved micrometrically by turning the screw. The latter carries the swallow-tail shaped rail Q, placed at right angles (Fig. 1), upon which the frame E (Fig. 2) may be moved. The platform H, behind the rail Q, is provided to carry an illuminant. Both rails, Q and L.C., are divided into millimetres, and the position of the sliding parts upon them may be read off accurately to 0.1 m.m. Small differences in the distance between the lens and test object may be accurately measured to 0.001 m.m. with the micrometer screw P, which has a pitch of 1 m.m.

To adjust and test the apparatus, it should be set up so that it is possible to see its full length through the telescope. After removing a check screw, the micrometer O may be swung not only 90 deg., but round an entire circle. The telescope is then sharply focussed upon some distant object, and the wire of the micrometer is moved until it exactly covers some point in the image, whilst the micrometer is revolved. When this adjustment is made, the wire cuts the geometrical axis of the telescope, or, in other words, the optical and geometrical axes coincide. This position of the micrometer screw may be called zero, and the reading on the drum should be noted.

Next the optical axis of the telescope must be made parallel to the runner L.C. The draw of the telescope should be extended until a very distant object is sharply focussed in the plane of the wire. A plate with a circular aperture of about 2 m.m. aperture is placed in the frame R. A similar plate is also placed in the frame E. The carriers M and R are brought as close together as possible, and the plates are shifted till the two apertures coincide. The frame R is brought up to C, and M is moved as far as possible in the direction of L. The line between both apertures should then lie parallel to the runner L.C. If a lamp be placed behind the aperture at E, the ill-defined circle of light visible in the eye-piece O should be halved by the micrometer wire standing at zero. With the micrometer wire upright, the telescope is turned upon the point C until the circle of light is equally divided. This direction of the telescope may be taken as zero, and the corresponding reading upon the sector of the circle B should be noted. When the wire is turned to its horizontal position the circle of light should also be equally divided, but as a rule the mechanism will have ensured this. If a slight correction appears necessary, it may be done by placing tin-foil under one of the supports of the telescope. Lastly, the frames M and R, and especially the transverse runner Q, should stand perpendicular to the optical axis at its position at zero. For this adjustment an accurately worked mirror should be placed in the frame M, for examination of the reflected image of the micrometer wire illuminated by a glass plate, placed at 45 deg. to the optical axis, between eye-piece and eye (Gauss eye-piece). The image should then be covered by the wire, which may be effected by altering the direction of the runner Q. The position of R may be adjusted similarly.

The object glass of the telescope may be examined in the following manner.* About 100 m. from the object-glass stop, with a small circular aperture, is set up. Behind this sodium flame is placed. The telescope is set so that the point of light may be seen in the centre of the field, and the sector B is then clamped. A stop, belonging to the apparatus is then placed in front of the object-glass. This stop has a row of circular holes, measuring 1 to 2 m.m. each, pierced across the diameter, and, as may have been seen from Fig. 3, these holes

Fig. 3.

are arranged symmetrically to the centre of the lens. The draw of the telescope is pushed in, until the images of the holes are seen distinctly separated in the eye-piece. Their position is then measured with the micrometer. If m and m_1 be the readings upon the drum, when two holes, situate symmetrical to the centre, are focussed, and if r be their distance from the centre, the difference may be expressed by $e = m - m_1$. The reading at S, on the draw of the telescope, where the measurement was made, may be denoted by A_1 . After the series of measurements has been made, the draw of the telescope is pulled out beyond the picture plane, where the images of the holes run together, until a point is reached on the other side of the focus, where all the apertures are again separated from each other. The measurements made here, position A_2 of the draw-piece, give the distance e for the same holes. If both quantities e_1 and e_2 be taken as positive, the reading A_0 , when the plane of the micrometer wire coincides with the picture plane, may be calculated by the following formula:—

$$A_0 = A_1 + \frac{e_1}{e_1 + e_2} (A_2 - A_1).$$

By proceeding in the same manner with each other pair of holes, the exact position of the image for the different zones of the object-glass may be ascertained. After this examination has been made for the horizontal diameter of the object-glass, those for the vertical and the two diagonals situate at 45 deg. should be made. In this manner spherical aberration, zone errors, and astigmatism at the centre may be accurately determined for monochromatic sodium light. A similar examination is then made with the draw-piece fully extended and the object at very short distance. In this way the necessary figures are obtained to find the position of the image of an object at infinite distance.

The chromatic aberration of the object-glass is ascertained in the following manner. Behind the stop, placed at a distance, a source of light emitting rays of different known wavelengths is used instead of the sodium flame. A mercury arc lamp is suitable for the purpose, but a good substitute may be found in sufficiently luminous Geissler tubes, or an electric

* The first communication concerning the method of extra focal measurements which I have used since 1899 with much success, even for testing large telescope object glasses, appeared in the "Zeitschrift für Instrumentenkunde" (1900, p. 51).

lamp with Bremer or Siemens carbons, impregnated with metallic salts. If these sources of light, which give line-spectra, are replaced by an ordinary flame giving a continuous spectrum, the chromatic error can only be ascertained by several groups of rays, such as "red," "green," etc. A stop, with only two symmetrically placed apertures near the margin, is then placed in front of the object-glass. If these apertures are on the horizontal diameter of the stop, the direct-vision prism should be placed in front of the eye-piece, so that its refracting edge lies horizontally. With the prism in this position, it will still be possible to sharply focus the wire of the micrometer through prism and eye-piece. If the micrometer is returned to the extra-focal plane at position A, a glance through the eye-piece will at once disclose the nature of the achromatism of the object-glass. Two symmetrically placed spectra, facing each other, are seen in the field of view, each of which is an exact picture of the colour curve of the object-glass. Focussed at A, the spectra of an optically achromatised object-glass have the form of Fig. 4, and if

Fig. 4.

Fig. 5.

focussed at A, the form of Fig. 5. If the sources of light were those mentioned are used, these spectra show their corresponding colours, and in order to ascertain the exact focus for each of the rays, it is only necessary to measure with the micrometer the distance between both spectra at the corresponding position, and from this the value F may be obtained by the formula already given.

When the colour-curve for various zones of the object-glass is thus determined, the chromatic difference of spherical aberration may also be arrived at.

To follow the colour-curve further into the violet and ultra-violet region of the spectrum, the spectrograph is attached to the telescope instead of the micrometer. Two spectrograms are then obtained in precisely the same manner as we have already described, their forms being as in Figs. 4 and 5, and by measuring the position of the foci may be ascertained. Of course an allowance must be made for the difference in the distance between the slit and the micrometer wire, in relation to their juncture with the telescope. This must also be done in the position of the dark-slide, when direct photographs are taken.

The focus of the telescope object-glass, or, to express it more exactly, the distance between its second nodal point and the wire of the micrometer wire, for a given tube extension A, may be ascertained by measuring with the micrometer an object subtending a known angle, as, for instance, a metre measure set up at a definite distance. Or, better, the image of a plate in the dark-slide may be measured accurately. These extra-focal measurements, which have already been described, will also give reliable information as to the focal length, if they are made by setting up the object at widely different distances.

After the apparatus has been adjusted, and the object-glass examined in the manner described, the instrument may be used for testing other objectives. As it would require more space than is at my disposal, I cannot enter into a detailed description of the many applications to which it may be put, but I will make a few short remarks concerning them.

The lens to be examined is placed in the frame R, as shown in Fig. 2. The centring is corrected by observing the reflex image of the stop inserted in the carrier M. The frame R is brought sufficiently close to C to permit of the front surface of the lens standing perpendicularly above the axis C. To facilitate focussing, a short piece of tube is placed on the cap of the telescope, to bridge over the space between the object-glass and C. The aperture of the lens is then brought close up to the end of the tube and the position of the sliding part R is read off the scale. The sliding part is pushed back for removal of the lens cap, and, after uncovering the telescope glass, the part is brought back to the original position. For the reasons given, the telescope is then focussed for infinity and the carrier with the object moved forward until the image of the stop at M can be sharply seen at the eye-piece. The stop is then situated at the focus of the lens under examination.

The tests for spherical and chromatic aberration are made in precisely the same manner as when the telescope object-glass was examined. The sodium flame is placed behind the stop, with small aperture, inserted at M. The stop shown in Fig. 3 is placed in front of the object-glass of the telescope, and the measurements are made for the two extra-focal positions in the telescope. In this way the combined zonal errors of the two lenses are obtained as one, and, as those of the telescope objective are known, those of the lens under examination may be ascertained by the methods described in the "Jahrbuch" for 1892 (see B.J.P., February 20, 1903). The colour curve of the lens may be determined similarly. If it be desired to ascertain generally the achromatic correction of the lens, an ordinary lamp may be placed behind the stop M, instead of using the eye-piece prism, the spectrograph, and the monochromatic source of light. The focus for the different colours may then be ascertained by using the coloured glass stops placed at the eye-piece, as described in the "Jahrbuch" for 1902. To ascertain the position of the astigmatic picture planes, a glass plate with a series of parallel lines (ruled screen) is placed as a test object in the frame M. The telescope is focussed for infinity, and so used for the entire series of measurements, as the micrometer screw P is much more serviceable for finding the exact focus. The telescope is swung on the sector B over intervals of 5 deg., and the frame M is slid on the runner Q to a corresponding extent. After sharply focussing, the measurement is read off the drum of the screw P each time. The ruled screen is used first vertically and then horizontally, and thus the location of both astigmatic planes may be determined. By suitably shortening the extension of the telescope and increasing the distance MR, the aberrations of the lens and the position of the picture planes for infinity may be examined in the same way.

The focus of a lens may be determined in various ways by the instrument. The telescope is focussed for infinity and the 2 m.m. stop is put in the frame M. The diameter of the stop is known to one-thousandth of its value by microscopic measurement. After it has been brought into sharp focus by the screw P, the diameter of the image is measured with the micrometer, the screw of which has a thread of 0.25 m.m. If f be the focus of the lens under examination, F that of the telescope, b the diameter of the stop, and B that of its image, it follows that $f = \frac{F \cdot b}{B}$.

To obtain an exactly defined value, sodium light may again

be used, in which case the value of F should be taken from the data obtained in the preliminary examination.

Instead of the above, a point-shaped stop may be placed exactly at the focus, and the micrometer wire focussed sharply upon the image of the stop in the zero direction of the telescope. The position of the telescope is read off the divided circle B , and that of the frame M , off the millimetre scale of the runner Q . The frame M is then shifted a short distance (about 5 c.m.) sideways and the telescope is swung upon the sector and refocussed sharply upon the stop. If the frame M has been shifted d millimetres and the telescope swung through the angle ϕ , then $f = d \cotg. \phi$.

A third method of determining f is given in the "Jahrbuch" for 1902.

The equation $f = \cotg. \phi$ is also used for determining distortion. If the focus be taken in the manner described for larger values of d and ϕ , we obtain, for example, at a greater distance from the optical axis, the reading ϕ , for the focus of d , and the amount of distortion may be ascertained by the equation $V = d - f \tg \phi$.

The diameter of the effective aperture of the lens and its various stops may be obtained very accurately in the following manner. The 2 m.m. stop is brought into focus in the way we have already described several times. A lamp is placed behind it, and, after the room has been darkened, a photographic plate is placed with its film against the lens. The black circle obtained upon development is exactly the size of the effective aperture of the lens. The angle of view may be measured by placing the lens on the centre C and using the divided circle B . In this way, however, only the extreme angle through which the lens transmits light is ascertained. If it be desired to ascertain the extent of field of useful definition, it should not be done in this way, but deduced preferably from the positions of the astigmatic planes.

The apparatus is not intended to give immediate data concerning those technical properties of a photographic lens which primarily interest the purchaser. These are mostly inexact defined and very elastic conceptions, as for instance, depth of focus, sharpness of image, extent of usefully defined field, etc. They will always be found best by direct trial exposures. The apparatus is intended rather for opticians and scientific institutions that they may obtain quantitative information concerning the fundamental properties of an optical system, such as has hitherto been obtained approximately by calculation. By comparing the results obtained by the apparatus with those of the computation, the optician is provided with a means of testing and perfecting his work.

Dr. J. HARTMANN.

Astrophysical Observatory, Potsdam, April, 1903.

MESSRS. EVANS, SONS, LESCHER, AND WEBB, of 56, Hanover Street, Liverpool, have sent us their illustrated price list of photographic apparatus and materials, etc. It is very complete, and contains nearly everything wanted by the amateur and professional. A copy will be sent to any person upon application.

We have just seen the current issue of the "Birmingham Magazine," edited by W. J. Spurrier. It is a praiseworthy production in every way, well printed on high-class paper, illustrated in lavish style. Special attention appears to have been devoted to the production of the half-tone blocks, and the subjects dealt with, although avowedly of local interest, make very good reading for outsiders. The magazine is worthy of the go-ahead city it represents.

HOOD AND CO., of St. Bride Works, Middlesbrough, have sent us a specimen of their wall sheets, which are being specially prepared for photographers to hang in their places of business in order to show customers different examples of photo engraving. The wall sheets are very high-class productions, printed in various colours on plate paper. A space has been left for the photographer to print his own name, and thus push the sale of half-tone blocks from his own subjects.

RADIUM AND CANCER.

THE Paris correspondent of the "Morning Post" gave on Monday an interesting account of Dr. Jules Rehn's experiments with Radium. He says:—

"Dr. Jules Rehn, of the Pasteur Institute, who is the fortunate possessor of a minute quantity of radium, has supplied me with some interesting particulars of his researches into the influence of this remarkable substance on cancer. His conclusions, so far as they go, are encouraging than those of the London hospital surgeons, who recommend condemned radium as ineffectual in this form of disease. He claims to have completely cured a mild form of external cancer, and to have produced marked effects, amply justifying further investigations, in two internal cancerous growths, one of which was in an advanced stage before the treatment was begun.

"Dr. Rehn operates with ten milligrammes—the sixteen-hundredth part of an ounce—of bromide of radium, enclosed in an ebonite tube resembling the small end of a telescope, with a film of dark brown talc in place of the lens. The talc prevents the passage of only one of three varieties of rays emitted by the radium. The others pass through it as if it were non-existent, and produce identical results on the skin of man and of animals.

"Before proceeding to deal with the effect of these rays on tumours it may prove interesting to note what follows when radium is used on normal skin. Five minutes' application of Dr. Rehn's little box causes absolutely no pain, but twenty-four hours afterwards a red mark marks its appearance, lasts for a fortnight, fades, and ends in a scar resembling that of a burn. If the application be continued for ten minutes instead of five the mark becomes visible in eighteen hours. In neither case does there any pain or ulceration. The latter phase does not occur unless radium has been applied for at least an hour. If the spot thus caused is treated medically suppuration may be prevented and the wound cured in six weeks or two months. If uncared for it gathers, becomes painful, and lasts an indefinite period not yet ascertained. Some of these wounds or burns caused three months ago by an hour's application of radium still show no signs of healing. Moles can be destroyed by applying radium for ten minutes.

"CASES TREATED WITH RADIUM.

"We now come to the first instance of the effects of radium on cancer. The case was one of the mild variety known as papillary epithelioma and the seat of the growth was in the corner of the eye. The radium was kept for half an hour on each of several different points of the cancer. Ulceration appeared on the tenth day, cicatrization on the twentieth, and the result was a complete cure. In passing it may be remarked that the substance was tried for an hour on the eye of a blind patient, but failed to revive the atrophied nerves. The inference were it allowable to draw conclusions from one experiment, is that radium is not likely to restore sight to the blind.

"A cancerous ganglion in another patient's neck was subjected to radium rays half an hour a day for fifteen days. When the ganglion was afterwards removed, it was found that the cancerous tissue inside the capsule had undergone complete decomposition. The corresponding ganglion on the other side of the neck, which had not been treated with radium, presented the ordinary characteristics.

"The worst case treated was one of cancer in both groins. A surgical operation had been performed last August, but it was impossible to remove the whole of the growth, and the patient's death was therefore only a question of time. The effect of radium was to stop the development of a shoot which had made its appearance under the skin on one side. The cancer on the other groin was very large, but its extension has been prevented by frequent applications of radium, lasting for half an hour to an hour, and effected by the patient himself without assistance from doctor or nurse. Cancerous tissue is still present, but in a condition of the patient—who, but for radium, would now be in a grave—is stationary.

"ADVANTAGES OF THE METAL.

"Dr. Rehn is about to treat a cancer in the stomach with radium through the skin, the great penetrative power of the rays being quite sufficient, he considers, to justify the experiment.

"The effects of radium rays on the tissues of the body are similar to those of the X or Röntgen rays, but the metal has the great advantage of being extremely easy to use, whereas the Röntgen rays require considerably in intensity and require skilled manipulation. Radium moreover, never wears out, and can be applied by the patient.

"To sum up, Dr. Rehn's experiments show that radium does produce curative effects on cancer, even internal, and may prove to be a valuable remedy when these effects have been thoroughly observed and investigated."

ABOUT "INFINITY FOCUS."

is frequently useful to know the distance at and beyond which all objects will be in focus when using a lens of own focal length and a given stop. To obtain the requisite information most photographers have recourse to the published tables—if they are at hand—but the writer suggests a simpler method which he worked out, and has now used successfully for some years. It consists in marking each lens with its "constant," which only requires to be divided by the

The following is a list of constants calculated for a confusion disc of 1-100 in. :—

Equivalent focus of lens in inches.	K.	Equivalent focus of lens in inches.	K.
3	75	6.5	352
3.5	102	7.0	408
4.0	133	7.5	469
4.5	168	8.0	533
5.0	208	8.5	602
5.5	252	9.0	675
6.0	300	10.0	833

number of the stop to give the so-called infinity focus or distance beyond which all objects will be in focus.

The constant of any lens is obtained thus :—

Let f_a = focal aperture or stop,

F = equivalent focus of lens, in inches,

K = required constant ;

Then :— $\frac{F^2 \times 100}{f_a \times 12}$ or $\frac{K}{f_a} =$ infinity focus in feet,

and $K = F^2 \times 8.33$.

Example :—

Required, constant and infinity focus of 6 in. lens at f_6 .

$K = F^2 \times 8.33 = (6 \times 6 \times 8.33) 299.8$ (say 300).

Infinity focus = $\frac{K}{f_a} = \frac{300}{6} = 50$ ft.

The infinity foci for other stops will be :—

Stops f_6 f_8 $f_{11.3}$ f_{16} $f_{22.6}$ f_{32} f_{45}

Infinity given in feet 50 37.5 26.5 18.7 13.3 9.3 6.6

Graphic curve of constants.

E. T. RUTHVEN-MURRAY, M.I.M.E., M.I.E.E.

ON THE HISTORY AND LIGHTING OF THE MAGIC LANTERN.

[A paper read before the Royal Photographic Society.]

I do not intend to deal so much with the question of the illuminants of lanterns of the present day, as with some of the more obsolete methods of illumination. There is no doubt that the first conception of the magic lantern was by one Kircher, a Jesuit priest, who lived nearly two hundred and fifty years ago. He discovered a method of producing strange effects by means of shadows, an idea which was largely carried out in the older forms of the optical lantern. In 1802, a Frenchman, named Phillips, astonished people of London with what was known as the phantasmagoria lantern. M. Phillips held the lantern under his arm, making the pictures larger and smaller, according to the distance from the sheet. There is a description of the performance in "Chambers' Journal" of April 28, 1849, and an amusing description of the phantasmagoria lantern also appeared in a catalogue published in 1848 or 1850, by Carpenter and Wesley. The Argand Pot lamp, invented in 1769, supplied air in large quantities to the interior as well as to the exterior of the ring of flame, creating a fierce draught by means of a chimney, and causing the combustion of the unconsumed carbon which otherwise would have escaped into the air. This was improved upon by placing a brass cone over the flame. The lamp was filled with a thick oil, tallow, or lard, and a circular wick, similar to that used in the Argand lamp, or a rough piece of cotton, was employed. The tallow or fat had, of course, to be made hot before one could use the lamp. There was a hole in the centre by which a draught was created to supply the oxygen, and the lamp was about the same size and shape as a lime tin. This lamp was modified, I believe, by Mr. Frederic Newton in 1851, when that known as the Fountain Argand Lamp was produced. In this lamp, the glass chimney was contracted about an inch above the flame in order to increase the light, but this gave way to the brass cone, as used in the old Argand lamp. The contraction of the glass chimney caused a similar contraction of the flame, and gave in consequence a whiter light. This lamp did duty from, he believed, 1851 to about 1874; its light was white and gave no trouble; the supply of oil was conducted from a cistern by a piece of wire, reaching to the bottom, fresh oil being supplied until it was exhausted. Then followed the lamp of Mr. Marcey, of Philadelphia, called the Sciopticcon, which was introduced into England by the late Walter Woodbury. This lamp gave a very white light, the combustion chamber being part of the lantern, which was a disadvantage. This lamp has lasted until the present day, and is the groundwork of all the petroleum lamps. Mr. Marcey used petroleum and two parallel wicks, the hood being part of the lantern. The heat was intense, and some difficulty was experienced owing to the smallness of the combustion chamber. Two small pieces of glass which came in front were used to produce perfect combustion. The rear one, however, was liable to get broken, and there was some difficulty in replacing it. These difficulties were overcome when Mr. Newton, in 1876, introduced a separate lamp of the same character, with two wicks. This was quickly followed by the three-wick Refulgent lamp, which enjoyed much favour. When three wicks were put into the lamp, the heat of course was increased enormously, and with it the difficulty of the breaking of the glasses. All sorts of expedients were tried in order to overcome this difficulty; by annealing the glass, or making holes in the top of the hood to let the hot air out. They could not for a long time, prevent the glass from breaking. There was an enormous draught when the chimney was put on, and this drew up the flames so that small jets of vapour came out and played on the glass, causing it to crack. Nevertheless, this lamp did duty for a number of years. The lamp had a glass at one end, and the other end

of the hood was closed with a metal reflector. The next lamp that was placed upon the market was one which entirely obviated the breaking of the glass. It was found that a piece of sheet glass bent on a hot cylinder would no longer break whatever the heat to which it might be subjected. The reflector was also put outside, so that it could not be burnt. The lamp had four wicks and, to make the combustion complete, a long chimney. But the greater the flame, the more heat there was; and the larger the wicks, the greater the draught, as was necessary to create a good draught or the combustion would not be complete, nor would the light be good. Five wicks were experimented with, but the result was only an increase of heat with no corresponding advantage.

The lamp invented by Stocks was small, convenient, and nicely made. The question of combustion was carefully studied in order that a maximum amount of light could be obtained with a minimum amount of heat. The ordinary amateur lanternist would not go far wrong with a lamp having fixed quantities, but with an instrument or lamp like this, in which the height of the chimney and wicks have to be carefully regulated, he will surely make mistakes. The chimney is in three parts, one with a rack and fine adjustment for getting the maximum light. When lighting a lamp of this kind, it will be found that the more the chimneys are raised, the thinner and whiter the flame becomes, while there will be reduced liability to getting "shadows" due to the flame being whiter than the other part of the disc. One other matter concerning oil lanterns is important, namely, the cotton that is used. The lamp is often simply filled with oil, without thought of the displacement of the cotton, and then we wonder why the light is not good. Cotton for ordinary oil lamps, and also for petroleum lamps, should be perfectly dry, and should fit the holder properly, with no space to spare. Cotton for oil lamps should be soft and loosely woven; but for paraffin lamps the wick should be closer. Since 1876, very little advance has been made in regard to the lighting of lamps.

I do not propose to say much about the modern incandescent gas lighting, nor do I intend to speak at length about acetylene. The incandescent gas light is convenient for people who have a gas supply in their houses, and who do not care for the bother of an oil lamp. The light of an incandescent mantle is not, however, so good as that of a proper lamp. Acetylene has come into considerable use; it is very convenient, simple, and cheap. The only objection I have to acetylene is on account of its smell, but this can be overcome with care. Generator should be made so that the action of the water on the carbide can be stopped at will; with some patterns, one must exhaust the whole charge of carbide, before the generation of gas can be stopped. I now come to lime-light. I have been trying to collect examples of the earlier methods of lighting by lime light, and believe I have before me a fairly representative series. Professor Robert Hare invented the oxy-hydrogen blow-pipe in 1801. A description of this blow-pipe appeared in the "Philosophical Magazine," 1802, Vol. IV., under the title "On the Supply and the Application of the Blow-pipe." Professor Hare explained that the hydrogen should be first turned on, and the oxygen turned on afterwards. He pointed out that the flame thus obtained was smaller than that of a candle, and proceeded to speak of the intense light emitted when the flame was brought to bear upon certain refractory substances. Here, then, we have described nearly as good an oxy-hydrogen jet as we can get at the present day. As a chemist, Hare tried more particularly to fuse refractory substances by his blow-pipe, than to make use of the intense light obtained; but it is apparent that he produced what is known as the lime-light. Lime and magnesia are extremely difficult to fuse, not because they are the most refractory substances in nature, but because of the difficulty of preventing

from being blown on one side of the flame. Sir Humphry Davy was the first, I believe, to apply the blow-pipe to the lime, and he recommended its application for distant signalling. I have here an early form of blow-pipe without an inter-mixing chamber. I do not think that any particular improvements have been made in regard to the blow-pipe, up to the present time, except in the matter of adjustment. It is hardly necessary to say that when mixed the two gases give a much more intense light. In 1826 Lieutenant Drummond invented a method of signalling by means of the lamp. In this lamp there is a flame of spirit, over which was suspended on a platinum wire a small ball of lime. A jet of oxygen was brought up through the spirit flame to the lime. In the Argand Fountain lamp the jet of oxygen passes up through the wick-holder to the centre of the flame. The ball of lime is suspended over the flame about $\frac{1}{2}$ diameter, for it is necessary to envelope the oxygen, in order to make it incandescent. This lamp, you will see, gives a remarkably fine light. It was a lamp of this kind—the Fountain Argand, with oil and lime ball—which Canon Beechey used, fifty years ago, for his trioptic lantern, because the light could be gathered from the three sides, for the whole of the ball was bright, not as in the case of the cylinder. The images in Canon Beechey's lantern were projected from the three fronts and made to register on the screen by means of prisms. There is a great difference in the qualities of lime. The best limes come from the kilns of Nottingham. Artificial limes have been made, but they do not give nearly so much light.

We now come to a device which has gone quite out of fashion, namely, the rotation of the lime by means of clockwork. The rotation of the lime seems a great advantage, because one may turn the clockwork and turn on the gas, and the lamp will not require attention as does one in which the lime has to be turned by hand. Some early types of the oxy-hydrogen lamps with clockwork attachment are before you. Another method of lighting is that known as the oxy-calcium light. In the original form there was a methylated spirit-lamp, with a piece of wick in the front, and a blow-pipe, attached to its side, which blew through the flame. It was at first necessary to keep the lantern level, or the spirit would not flow, but this difficulty has been obviated in the lamp on the table, which allows the projected image to be raised by tilting the lantern without disturbing the level of the spirit-holder. Other interesting specimens of lamps are shown on the table, relics of the days when the lanternist was obliged to carry with him, his own gas-bag, and pressure board, and many amusing stories could be told of the difficulties of lantern lecturing some twenty years ago. As regards mixed gas jets, in 1832, Mr. J. Hemmings, who lived at Camden Town, brought to the notice of the Society of Arts a jet which he called the Safety Chamber. Previously all the jets had been made without a safety chamber. In this jet there is a long tube packed with brass wire, 1-120th of an inch in diameter. The pieces of wire are about four thousand in number, and are driven in very tightly, to prevent the gas from firing back. Firing back with the mixed jets was a frequent occurrence, particularly when bags were used, and firing back occasionally occurs in the present time. This is due to unequal pressure on the gas burner. An excess of hydrogen be maintained there will be no trouble in this direction, but if there be an excess of oxygen and a minimum of hydrogen firing back may occur. The wire packing in Hemmings's jet had the effect of resisting the flame if it endeavoured to run back, causing it to go out. This jet was in use for a considerable time, until, in fact, the makers omitted to squeeze the wires sufficiently tightly, and then the jet got a bad repute. The chamber was next packed with gauze, and I have seen, again and again, the whole of the gauze give way, owing to firing back due to the slackening of the pressure

on the hydrogen, with the consequence that the whole thing was melted. Then there was invented a safety valve which was supposed to close up immediately the pressure was taken off, but this again seems to have disappeared. The ordinary method of packing jets at the present time is by means of a series of perforated plates. The object of the packing is that the two gases shall be perfectly mixed before they leave the jet. The perforated discs which effect the mixing of the gases are separated by metal rings and are contained in a small chamber which is completely filled by them. The two pipes through which the oxygen and the hydrogen come, meet in this mixing chamber, and the gases passing through the holes in the plates become perfectly mixed. If perfectly mixed, the gases, when lit, give a steady and quiet flame. One of the secrets of jet making is that there shall be no resistance to the passing of the gas, for which purpose the interior of the nozzle is very finely finished. I now show a jet having an adaptation suggested by one of the members of this Society, Mr. Andrew Pringle. It is a jet from which, I believe, one can get as much light as it is possible to get. It has what is known as the "Pringle" cut-off. Having adjusted the lamp, for, say, photomicrography, or an ordinary lantern demonstration, one has only to come back and turn up the light to find it correctly adjusted. In the case of photomicrography, after an exposure has been given one can go away and come back after a time, turn up the gas, and find exactly the same quality of light as before. There is also the blow-through jet, which is so well known that I need not refer to it beyond pointing to some examples upon the table. I have also a few jets, showing methods of turning the lime. In the case of the old blow-through jets, one had to open the lantern for this purpose, sometimes every few minutes. Some people like the flat form of lime, but I prefer the cylindrical form, because it allows a fresh surface of lime to be brought in contact with the gas.

There is a great difference, as I have said, in the qualities of lime, but for the oxy-calcium or the blow-through lamps I do not think anything is so good as the ordinary soft lime. For the mixed gas lamps, however, it is necessary to have the hard variety. Some time ago a preparation of zirconia was put upon the market as a substitute for lime. The makers expected it to overcome the difficulty of the breaking of the lime, but it flaked and discoloured. It had the advantage, however, that, when broken up, it could be pounded and used again. It was not affected by the atmosphere, however, would last a long time, and was handy for some kinds of work.

The optical lantern has stood for over a hundred years and shows no signs of losing its popularity. Considering the extent of science teaching by means of the lantern I think we shall soon find the term "magic lantern" connected only with lanterns bought for children in toy shops.

T. E. FRESHWATER, F.R.M.S.

FORTHCOMING EXHIBITIONS.

May 24.—Bristol Eisteddfod. Photographic Section. Hon. Secretary, Arthur B. Cleaves, Westbury-on-Trym, Bristol.

May 11-18.—Plymouth Photographic Society. Hon. Secretary, Wilfred Grist, 105, Old Town Street, Plymouth.

May 16-28.—Photographic Society of Ireland. Hon. Secretary, E. Webb-Smith, care of Royal Dublin Society, Kildare Street, Dublin.

May 24-28.—Devonport Camera Club. Hon. Secretary, A. J. Catford, 78, Charlotte Street, Devonport.

June-October.—Glasgow Photographic Exhibition. Secretary, Art Gallery and Museum, Kelvingrove, Glasgow.

November 23-25.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

Exhibitions.

CROYDON CAMERA CLUB. SEVENTH ANNUAL EXHIBITION.

THIS Exhibition, held in the Art Galleries, 16, Park Lane, Croydon, from 6th to 13th April, has proved as successful as its predecessors, and a good show of work was on view. The exhibits numbered 322, and included work by many well-known photographers. Demonstrations, recitals, and lantern shows were given every evening during the run of the Exhibition, and in addition to the competitive exhibits a collection of pictures, kindly lent by Dr. C. F. Grindrod, and a trade display by the Autotype Company, added interest to the show. The judges—Messrs. Fredk. H. Evans and Fredk. Hollyer and Rev. F. C. Lambert—made the following awards:—

Members' Work.—Section A (any subject): Silver plaque, W. H. Rogers; bronze plaque, Fred. W. Hicks. Section B (any subject, open to members who had not gained an award at any of the Club's annual exhibitions): Bronze plaque, C. Drew, C. H. Austin, and C. H. Austin. Section C (lantern slides): Bronze plaque, H. P. C. Harpur. Open Classes.—Section D (any subject): Silver-gilt plaque, H. Burkinshaw; silver plaque, D. W. Filshil; bronze plaque, A. Bedding, F. J. Mortimer, and H. P. C. Harpur. Section E (lantern slides): Bronze plaque, F. G. Tryhorn, F. J. Mortimer, and Dr. Geo. H. Rodman.

WEST SURREY PHOTOGRAPHIC SOCIETY.

THE West Surrey Photographic Society held its eighteenth annual exhibition at the Railway Hotel, Battersea Rise, on the 13th, 14th, 15th, and 16th inst. Although the meeting-room of the Society, where the exhibition is held, does not possess the best of accommodation for the holding of an exhibition, even one which is small in the number of exhibits, the Society always compensates for its disabilities by providing a collection of pictures which is worth a careful inspection. This year's exhibition was no exception, and although the pictures as a whole did not show any marked improvement over those which occupied their place last year, the standard was at any rate maintained. A picture by W. T. Marriott, which received one of the awards for its pictorial qualities, was particularly interesting from the fact that it was an enlargement from a negative taken with a pinhole. Of course, such are not rare, but it was another example of the pleasing kind of softness of definition to be obtained in this way. Several winter pictures of the London streets by A. Lockett were noticeable for the good rendering of the effect of mist, but the working on the prints in some was rather too palpable. F. G. Tryhorn seemed to have put his best efforts into architecture, and his cathedral interiors were all examples of careful work, and it was for the "Cloisters, Salisbury," that he received an award. "North Aisle, Peterborough," was perhaps the best of W. G. Rowse's architectural studies, but he had an effective landscape in "The Creek." "A Reedy Stream," by F. Cooper, had some good points, but he had not quite made the best of a good subject. R. H. Bartlett's "Tacking" possessed considerable pictorial quality, and among his other exhibits a large proportion were of more than average merit. "Across the Heath," by Chas. A. Clear, which was adjudged the best picture in the exhibition, was constructed upon the most simple lines, and was independent of any particular features of the subject for the pictorial qualities it undoubtedly possessed. "Nature's Mirror," by V. Serin, a decorative composition of tree trunks and their reflections, had unfortunately placed lights, otherwise it was very original and impressive. Two studies of Florentine architecture, by Dr. Pelham Webb, were characterised by extreme delicacy, and pleasing on that account, though not without minor defects. Mrs. W. H. Goy shewed some rather ambitious attempts in portraiture, and these, with a few pictures of children by J. T. Price, constituted the Society's efforts in this branch of photography. The exhibition was open free to the public, and was well attended. The award took the form of a plaque, which had been specially designed. The judges were Messrs. Alexander Mackie and William Rawlings. Awards:—

Members who have not received an award for three years.—Silver plaque, for best picture in Exhibition, Chas. A. Clear, for "Across the Heath"; bronze plaques, Dr. Pelham Webb, for Staircase in the Bargello, Florence, V. Serin, for "Reflections." Members who have received an award during the past three years.—Bronze plaques: W. T. Marriott, for "Flocks of Sunshine"; F. G. Tryhorn, for "The Cloisters, Salisbury."

REPRODUCTION OF MEDALS AND OTHER BAS-RELIEFS.

THE most faithful way is, strictly speaking, to photograph the medal etc., as it stands, in its bright, bare state; but in order to realise the little of the design and inscription is at its best from any one position of view, take your medal, or as a substitute a new coin of the realm, hold it quite still, and look at it, closing one eye. One instinctive shift of the position of such bas-reliefs upon bright metal so as to bring the position successively into the best angle of view for the different portions. Unless the medals under treatment can be dealt with in some way to remove their mirror-like surface, a quite false effect is the outcome, giving blackness where we expected brilliance, and white marks where dark tool-cuts should be seen.

Commercial requirements demand something more than fidelity to effect in a given position—not an untruth, but, shall we say, a little glorification of facts. The metallic glitter of a medal preserved in its condition means a few fine flashing points, but a large area of exaggerated blackness, which is always a source of disappointment to him who first essays to photograph burnished metallic articles.

The customary method of reproducing medals is to obtain a plaster matrix from the medal and a further plaster cast from this—or to obtain the second cast, working only from the matrix without reversal of the negative. Either of these methods is good as to results, but the appointment of a person delicate-fingered enough to deal satisfactorily with the moulding means perhaps inconvenience to workshop routine and undue consumption of time.

Treatment of the metallic surface by the fuming or sublimation method here described involves so little extra either in time or material that a couple of shillings or so beyond ordinary block prices means liberal profit for such work.

Again, medal-winners seldom like their hard-won trophies to be sent out of their town to strange firms for reproduction. Here lies the advantage of the present method; the local photographer can fume the medal or medals, copying and reproducing these in the form of silver prints which may be sent away to the engraver at much less risk.

The process is brevity itself. The medal to be treated is glued at its unwanted side, and a tab of tough thick manilla is attached, and in turn glued to an eight-sheet board. This is placed under a weight for any convenient length of time beyond a quarter of an hour, to ensure firm adhesion. Then a strip of magnesium about four inches long is burnt close beneath the inverted medal. That is all. The result is a surface of delicate grey with the tiniest relief and detail showing magnificently. Stick the supporting card to the copyboard with two drawing pins and let the operator fire away, treating the coat of medals as though they were platinotypes as to time of exposure. Obviously, to show the relief to good advantage, a strong acute-angle side light is necessary, the darker side being devoid of reflector. This fuming method, by the way, does no injury to the medals, the clinging oxide of magnesia being perfectly innocuous to gold, silver, and bronze. It is removed by the gentle application of a jeweller's brush, an old and soft tooth-brush serving as an excellent substitute.

HAROLD HOOD.

BIRMINGHAM AND THE ELECTRIC LIGHT.

(The article referred to by Mr. Spurrier in his letter.)

THE "forward" part played by Birmingham in the perfecting of the electric light is so little understood, that we think it to be of more than usual interest at this juncture to place the facts on record and in due sequence.

The invention of the "incandescent electric lamp" is generally supposed to be of such recent date that few would age it at even twenty years; but it was clearly indicated as far back as 1836, when both in 1841 and 1845 patents were obtained for incandescent lamps. It is in the last we are interested, for the inventor, Mr. Starr, after finding it too costly to get electricity chemically from a voltaic battery for his lamp, was driven to the conclusion that for practical illumination electric machinery driven by power must be used. Mr. Starr designed a dynamo and came to Birmingham to get it made as the first dynamo was made in Birmingham in 1844 under Worrich's patent of 1842. Mr. Starr also perfected a magnetic "regulator" for arc lamps such as has been re-invented and is now in general use, and in Birmingham, in conjunction with a Mr. Peabody, made

other incandescent lamp. Overwork brought about Starr's untimely death in 1846, aged twenty-five.

Starr's lamp passed into the possession of Mr. Mattieu Williams, co-worker (who died in 1899), who showed it in action in the Town Hall here and many times to his pupils at the Birmingham and Midland Institute.

Councillor R. F. Martineau, who has taken great interest in electric lighting, remembers seeing the lecture experiment just referred to, and later on we are able to give his impressions upon seeing the first electrical lighting-up of the Town Hall.

Not only does the honour belong to Birmingham of being the home of electro-plating, but also of the practical obtaining of electricity from magnetism—inventions which have already revolutionised many industries and much of the work of the world.

For thirty years little progress was made in electric lighting, and even not with the incandescent lamp, which seems to have been lost sight of, mainly from the difficulties in the way. However, in 1847 Mr. J. W. Swan, of Newcastle, attended a lecture at Sunderland where an incandescent lamp was shown, and thus interested he took the subject, but the necessary objects and processes had to be invented. In 1860 he made an incandescent lamp with a carbon rod, but still there was not the electricity to light it.

But progress was being made: Professor Crookes (an Englishman) invented his vacuum tubes, which later on were the means of discovering the wonderful X-rays, and Sprengel his air pump, and, most important, dynamos were made sufficiently effective. So Mr. Swan again commenced, in 1877, his experiments for the production of an incandescent lamp with a carbon filament, he having become convinced that metal (with which other inventors were at work) was not suitable. Mr. Swan made the acquaintance of Mr. Stearn, of Liverpool, a scientific amateur who had acquired great expertness in working Sprengel air pump, and the latter engaged the services of Mr. Watson, now well-known here for his lectures on these subjects at the Birmingham Technical School, who had much to do with signing the apparatus for making the lamps. With this combination of experts and apparatus, Mr. Swan was able in 1878 to make a successful experimental lamp.

About this time Mr. Edison, who was at work on electrical inventions, including lighting, directed his attention to these experiments, and went with his usual indefatigable energy and produced a workable carbon filament. To him is due the credit of making known and putting the electric light upon a commercial footing.

But the difficulties of the carbon filaments were overcome by Mr. Swan, 1878-9, who made them from cotton thread, Mr. Edison's bamboo carbons not being so successful. In 1883 Mr. Swan discovered an ingenious chemical process for preparing the carbon filaments from a cotton, i.e., cellulose or anyloid, which is a fluid made by treating cotton wool with acids.

To carbonise the cellulose is an operation of the most extreme delicacy, and upon its perfection, as of the vacuum, the life of the lamp depends.

Still, without the dynamo (which was first made in Birmingham) the lamps would be useless. The Woolrich machine, of which we give a photograph, was made in 1844, by Messrs. T. Prime and Son (Mr. Prime was mayor in 1869), for electro deposition at their magnetoelectric works in Northwood Street, which it did for many years, until superseded by one of modern type, when they presented the original to the Corporation, and it is now in Aston Hall. It was constructed on the principle of Faraday's great discovery of induction, and when the late professor visited Birmingham he went to see it, and expressed his intense delight at seeing so early and practical use of his discovery. Then—the current was obtained from permanent magnets, but now from electrically induced ones. This original machine was loaned by the Corporation to the World's Fair at Chicago, 1893, where it was awarded the official ribbon, etc. Messrs. Elkington (see vol. I. page 24) also had an early dynamo; it had a number of magnets arranged on a circular frame, and was in use in their plating works from 1848 to 1860. An illustration of it will be found in *Thompson's Chemistry*.

The first use of the electric light in Birmingham was upon September 30, 1878, when Fred Maccabe had an arc lamp as an unique novelty at the entrance to Curzon Hall. On October 28, a football match was played at night at the Lower Grounds, Aston, the kick-off being placed at 7 p.m.

New Apparatus, &c.

The "Night Hawk" Perfect Rapid Bromide Printer (Regd.), made by H. Jenkins, Pier Terrace, Lowestoft.

This piece of apparatus, which has been designed primarily to facilitate the production of a series of prints from one negative, appears to carry out in a practical manner all that its maker claims for it. In construction it is a light box, 14 in. by 18 in. by 18 in., with two interior electric glow lamps, which can be connected with any convenient source of electric supply. One of the lamps is positioned behind a red glass panel, and serves the purpose of a ruby lamp for developing, and a safe light for enabling the paper to be correctly placed for exposure. The other, which is fixed by a thumb-screw to a rod with a universal movement, is the exposing light, and can be fixed at any convenient point to suit the character of the negative. This light can be switched on for any period to make the exposures, while the bromide paper is in contact with the negative, and long strips of sensitive paper can be rapidly drawn across the film side of the negative, with recurring pauses of a few seconds while the exposure is being effected. The printer is particularly useful for rapid post-card printing—as many as 400 per hour having been exposed with it. It takes negatives from 12 by 10 to stamp size, and will do all contact bromide printing, including vignetting. The price, including electric lamps, carriers, masks, fittings, etc., is not great, and we understand that Messrs. Marion and Co., 22, Soho Square, London, have taken up the sole agency.

New Book.

"Dictionnaire de Chimie Photographique." By G. and Ad. Braun fils. Librairie Gauthier-Villars, Quai des Grands-Augustins, 55, Paris.

This work is in course of publication in eight parts of about seventy pages each, and may be subscribed for at a fixed price, or the parts may be bought separately at an increased rate. The important operations in photography are described as well as the chemical reactions. Each substance or compound has its formula noted, and its properties and uses are given. One of the principal features of the work is the excellent description of the more important photographic processes, and for this reason it should be of great use to the amateur, if not the professional, photographer. We are particularly impressed with the clearness and precision of expression of the authors. These qualities are of great value in a work of reference. We translate one of the small references to give our readers an idea of the book:—

Hyposulphite of ammonium ($(\text{AzH}_4)_2\text{S}_2\text{O}_3$, (Thiosulphate of ammonium.)

Chemistry.—Deliquescent crystals of very large size and sulphurous odour, obtained when hyposulphite of barium is treated with carbonate or sulphate of ammonium. Hyposulphite of ammonium is very soluble in water, and insoluble in alcohol.

Photography.—This salt would be preferable to hyposulphite of soda for certain photographic purposes, if the price did not exceed that of the latter, as it has the property of being removable by washing with more ease and rapidly than hyposulphite of soda. It has often been recommended in 20 per cent. solution for fixing dry-plates, and it may be used in the preparation of numerous combined baths for toning and fixing.

"THE Photo Miniature" for this month deals in its typical exhaustive manner with "Who Discovered Photography." After a clear run of sixty consecutively comprehensive numbers, each of undeniable practical value, it completes its fifth volume on this side track, but with the encouraging announcement of improvements and an additional 16 pp. per number for the next volume.

THE "Imperial Handbook for 1904" is to hand, and well sustains the character of its predecessors. In addition to the usual collection of useful formulae, etc., articles on "How Plates are Made," "How to Gauge Exposures in Enlarging," "Gaslight Printing," and "The Use of Stops and how to Focus" add to its attractiveness. A postcard to the Imperial Dry Plate Co., Ltd., Cricklewood, will secure a copy.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
22.....	West London Photo. Society...	<i>Platinum Printing.</i> Mr. E. Walker.
22.....	Watford Photographic Union	<i>A Trip to the Pyrenees.</i> Dr. C. H. Hall.
23.....	Aberdeen Photographic Assoc.	Business Meeting.
25.....	Oxford Camera Club	<i>The Delhi Durbar and a Short Tour in India.</i> The Misses Aitchison.
26.....	Southampton Camera Club	Lantern Slide Competition.
26.....	Camera Club	<i>In a Kewish Hop-garden.</i> Mr. S. W. E. Schriwell.
26.....	Glasgow & W. of Scotland P.A.	Annual Lecturette Competition.
26.....	Nottin'gham Camera Club	Slide Criticism.
26.....	Glasgow Southern Photo. Assoc.	Third Annual General Meeting.
26.....	Craydon Nat. Hist. and Sc. Soc.	Microscopical.
26.....	Birmingham Photo. Society	<i>The Multiple Gum-Bichromate Process.</i> Demonstrated. Mr. Jas. Gale.
27.....	North Middlesex Photo. Soc.	<i>Motifing Gradation in Bromide Prints.</i> Mr. J. Sterry.
27.....	Woolwich Photo. Society	<i>Bromide Paper.</i> Mr. C. Churchill, F.R.P.S.
28.....	Bath Y.M.C.A. Camera Club	Annual Exhibition.
28.....	Richmond Camera Club	Print Competition.
28.....	Liverpool Amateur Photo. Assn.	<i>The Scottish Borderlands.</i> Mr. H. R. Oakley.
28.....	London & Prov. Photo. Assn.	<i>Some Experiments with Tricolour Filters.</i> Mr. A. G. Bull.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION (LIVERPOOL BRANCH).

APRIL 8.—Mr. G. Watmough Webster in the chair. The Chairman proposed that a hearty vote of thanks be tendered to the late Honorary Secretary, Mr. A. F. Mowll, for his past services. The work of organising this local branch had been undertaken chiefly by Mr. Mowll, who had called them together and enabled them to spend many hours to their mutual advantage and in pleasant companionship. Their meeting together, and exchanging ideas and experiences, had been useful to them all, and he hoped, in some measure, to the profession generally. Co-operation was no less healthful in this than in other businesses and professions. There was more work attached to the formation of such a society as theirs than many were aware of, and this had been willingly and capably undertaken by Mr. Mowll, a fact which he was confident all of them appreciated, and it gave him the greatest pleasure to tender to Mr. Mowll this vote of thanks.

Mr. A. Priestly seconded the proposition, and begged to endorse most heartily all the Chairman had said, knowing it was echoed by all the members.

The vote was received with acclamation by the members, and carried unanimously.

Mr. Mowll thanked them sincerely for their kind recognition of his services, which he had given with the greatest pleasure to the society. He had tried to make their branch a success, and though his efforts had not met, he was sorry to say, with encouragement from all the photographers he had been brought in contact with, nevertheless he thought they had to congratulate themselves that they had achieved so much towards forming a representative body. He thought they had a grievance against those photographers who were holding aloof from them at this period of their existence, who were waiting to see whether they were likely to be a power in the photographic world, and to offer immediate advantages. Such men were avoiding their duty; he felt sure he used the right word, and it was regrettable, not alone from the loss of the one man, but the effect of his example on other photographers. He thought, however, that they were firmly established now, and come to stay, and make their existence felt for the good of the profession and everybody in it. Again he thanked them most heartily for the vote of thanks.

Mr. Webster wished to call the members' attention to the sending out of proofs not paid for. He had learned from a firm who were doing amateurs' work for them that they were continually having proofs to finish, tone, and mount, and finished proofs to copy. Photographers were not generally aware, perhaps, of the extent to which they were defrauded in this way, and he hoped they would bear it in mind, and devise a safeguard of some kind.

The question of the examination of assistants then came before the

meeting, and, after a long and interesting discussion, during which various members gave their views on the matter, it was resolved to send to the parent Association the outlines of a scheme drawn up by Mr. A. F. Mowll, as a suggestion from their branch, which, it was hoped, might be helpful to the Committee in London.

It was suggested, re "issuing certificates of qualification to assistants" —

That local centres be appointed by London Committee of P.P.S. to consist of not more than five members, who shall act in the district only.

That a form of question, theoretical and practical, be drawn up by London Committee; the candidate to answer correct two-thirds to qualify.

That all candidates to pay on application for examination a fee of 5s.

That a certificate be issued to local examiners, who will fill should candidate qualify, and return to London to Central Committee, who only can use official stamp.

Any candidate who fails to satisfy examiners cannot present himself again for examination under six months from former examination and must pay on application for re-examination a further fee of 5s.

All fees to be remitted to London Committee.

This concluded the business of a very successful meeting.

THE CAMERA CLUB.

ALTHOUGH it was not exactly a photographic subject, no one could complain that Mr. Alan H. Burgoyne's paper on "Submarine Boats and their History," delivered on Monday, the 11th inst., was not opportune and up to date. But it had a photographic interest well, for many of the excellent pictures thrown upon the screen were shown for the first time in public. Most of us thought that submarine boats were so new to the navies of the world that the numbers could almost be counted upon the fingers of one hand in each country. But Mr. Burgoyne, who has made a study of submarines his hobby, was able to show that the number of such craft afloat or on the stocks is close upon two hundred. With our usual conservative notions, this country lays behind, and although we have by this policy the advantage of profiting by the experiments of other nations it is not a policy which can always be commended. Of course, Mr. lecturer had something to say about the unfortunate *A1* submarine which lately sank to the bottom with her devoted crew. He described this vessel as one of the worst models yet conceived, with a conning tower of exceptional height, which led to the disaster which cost the crew their lives. Whether the submarine came up close to the line in order to show what she could do, or whether she became unmanageable and drifted in the liner's way, will perhaps never be known, but it seems certain that by aid of the periscope the man at the look-out should have had no difficulty in seeing the big vessel approaching. The construction of submarine boats has been kept by different countries as a secret not to be divulged, and the various naval authorities would have been considerably astonished if they could have seen the photographs which Mr. Burgoyne has collected. They showed the outside, and in some cases the inside, of submarines belonging to the different nations, and if there be any secrets they are divulged, to some extent, by these pictures. The historical section of the lecture was interesting, as showing that methods of existing in submarine structures were troubling men's minds as early as the time of Aristotle — twenty-three centuries ago.

On Thursday, the 14th, a very different subject came before the club, the title of the lecture, which was given by Mr. J. A. Formoy, F.R.A.S., being "Suns, and their various stages of Development revealed by the Spectroscope." Possibly, if absent members could have known what an excellent lecture this would be, they would have attended in larger numbers, but Mr. Formoy's audience, if small, was certainly appreciative.

Commencing by showing a continuous spectrum on the screen, Mr. Formoy gave an interesting account of the manner in which the mystery of the Fraunhofer lines was gradually revealed to the pioneer workers with the prism. It is one of those charming fairy tale sciences which have the advantage of being true, and only fairy-like in their near approach to that which has been deemed to be magic.

He told how the bright lines exhibited by an incandescent metal found their counterpart as dark lines in the solar spectrum, and how it was ultimately proved that these lines of darkness showed where absorption took place by the presence of the cooler vapours of the same metals. He showed how these lines were always in one definite position on the spectrum, and how they varied in number, sodium being represented by the well-known double D line in the yellow, while iron on the other hand had about 460 lines as witnesses to its presence. It was Kirchhoff who first submitted the vapour theory of the dark lines to direct experiment, which he did by employing an iron tube five feet long which was closed at each end by a plate glass cap. In this tube he placed fragments of the metal sodium, and exposed the whole to the heat of a furnace. The sodium was reduced to the state of vapour, and by applying a prism to the end of the tube it was found that this vapour turned the bright lines into dark ones. This experiment gave the clue to the problem, and was soon afterwards discovered that the dark lines of the blue spectrum revealed the presence in our luminary of most of the metals which are known on this earth.

It was Father Secchi who noted that the planets gave the same spectrum as the sun, as might be expected, seeing that they borrow their light from him. But when he turned the spectroscope to the distant stars he found a very different state of things. Each star was found to give a different record, but some seemed to have a family likeness, and it therefore became possible to group them into four classes. For the first time it was realised that the orb of day, our beautiful sun, which had hitherto been looked upon as the principal luminary in the heavens, besides being the ruler of the solar system, was not alone in his glory. Indeed, it had to be admitted that he was only one sun amid millions, and far from being the finest, actually belonged to an inferior order of suns. The stars were stars no longer, but vast luminaries, some like our sun, some almost inconceivably hotter, like Sirius, and some which apparently were inferior to our sun. The spectroscope was able to distinguish between these various groups of suns—the brightest, like Sirius, being identified with four dark lines, due to hydrogen. The second order of suns gave a spectrum like that of our own luminary; the third order was found to give a spectrum similar to that of a sun spot, and it includes the variable stars. The fourth order of suns give a very faint spectrum. They seem to belong to a lower group than the others, and have a deep red tint.

Mr. Formoy then dealt with the development of stars from nebulae, and he showed a very beautiful photograph of the Pleiades which had nearly seventeen hours' exposure. Whereas this well-known cluster of stars seems to consist of about nine to the unaided eye, his photograph contained no fewer than 421 distinct orbs, and the principal of these were enveloped in nebulous structures, which were invisible to sight even when aided by the most powerful telescopes. The lecturer concluded his remarks by paying eloquent testimony to photography as the helper of astronomy. Without the wonderful records which it gives, the work of the astronomer would have stood still. It is wonderful to consider how the photographic plate has advanced our knowledge of the stellar universe, and its useful aid is everywhere more apparent than it is in furnishing records of the constitution of these distant suns as revealed by the spectroscope.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

APRIL 14TH.—Mr. Drage in the chair. As a reply to Mr. Bennett's criticism at the previous meeting that no advocate of lime development had or did exhibit work possessing technical excellence, the Hon. Recorder passed round an album of prints, the negative from which were made having been developed by the time method of development, the developer and time factor being modified to suit the subject and the result required. Mr. Becket did not think that Mr. Bennett condemned factorial development, but an extract from his lecture on the subject, delivered at the Camera Club twelve months ago, showed that he did. Mr. Fry was of opinion that a higher range of good results were possible with factorial development than any other method, that development by judgment often fails, and, regarding pictorial work, a far different method of treatment throughout has to be adopted than for ordinary work, as pictorial results were more a matter of personal feeling and selection than specimens of technical photography. The Recorder promised a paper at an early

date dealing with factorial or time development, promising not to speak later than nine o'clock, so that a good discussion would be possible. The affiliation lecture by Mr. S. T. Harris, F.R.P.S., entitled "Natural History Photography," was read by Mr. Freshwater, who incidentally mentioned that the supplementary base board so strongly recommended by Mr. Harris was his invention.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

APRIL 18TH.—The President, Mr. C. F. Dickinson, in the chair. Some discussion took place as to the competitions for affiliated societies and the position which it was considered the society should occupy in these events. Formerly the society took a very active part in such matters, and it was strongly pointed out that if the old interest was revived the South London could regain the place it previously occupied.

A lecture on "Majorca," written by Mr. G. E. Thompson (of Messrs. Elliott and Sons, Barnet), and illustrated by slides, was then read. The writer travelled by boat from Barcelona to Palma, which is a large town for so small an island. A number of views of the town and surrounding country were shown, curious windmills like gigantic spiders' webs, the old Moorish Palace, and the Stalactite Cave of Arta, where "the maiden-hair fern hangs in profusion from the roof."

RICHMOND CAMERA CLUB.

APRIL 14TH.—Ladies' Night.—Mr. Sargent gave a lecture at the Freemasons' Club on "Java, its People and Temples," illustrated by a large number of lantern slides. He first gave a brief outline of the successive occupation of the island by the Dutch, the English, and again by the Dutch. He afterwards gave a general description of the country and its climate, accompanied by views in town and country. He described its ranges of lofty volcanic mountains, and in connection with these he gave an account of the terrible Krakatos eruption in 1883, which occurred during the time of his residence in Java, and by which upwards of 37,000 lives were lost, enormous damage done to property, and whole towns and villages swept away. The lecturer described the agricultural work of the island in which most of its 22,000,000 inhabitants are engaged, and gave details of the cultivation of rice, sugar, and coffee. He gave particulars of the costume, customs, and mode of living of both Europeans and natives, and afterwards described and showed a number of views of the remarkable old Buddhist temples which abound in some parts of the country, the history of which has been entirely lost, but which are rich in fine carving and sculpture, and which constitute one of the most interesting features of the island. At the conclusion of the lecture a few specimens of the native hand-painted "sarongs," garments worn by the Javanese and adopted by Dutch ladies, were passed round for examination by the audience.

Patent News.

The following applications for patents were made between April 5 and April 9, 1904:—

Dish.—No. 8040. "An improved dish for use in photography." Robert Beel.

Developing Apparatus.—No. 8069. "An improved apparatus for the manipulation of photographic plates and films without the aid of a dark-room." Elea Luboshey.

Backing Sheet.—No. 8070. "A light tight envelope and backing sheet for one or more photographic plates and films, and suitable for daylight charging." Elea Luboshey.

Cameras.—No. 8132. "Improvements in or relating to photographic cameras of the character known as 'Magazine cameras.'" Complete specification. Charles Tyler and England Bros., Ltd., and Samuel Dunseith McKellen.

THE PICTURE POSTCARD.

"CANDIDATES for the new Geographical Tripos at Cambridge will be expected to show proficiency in identifying picture postcards of various places, scenes, and landscapes. Travelling students will have to forward to the Board of Studies complete sets of postcard views of all the countries they visit.

"It is no longer customary for callers to leave visiting cards. Postcards embellished with portraits of yourself or your family are distributed instead. Cards of humorous design, however, must be used with caution, unless they are intended as P.P.C. for good.

"A large extension of premises is about to be made at the British Museum. The new building, as well as the old, will be entirely given over to the storage and display of picture postcards. The previous collection of books, etc., have been sold *en bloc* to Mr. Pierpont Morgan, thereby defraying a part of the immense cost of the new national treasures.

"Sets of the more valuable cards may now be bought on 'The Times' Instalment System. You pay five shillings down and a guinea a month subsequently.

"A postcard 'Who's Who' will shortly be published, containing only those celebrities whose portraits have been thus immortalised. Such persons will be entitled to affix P.W.W. to their names, this distinction ranking next after the Order of Merit.

"The next General Election will be conducted entirely by postcards. Everyone will send a political specimen to everybody else. The revenue will thus be so vastly augmented that there will be no Fiscal Question left to solve. To this happy consummation the Cobweb Cartoons, the Little Loaflets, the Starvation Squibs, the Famine Fancies, and other alluring and alliterative sets, are expected largely to contribute. Candidates' addresses are to be printed on one side only of the cards, thus ensuring desirable brevity, if not wit."—"Punch."

News and Notes.

PHOTOGRAPHIC SURVEY OF THE COUNTY OF SUSSEX.—For some time past there has been a desire amongst members of the Sussex Archaeological Society that an effort should be made to record permanently the very many objects of interest which the county contains, or has contained, and to effect this it is proposed that a Photographic Survey for the county, similar to those already organised and working, *e.g.*, in Warwickshire and Surrey, should be inaugurated. The Sussex Archaeological Society has recently obtained about 400 negatives, 10 in. by 8 in., taken twenty or thirty years ago, of churches of Western Sussex; many of them are of churches which have been since rebuilt or much altered, and these furnish a sufficient proof of the great necessity for the preservation of a record of ancient buildings etc., still existing. This acquisition forms the nucleus of the collection which the Committee for the Survey hope to make. Professional and amateur photographers and societies possessing negatives, lantern slides, and prints of interest, either mounted or loose, are invited to furnish particulars of them to the hon. secretary, with a view to their being catalogued and for the provision of copies. The Committee would furnish a schedule of the objects to be photographed, and provide where necessary cards of introduction to facilitate access to the desired objects. At the same time, this schedule would not be considered exhaustive, but as open to addition or modification as circumstances or local knowledge may dictate. Full particulars will be gladly furnished by the hon. secretary, J. C. Stenning, Steel Cross House, near Tunbridge Wells.

THE Photographic Survey of Kent was well founded at the inaugural meeting held at the Museum, Maidstone, on Saturday, April 16. Mr. H. Snowden Ward, in outlining the history of photographic survey work in the kingdom, reported letters of suggestion and support from the National Photographic Record and Survey Asso-

ciation, the Photographic Survey and Record of Surrey, and many photographic and scientific societies within the county, and read a set of suggestions for rules and constitution. The objects of the record and survey were stated to be—(a) To obtain permanent photographic pictures of objects of literary, historical, archaeological, and scientific interest; of current customs, costumes, and events; and of prominent men and women within the county of Kent; and to deposit such pictures, with explanatory notes, in the County Museum, Maidstone, and in other places where they may be suitably preserved and readily accessible to the public under proper regulations. (b) To facilitate intercourse between photographic societies and archaeological or kindred societies, and to make arrangements for promptly photographing objects which may be only temporarily accessible. (c) To assist in the exchange of prints and in their acquisition by scientific societies wishing to make collections dealing with their own subjects. The provisional committee includes:—Mr. Golding (Sevenoaks), J. Rev. E. W. Banks (Longfield), Rev. Gardner Waterman (Loose), a Rev. C. E. Woodruff (Faversham), Dr. Abbott (Tunbridge Wells) (Sheerness), Harry F. Wingent (Rochester), H. Witcomb (Maidstone), E. W. Andrew (Bromley), Hubert Benstead (Bearsstead), Joseph Chamberlain (Tunbridge Wells), J. C. Dunk (Maidstone), H. J. Ellis (Maidstone), J. Hepworth (Rochester), Chas. Igglesden (Ashford), Jas. Roach (Sidcup), H. E. Turner, B.Sc. (Folkestone), Ben. G. Watts (Sheerness), Harry F. Wingent (Rochester), H. Witcomb (Maidstone), and Norman Wolters (Catford). A sub-committee of five members was appointed to deal with the rules immediately, and the meeting closed with thanks to the chairman. In the afternoon the sub-committee completed a draft of the rules, of which copies may be obtained by intending members on application to the provisional secretary, H. Snowden Ward, Hadlow, Kent.

THE New Gallery.—Mr. C. E. Hallé, Mr. J. Comyns Carr, director, and Mr. Leonard Lindsay, secretary, were on Monday evening entertained by the exhibitors at the New Gallery at a complimentary dinner at the Café Royal. Lord Monkswell presided over a large company which included, in addition to the guests of the evening, Sir W. Richmond, R.A., Mr. J. Sargent, R.A., Mr. C. Perugini, Mr. Spielmann, the Hon. J. Collier, Sir P. Burne-Jones, Mr. A. East, Mr. D. Carr, Mr. J. MacWhirter, R.A., Sir Wyke Bayliss, Sir J. Lint, Mr. C. Whymper, Mr. R. W. Allan, Mr. T. A. Brown, Mr. Brough, Mr. W. Crane, Mr. S. Mclen Fisher, Mr. J. Coutts, Mr. C. Hetherington, Mr. E. Parton, Mr. J. L. Pickering, Mr. C. Smithers, Mr. E. Stott, Mr. A. Stokes, Mr. L. Thomson, Mr. Thorne Waite, and Mr. G. Wetherbee. The Chairman, in proposing the health of the guests, said that exhibitors at the New Gallery wished to do them honour because of the good work they had done both for the New Gallery and for art in general. The institution of this gallery was due particularly to Mr. Hallé and Mr. Comyns Carr. The task which they then undertook was no small one, for they had to combat the ingrained philistinism of the British nation. It was founded for the delectation of the lovers of real and true art. It induced painters of the very first eminence to exhibit at the New Gallery, and, without offending anyone, he might say that the pillars of the new Gallery were, at any rate at its inception, Sir Burne-Jones, Sir L. Alma-Tadema, and Mr. Watts. The New Gallery was cosmopolitan, and opened its hospitality to foreign artists renowned. It had done much to inform and instruct public opinion in matters of art, and to a great extent it had done so successfully. The however, could not conceal from themselves that a great deal yet remained to be done. Mr. Hallé, who first responded to the toast, claimed that the New Gallery was the handsomest and best lighted of all the galleries in London. Mr. Comyns Carr, who also replied, said that he represented the lay element among the guests, the introduction of the literary element into art. He was not prepared to hide his idea about the literary spirit, or to make any confession of weakness in that regard. He believed that the literary spirit was never the condition of any artistic achievement, that unless a man was an artist the literary spirit counted for nothing, but that if a man was an artist there was no burden of the literary spirit which he could not bear. Every great master who had been a great general towering above his technique had, in his opinion, contrived, beyond the mere message of his art and the perfection of his technique, to convey some message of world-wide significance. Mr. Lindsay, replying, expressed the hope that the New Gallery might become a permanent institution.

Correspondence.

MODERN COMPETITION IN PHOTOGRAPHY.

To the Editors.

Gentlemen.—It is just a year ago (April 17th) I wrote you under this heading, quoting prices of chemicals fifty years ago—to wit, pyro per dram, hypo 3s. lb., bromide of potassium 4s. oz. I then promised at some future date to give quotations of prices obtained at that date, to enable the younger generation to compare. I will only give a few extracts from an old ledger—viz., 2 portraits, coloured water in Passepartouts, fifth size (i.e., half-plate), 15s. each; 2 portraits, second size, in cases, 3½ by 2½, 7s. 6d. each; then in 1856, stereo views of house, 15s.; 1 stereo of lady horseback, 4 copies, s.; 2 stereos of lady and dog, 10s.

It will thus be seen the rule was to charge all copies alike. Then I bought all chemicals direct from makers, and albumenised our own paper. As all the stereo work was done some miles from home, involving the necessity of appliances for preparing and developing on the spot being taken there, I think it will be seen how reasonable the prices were, and one asks, Were these times better than now? I say yes, for the photographer, because he had nothing like the present competition.

On April 24th, "Postcard" replied showing how he filled up his home, and stated photographers were largely to blame for the competition of the photo chemist and wholesale view publishers, rough confining themselves almost exclusively to portraiture, and stances one direction in particular—viz., postcards. He stated collotype postcards are supplied by these outside men at from 35s. to 50s. 1,000, while the local man can get them printed from his own negatives at from 18s. per 1,000.

Singularly, within a month, a traveller representing a large photographing establishment called on me to solicit orders, and put into my hand a circular with a large extract from postcards and letters, and on this I found quotation for postcards—viz., printed in sets of twelve, 1,000 each view, 18s. 6d. per 1,000; 500 each, 20s. Now from these figures I wish to point out where the photographer, as a whole, cannot compete. First, I would say, that single thousands can be obtained, produced by outside men, at considerably below 35s., while 50s. would represent coloured ones, i.e., from his own negatives; 35s. would represent those from the publisher's negatives, but he can buy these at 3s. per 100, not necessarily by 1,000. I am not writing by way of complaining personally. I only want to make my point clear re competition affecting the photographer, mainly, perhaps, in provincial towns. Competition is rife in all trades, but the photographer is more handicapped in his work than others at the present than he was fifty years ago. Then he could buy direct from the maker whatever he wanted at the best price ruling; now, if he does not happen to be in the ring, he has to pay at least 15 per cent. more than the local chemist, and, in some cases, 23½ per cent. more for the goods he is using every day, and yet he has to compete in some cases with the chemist in local views, postcards, and portraits, and in developing and printing for amateurs, and the P.P.M.A. would tell you the chemist should have more discount because he stocks goods. To this I reply: Yes, he does stock some, but it can be proved in many provincial towns his stock is most meagre. He may have one maker's plates and paper, but that is all outside of this. He can get them for you in two days." Yes, so can the photographer. I ask, then, Why should the chemist get more discount? What does it matter to the maker who uses his stuff? Let us, as a profession, have free trade and no favour; then would be seen who the cause of the largest sales, and the profit would go in the right pocket. This has gone to greater length than intended; perhaps a year's silence may atone a little. Thanking you for past courtesy. I am, yours,

OLD PROFESSIONAL.

April 19, 1904.

THE ROYAL PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen,—I am a simple country professional, and have for some years contributed my subscription to the Royal Photographic Society, not because it was any use to me, but that I thought an institution of that kind should be supported in the interest of all photographers. On a recent visit to London, I went for the first time to the headquarters of the Society, and the impression made on me was most unfavourable. I found the permanent collection hanging at various angles, dust covered, with the gloss coming from some of the frames, and many of them more or less open at the corners, seemingly falling to pieces. Then, inspecting the work-rooms, I found the same untidiness and neglect, to use no harsher terms. It seems to me that such a state of affairs is most discreditable to what should be our premier Photographic Association, and I cannot understand such evident mismanagement. It is very evident to me that I have been deceived in my belief of the character of the institution I have been supporting, and shall hesitate before renewing my subscription. I shall also dissuade a brother professional from becoming a member at present.—Yours faithfully,

A COUNTRY PROFESSIONAL.

[Our correspondent must have been singularly unfortunate on the occasion of his visit to the Royal Photographic Society's house, which, in an experience of it of several years, we have invariably found well administered and in good order. It is a very poor spirit indeed which sees in a little temporary untidiness a sufficient pretext for resigning from a useful and progressive society. We hope our correspondent's "brother professional" is endowed with sufficient independence of judgment to enable him to resist "A Country Professional's" silly dissuasion. We know of no society of the character of the Royal, which, in return for the humble subscription of £1 1s., gives its members such good value for the money.—Eds. B.J.P.]

THE PIONEER GLOW LAMP.

To the Editors.

Gentlemen,—I am sure you wish to do justice to the British inventor when he is first, so I enclose you the true account of the invention of the "Glow Lamp," more especially as it was Mr. Swan (who is mentioned in your paper last week). In fact, Mr. Swan very incautiously showed and explained his lamp before he should, and it was reported to Edison. That, of course, is a detail; the point is that Swan made the incandescent lamp possible, and I think that all photographers should know this.—Yours truly,

W. J. SPURRIER.

1, Stanley Place, Moseley, Birmingham.

April 15, 1904.

[The account to which our correspondent refers is reproduced on another page.—Eds., B.J.P.]

"CINEMATOGRAPH PATENTS."

To the Editors.

Gentlemen,—I had the pleasure to be operator to Mr. Friese-Greene in 1890, and can testify to the truth of his claim to be the original inventor of the cinematograph. During the early part of that year he told me concerning his ideas of producing living pictures, and I frequently developed the spools of films for him, which were taken with his camera.

As far as I can remember (although I never used it personally) this latter instrument was capable of making four hundred consecutive exposures per minute.

I feel it a duty to corroborate the letter of my past chief, who has ever my respect, both for his geniality as an employer and his remarkable scientific skill, which seems always to have surpassed his luck.—Heartily yours in the work,

A. WHITING.

April 15, 1904.

To the Editors.

Gentlemen,—In your last issue Mr. Friese-Greene, referring to a paragraph in a previous number, expresses his surprise "that a journal of your standing should mention 'Beale's Chœreutoscope,' etc., 'as cinematographs,' and he takes pains to point out that you ought to know better. He does not seem to have read the paragraph in question very carefully, for it merely says in reference to the chœreutoscope that "There is no doubt at all that the germ of the

modern cinematograph is found in this primitive apparatus." In support of this view, I beg to quote from the introductory chapter of "Animated Photography," by C. M. Hepworth (Hazell, 1897), in which it is stated that in the chrestoscope "was embodied a principle without which none of the cinematographs of the present day would be of any use." The pictures were "made to pass through the lantern in a series of jerks with a pause between each," and "immediately in front of the picture was a little shutter which descended and cut off the light at each movement, and immediately reopened again as soon as the picture had come to rest." If Mr. Green's machine did not embody this principle, it is difficult to see how he can maintain that all existing cinematographs are infringements of his patents, as stated in his letter of protest to the "Society of Arts Journal," which you reproduce at length on page 314.—Yours, etc.,

A CINEMATOPHAGER.

April 15, 1904.

SOME NOTES ON THREE-COLOUR WORK.

To the Editors.

Gentlemen,—I am truly sorry that Mr. E. J. Wall took my notes on three-colour work as a personal reflection on his translation of Dr. Eder's work. He being only the translator, I do not think he has any right to take the attitude assumed in his letter of last week's issue. Mr. Wall says, Why drag in orthochrome, which, two years ago, when Dr. Eder's notes were written, was unknown? I say, Why trouble, then, to translate an out-of-date article which, as it does not include present-day dyes, is of little use except to fill space? Possibly his translation is a mere trifle thrown off in an idle hour, and is not to be taken seriously!

Now, I do not for a moment claim to be an authority, but as I have put in six to ten hours a day at colour sensitising and three-colour work for the past two years, in a laboratory equipped regardless of expense, I think I can fairly claim to be in a position to write a few notes on colour work, and detail an account of the ways in which these purple-black dyes can cause confusion. My experiments, moreover, have all been done on a manufacturing scale, with a view to turn them to ultimate commercial use, and therefore I venture to think that an account of my own experiments is as valuable as that of a more theoretical nature.

With regard to giving no indication to the colour distribution in my spectrographs, the Zeiss scale which I invariably use in contact with the plates exposed was lost in the reproduction, but any man who is familiar with the spectroscope will be familiar also with the distribution of colour in the visible spectrum.

If Mr. Wall thinks my notes bordered on the impertinent, I offer my apologies. No one, I think, has more regard for Mr. Wall than myself, for he was the first to give me a helping hand in real photographic work. But for authorities—and he can include my humble self if he please—I care not one jot. Let the BRITISH JOURNAL OF PHOTOGRAPHY give us notes on colour work, on everything, that can be turned to practical account; we look upon it as a scientific and commercial journal, the journal for manufacturing and business photographers; and if on prolonged trial I can turn Wollschwarz 4B to practical account to my own satisfaction, the BRITISH JOURNAL will be the first to receive a detailed account of the work.—I am, yours faithfully,

T. THORNE BAKER, F.C.S.

1, Station Parade, Willesden Green, N.W.

PHOTOGRAPHIC BURNISHERS.

To the Editors.

Gentlemen,—In reply to the question addressed to you by J. Spencer, there seems to be no doubt that the maker of the burnisher he wants is Carl Seib, whose business is located at 5, Grillparzer Strasse, Vienna. The burnisher is called the "Fernande."—Truly yours,

P. EVERITT.

88, Evering Road, London, N.

PSYCHIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—Apropos of your append to Mr. H. Blackwell's letter re psychic photographs, I may say I am as deeply interested in the so-called spirit-photography as I was in the early seventies. I daresay

many of your readers may remember what the late J. T. Taylor published in your pages, and of my experiments, that were also published in the "Medium and Daybreak." I may reiterate that I threw out many challenges to mediums and others offering sums of money, in some cases £20. None of my offers were accepted. I do not think I have had the pleasure of meeting Mr. Blackwell, but first I thought he was a tout to a professed spirit photographer; must be mistaken. If Mr. Blackwell means well and investigation I am willing to assist him or any number of mediums to the extent of £50 or £100, my opponents to select five experts, I to appoint five including myself, the conditions to be subsequently arranged. Show the majority of jurors decide that they have proved their case, will forfeit the aforesaid sum, to be given to some charity. On the contrary, I will expect the opposition to contribute a like amount to the said charity. I may mention that the late J. T. Taylor, at I attended, our first sances together, and we were in each other's confidences, more especially regarding my method of manufacturing shams. Conversations we had during his later years, tended to convince me that he wavered in his opinions regarding certain results. Apart from this subject, I have had an interesting and busy winter photographic campaign in Greece and Turkey. I hope to return home in about a month, when I will have pleasure in giving an exhibition of my photos.—Yours truly,

A. L. HENDERSON.

Corfu, Greece, April 11, 1904.

KEEPING QUALITIES OF PLATES.

To the Editors.

Gentlemen,—Having used gelatine dry plates since they have been introduced commercially, I think I can say that I have had some experience with them, and I must say that they have proved rather more satisfactory than not, so far. I have had, as probably so have others, occasional trouble with them, but I never could find a maker of them to admit that it was his fault or the fault of his plate so that I begin to look at the manufacturer as something like an infallible being, and I would like to continue on that line; but I would also be pleased to have some more rational explanation why plates do not keep as well now as they used to. I may admit that when one goes to extreme sensitiveness the keeping quality may be impaired, but this should not be the case with any ordinary sensitiveness, and by that I mean the plates that will allow the taking of views in 1-20th, or even 1-50th of a second, with an ordinary wide angle lens of say, 8in. focus. These plates used to keep very well and just as well as slower ones, not only in packages as sold but also when kept in the holder as long as one year, without the slightest deterioration. However, not making special trials to the effect, my experience has proved it to my entire satisfaction. I have found that edges, where separated by paper, showed marks on the plates, but this would not extend more than 1-16th of an inch further at least before 1895 or thereabouts, but since then this trouble began to show. Why? (I am always speaking of moderately rapid plates.) Not being able to explain this in a satisfactory way, it was hinted that the fogging of plates came from defective holders. These holders having some brass about them and some defective hinges and joints it could be believed, and may have been true in some or many cases, but with many holders whose shutters draw out only partially, this trouble may easily arise. This was then corrected more or less, and a remedy given until the question arose again, and then it was the fault of the interior finish of the holders and the wood. Then the question arose, why would old wooden holders, having no metal fittings, also on the plates in such a foggy way? I am using such holders, and they date back as far as 1875, therefore should prove dry and inert, and they have shown this to be the case until 1898, when at once plates would show foggy rims all around, from 4in. up to 2 1/2in. or more according to time they were left in such holders (size of plate, 10 by 12). The answer to this was given not very long ago and not secretly to me, but in the B.J.P., as follows:—Plate holders will fog plates, whether said plate holders were old or new, as there was no telling when these wily plate holders would put it into their heads to go back on the poor plate manufacturer first, and afterwards on the owner of them, and play false. Maybe that plate holders have minds of their own, and will admit of some plates and not others. Whatever the case may be, it remains to be explained why plate holders will remain good for 23 years 7 months and 14 days, and

the next day spoil Mr. So-and-so's plate, just in spite of—what? become unmanageable unless! Unless! and just here comes my question. As long as I used moderately rapid plates they would keep well in holders and in packages; now these will do so no more. As I am using now for convenience slow plates, they act just the same as they used to, and for years; they keep well, and just as well in packages as in the holders. Is it the fault of the plate, or the wood of my holders been restored to good health by some magic interference? Who can tell, in these times of spirits and phantoms? One thing I am sure and positive, no manufacturer of plates is to blame for this state of things; but who is?—Yours very truly,

ALBERT LEVY.

Amiens (Seine),
April 17, 1904.

"FALLOWFIELD'S Courier" is the title of the little publication to be issued monthly in the interests of photographic dealers by the well-known firm of Charing Cross Road. It will deal mainly with the latest trade novelties, etc.

The Marquis of Northampton will open for the British and Foreign Astronomical Society on Friday, May 13th, the Observatory and Equatorial scope, just completed by Sir Howard Grubb. This addition to King Edward VII. Nautical School is the gift of the late Louisa Ashburton. The inauguration will be followed by a conversazione astronomical lecture by Mr. E. Walter Maunder, of the Royal Observatory, Greenwich. The instrument is placed on the top of the Observatory's new headquarters at Limehouse, which was opened last year by the Prince of Wales.

The Travelogues of Mr. Burton Holmes.—The Travelogues, which have now the attraction at Queen's Hall for a short season, cannot be better described than the gist of a journey, leavened with information, seasoned with humour, fashioned in literary form, and embellished with pictures that would be hard to beat for both technical excellence and artistic beauty. Suiting the picture to the phrase, Mr. Holmes affords that universal yearning to see and know the wonder and variety of the earth-wide realm of the modern traveller. The telling of the story and its pictorial presentation move on in perfect harmony, producing the illusion of actual travel, which is considerably heightened by the realistic colouring of the fine photographic slides which are projected on the screen. These pictures are interspersed with a selection of animated pictures that help the delightful sense of "being there" amazingly. Mr. Burton Holmes' travelogues should prove as successful here as they have been in America. His present series includes "The Yosemite Valley," "The Yellowstone Park," "The Grand Canyon of Arizona," "Alaska," and "The Golden Klondyke." His illustrations, with a few exceptions, are from negatives made by Mr. Holmes himself, and the colouring of the slides, to which undoubtedly much of the success of their presentation is due, is the work of Miss Katherine Gordon Breed and Mrs. Helen E. Stevenson. Motion pictures made expressly for each travelogue are by Mr. Holmes and Mr. Oscar B. Depue, and speak well for the quality of taking and projecting machines employed. We understand the Kinetograph bioscope supplied by the Chas. Urban Trading Co., Ltd., is used by Mr. Holmes on these travelogue tours.

The Chronophone.—At the Grand Theatre, Fulham, on Thursday (April 14th), a private demonstration of speaking animated pictures—known as "the Chronophone"—was given before a full house, a very favourable verdict indeed was passed by those present on this latest combination of the phonograph and the cinematograph. Chronophone is the English edition of the Gaumont-Messter patents, already considerably exploited in Germany under the title of "the phonophone," and the secret of its success seems to lie in the perfect synchronisation between the talking and projecting machines. It appears to be perfect, and is, we are told, effected by electrical means. Every tone synchronises with its corresponding movement on screen in a manner that appears at first uncanny, but opens up possibilities in the way of production of not only single scenes, but entire plays. The programme presented by the Chronophone on the present occasion included many realistic scenes. One incident was the drilling of a number of soldiers, the words of command ringing out being immediately acted upon by the soldiers. A song from Lohengrin formed another item, and a laughing, jostling crowd at a race-course, a xylophone trio, and a comic coon song were other successful features. Given a really good phonograph, or gramophone, of sufficient power to aid the illusion, and the best films obtainable of the subjects portrayed, a successful future may be predicted for the invention.

Answers to Correspondents.

- All matters intended for the next portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- H. E. Howorth, 16, Dock Street, Fleetwood. Photograph of Life-boat Launch at Fleetwood.
- W. Eastwood, 17, Market Square, Lytham. Photograph entitled "Lost."
- P. M. Bright, Chummen, Lansdowne Road, Bournemouth. Nine Photographs of Gipsy Smith. Photograph of Gipsy Smith with Wife and Daughter. Two Photographs of Gipsy Smith and Daughter. Three Photographs of Combined Photograph and Drawing of Gipsy Smith with View of Cabin and Tent.
- J. P. Blair, Crystal Palace Studio, Chapel Street, Petersfield. Photograph of a Tree Struck by Lightning.
- J. MacMillan, 513, Union Street, Aberdeen. Photograph Copied from Oil Painting of the "Doubting St. Thomas."
- E. T. Bush, 94, Spilott Road, Cardiff. Photograph of Miss G. Jenner.
- E. C. (Twickenham).—We regret we cannot give you the address you require, the letter having been destroyed.

J. H. REDWOOD.—We believe the print meter you mention was one made by the author of the article in question. We do not think it is on the market.

LENS QUERY.—B. JARROW writes: "I have a lens with the enclosed monogram on it. Would you kindly inform me who is the maker?" In reply: The maker of the instrument is, we believe, Valentin, Paris.

ADDRESS WANTED.—E. T. DENNIS.—We regret that we cannot give the gentleman's address as we do not happen to know it. We do not reply to correspondents by post. Why not write to the Editor of the journal that reproduced the pictures you mention?

"JOHANNES" asks: "Is there any book published dealing at all exhaustively with the investigations of Messrs. Hurter and Driffield?" In reply: "The Photo Miniature, No. 56," published November, 1903, deals with the Hurter and Driffield system.

J. W. COOK asks: "Would you kindly inform me where photographic caravan studios can be had on hire?" In reply: We are unable to say where caravan studios can be rented. Occasionally they are offered for sale in our advertisement columns. The best way would be to advertise.

BLIND QUERY.—"STUDIO BLINDS" says: "I should feel greatly obliged if you would kindly inform me as to what blinds I should require for studio with a north-east light? I am leaving sitters' end more at east of studio, and I understand I should want light reflected from other end. I can't take sitters at north end on account of door being placed to face the main road." In reply: For a north-east light pale green or medium blue blinds will be as suitable colours as any.

RESTORING STALE PLATES.—A. DEBENHAM says: "Will you, please, inform me if a number of plates, consisting of old stock, might be made reliable and the sensitiveness ensured by immersion in bromide or other solution, and if so, what would be the best?" In reply: In practice we think you will not find "the game worth the candle." You might try the following bromide of potassium two drams, chromic acid one dram, water one pint. Immerse the plates in this for from five to ten minutes and then thoroughly wash and dry. You must expect to find the treatment somewhat slow.

"DAFFODIL" says: "I have specimens of daffodils to photograph next Saturday, and I would be glad if you can let me know the following. I know they should be taken with a screen but I have not one:—(1) Daffodils being yellow, what colour background should I use? (2) Would Edwards' Iso Plates give sufficient detail in the yellow flower? (3) Using ordinary Iso Plate, Stop 16, and

background you suggest in good light, what exposure would be right?" In reply: A screen would certainly be of great help in securing the correct colour values. Why not get one? (1) A dark background would be best. Dark brown paper without creases would serve. (2) With full exposure, yes. (3) A lot depends on what you call good light, but approximately ten seconds.

SITUATION WANTED.—I have a cousin who wants to get a situation as lady receptionist at some photographer's in London, and also to learn some branches of the trade. Below are the questions which I should be much obliged if you would be so good as to answer:—(1) Is it necessary to pay a premium? (2) Is it not possible to get a situation at a small salary? (3) What are the best shops to apply to? They must be in London and not to live in." In reply: (1) It is usual if the lady knows nothing of the business. (2) Rather unlikely with one who knows nothing of photography. (3) The best way is to consult the "Situations Vacant" column of the Journal, or to advertise in the column devoted to "Situations Wanted." We do not reply to queries by post.

PLATINUM SOLUTION.—"LILY" writes: "As a practical lady amateur I make my own platinum toning bath. This time I have, however, made a stock solution, 15 grains plat. to 15 ozs. water (1 gr. to 1 oz.). I have put it in a clear glass bottle and left it in the light. It has now gone as black as ink. Should it do this, and will this affect its working when I use it to make up a solution to tone matt collodion paper?" In reply: If the solution is in the condition mentioned we expect that it is useless—the platinum being precipitated. We surmise that the precipitation is not due so much to the action of light as to the use of impure water in making the solution—or the two combined.

TONING ALBUMEN PAPER.—"ALBUMEN" writes: "A little information will much oblige respecting toning of albumen paper. What is the cause of deposit in gold acetate bath? I use ready sensitised paper and wash prints with small amount of bicarbonate of soda. Would you advise using bath only? I always make up with distilled water. Also, tell me is it necessary that fixing bath should be stronger than for P.O.P.?" In reply: There should be little or no deposit. It will be well, if carbonate of soda be used in the washing water, that the excess be washed out of the prints before they are put into the toning solution. The bath may be used several times if fresh gold be added at the end of the work. Fixing bath; should be from three to four ounces of hypo to the pint of water.

MEGALETHOSCOPE.—W. E. MANNING writes: "I have one of the original 'Megaletoscopes' made by Ponti of Venice in the middle fifties, in the best preservation, and complete in every detail. With it are many photographs of Venice, Rome, and Florence of the period, specially treated for viewing by direct or reflected sunlight, or by artificial light. The 'Encyclopædic Dictionary' describes it as 'an improved form of stereoscope in which the photograph is considerably magnified, and an increased appearance of sphericity obtained.' The article is a large and handsome piece of furniture, the photographs measure 14 in. by 10 in., and the lenses are large and very powerful. Do you think it would interest a collector of photographic curiosities?" In reply: The apparatus is certainly very interesting, and many, no doubt, would like to possess it. We should recommend you to advertise it if you wish to dispose of it.

FLASH-LIGHT POWDER.—"SMOKER" asks. "Can you give me a formula for a smokeless flash-light mixture? Having frequently to do this kind of work (at dinners, etc.), I should esteem it a great favour if you can oblige me with one. I should be glad if you would say whether it would be safe to keep it ready mixed. I am at present using Bayer's Powder, and although it gives off considerably less smoke than many other makes, I should like a mixture which generates even less, as I understand one or two firms make little or no smoke in their operations." In reply: We know of no formula for a powder that will give off less smoke than that mentioned. Compounding flash-light mixtures in the hands of those who do not understand the nature of the materials they are dealing with is a dangerous operation, and has led to many serious accidents. We should advise you to leave that work alone. "Argentorat" is a very good flash powder we can recommend.

PARAFFIN CASK.—BATTERY.—"DOWN SOUTH" says: "(1) I have, for

storing water in dark room, a cask—capacity about five gallons. The same has been used at one time for hold paraffin oil. When I fill the cask with water I find upon drawing off that traces of the oil are present. Can you, please, give your advice if I can use anything in the water to kill the oil which will not hurt plates, P.O.P., platinotype, or brom paper? Will the oil in water at present hurt the above papers etc., for washing purposes? (2) Some time ago, under 'Cathedra,' I saw a suggestion for the re-charging of carbon which have run out, and making same good for work again. Will you, please, quote formula for same, as I have a lot of waste carbon cells which, if formula works well, will save me considerable expense?" In reply: (1) It is very undesirable that the water be contaminated with paraffin oil, and it is a little difficult to get it out of the wood. We should advise you to treat the cask with a pretty strong solution of washing soda, and let it stand for a few days, and then well rinse with clean water. (2) We do not, for the moment, call the article to mind, probably you refer to a Laclanché battery. If so, you might empty the glass cell and soaking the carbon one for a day or two in clean water and then let it dry for a few days. Then charge with a saturated solution of chloride of ammonia.

MR. EDMUND MACRORY, K.C., died on Monday morning of cancer, after a long illness. Mr. Macrory, who had long retired from practice, was a well-known authority on patent law.

ART IN GERMANY.—Just now it seems, according to the Berlin correspondent of the "Standard," writing on Thursday last week, that there is a pretty little war going on between the artists of Germany and the question was raised in the Prussian House of Deputies as to "What is Art." A similar question has been raised here in connection with a certain style of photography, but that is by the way. It seems that for some time past there has been discontent in German art circles at the somewhat ruthless way in which the Prussian Government has put its veto upon the artists of the Secessionist School. The term Secessionist School in Germany is what is generally known here as the Impressionist School. Dr. Fräger in his speech in the House asked what was Secession? So far as he understood the term it meant secession from routine and from the old regime, and he complained that the Prussian Government treated the Secessionists harshly from the fact that the committee who purchased for the National Gallery excluded a work by a very clever painter, merely because of belonging to the Secessionist School, and added that the Prussian Minister of Art and Education should not forget that over the National Gallery stands the words, "To German Art," and not "To Prussian Art." The Minister of Art and Education in his reply assured the House that equal rights were accorded to all those who represented that which is truly artistic. The question at issue, however, "What is really artistic?" He added that on this point he was, at juncture, unable to discourse at length. This question of schools in art has been a vexed one in Germany, as it has been with reference to photography in England for some years past, and seems still to be a long way from settlement. It is pretty generally understood in art circles that the German Emperor is by no means an admirer of the Impressionist School of Art.

EX CATHEDRA.

Photography and surveying. The problem of executing virtually instantaneous surveys of a locality by means of photography possesses an easily-understood fascination to many experimenters, but, though certain amount of success has attended the efforts made to combine photographing and surveying, it must be confessed that it is very limited. At the present time there are some authoritative balloon ascents being made with this object in view, and lately an announcement has been made that progress is likely through a paper which has been communicated by Dr. N. Herz to the Vienna Academy on a generalisation of the problem known as the "problem of eight points." We read in "Nature" that it may be stated as follows:—"If from any four points the twelve angles subtended by four objects are measured, or if from any three points the twelve angles subtended by five points are measured, then the relative positions of the eight points are completely determined. The importance of the problem is obvious in connection with the photographic survey of unexplored districts, as by comparing the relative positions of the same five objects on those different plates a plan of the region can be constructed with greater precision than is possible with sketches."

* * *

Photographic effect of radium rays. Our readers may remember the accounts published some time ago of photographs produced by passing an electric current through coins placed on a dry plate, the result being a distinct impression of that face of the coin that was in contact. A somewhat similar effect has been produced by the use of radium emanations in lieu of elec-

tricity by Mr. Henry Stroud, who, writing from the Durham College of Science at Newcastle-on-Tyne, sends particulars of his experiments to "Nature." He says the coin or other object is placed directly in contact with a photographic plate, which is enclosed in an envelope opaque to light. A few milligrams of radium bromide, contained in the usual mica-covered box, are placed some distance above the plate and the whole left for several days. After development it is found that a clearly-defined picture is obtained of the portions in relief of the under side of the coins. Pictures have thus been obtained of the portions in relief on silver coins (half-crown, sixpence, threepence), also of a name engraved on a mother-of-pearl seal. Ten days was the time of exposure, when ten milligrams of radium bromide were placed six inches above the threepenny bit. Ten days also in the case of half-a-crown, when five milligrams were placed 1½ inches above the plate. These effects were first shown by Mr. Stroud at a lecture given by him at the College of Science, Newcastle, and have been shown by him at subsequent lectures.

A New Source of Radium.

It pays the mining expert to extract gold from ores containing only a few penny-weights to the ton, the processes adopted involving the use of the old photographic chemical cyanide of potassium; but this proportion is infinitely great compared with the yield of radium from pitchblende. This ore, the only available source of radium at the present time, is only found in Austria, and as the Emperor has forbidden its export (though he has generously sent free for experimental purposes a large quantity to the curious), there has been such an enhancement of price for radium salts that the possessors of samples obtained when it was first produced commercially would now be able to re-sell as a profit of many hundreds per cent. In fact, it would be difficult to give a market price for the article; a million pounds a pound has been stated to be a current quotation, though, as we need scarcely say, a pound has never been seen or even produced. Hence considerable interest attaches to a statement that has been going the rounds of the papers lately to the effect that the Swedish chemist Landin has discovered in Sweden a large deposit of ore which is rich in uranium, from which he has already extracted radium. Landin is stated to be keeping the locality of deposit a strict secret until he shall have been able to acquire the ground and prepare the processes for the extraction of radium. Then, again, following on the discovery of uranium in many of the mining districts of Portugal, the Government intends to establish an important industry for the manufacture of radium, from which great results are hoped. A committee was recently appointed to investigate the matter and report to the Government.

A Rival to Radium.

Professor Baskerville, of the University of North Carolina, has made the announcement at a meeting of the Chemists' Club, held in New York, that he has discovered two new elements, for which he proposes the names Carolinium and Berzelium. They possess very remarkable properties, in some respects resembling those of radium. He distils thorium oxide in a quartz tube with carbon and chlorine, and thus produces a greenish, condensable vapour, to which he gives the name berzelium, of a pinkish, crystalline substance, which adheres to the quartz tube, and which he has named carolinium, and a certain quantity of thoria remains unchanged in the tube. In his lecture Professor Baskerville, the room being darkened, exhibited the two elements, and showed that each of them is capable of giving off luminous emanations which will pass through tubes of copper, brass, iron, and glass inserted within one another and covered with cloth. Further investigations are in progress, in which Professor Zerban, of Berlin, will co-operate. One account of these experiments states that the Professor has 5 grams of carolinium and 2.5 grams of berzelium in hand, while another puts down the quantity as three grains, stating that it has taken ten years to produce them, with the further somewhat gratuitous information that "their commercial worth is unknown."

Spring Photographs.

Last week we had a spell of really spring weather, and a few days hence we enter the "merry month of May." It is not necessary to remind readers that effects are to be had in the spring that are not obtainable at any other period of the year, and, therefore, the opportunity of securing them should not be lost while it lasts, and that often is but for a few days only—that is, for many subjects. Just now there is a craze for picture postcards, and professional photographers in country places, who, as a rule, at this time of the year, are not too fully occupied in the studio, will do well to consider the subject of securing pictures under spring conditions of local scenes. The most saleable pictures are, naturally, those of notable spots—such as churches, ruins, picturesque dells, and so forth. These are frequently—more particularly old buildings—almost entirely surrounded by trees which, when in full foliage, completely hide them when the photograph is taken from the best point of view. If the photographs are taken when the trees are devoid of leaves the pictures look bare and the scene barren. But if the same subject be taken when the leaves are just formed, and with the sun shining upon them, quite different pictures are obtained; the buildings are still to be seen, and the trees surrounding them have not the barren appearance they have when totally devoid of foliage. The same is the case with some glens, which, when the shrubs have put on their full summer garb, do not make such good pictures as while the foliage is still young and light in tint. Therefore many will do well to retake some of the views of the class referred to, so as to present them under the most pleasing conditions, as then they will be the most saleable. Just now the fruit trees are coming into bloom, and these make exceedingly fine pictures, as many painters have shown us, Millais' "Apple Blossoms," for example; but this class of subject seems to be much overlooked by photographers. It is true that photography will not depict these subjects in the brilliant colours of the painter, still, with orthochromatic plates and suitable colour screens, with a full blaze of sunlight, much may be accomplished, often in one's own back garden. It may be well, in connection with this subject, to mention that in all cases when photographing trees in blossom the plates employed should be backed so as to avoid halation, as halation

would completely spoil the effect, or at least very considerably mar it. In fruit-growing districts photographs, picture postcards, of some of the orchards would no doubt command a ready sale, as they would be novelties, a novelty in subject is what is largely sought after in this class of picture. Of course, the time for securing pictures of this type referred to is extremely limited, hence no time should be lost in securing them, for if the opportunity is lost now will not occur again for another year. Hence our reminder.

A Fraud on Photographers.

A subject of not a little interest to professional portraitists was brought before the last meeting of the Liverpool Branch of the Professional Photographers' Association. It was reference to the sending out of proofs not paid for. The member said he had learned from a firm who were doing work for amateurs that they were continually having proofs to finish, tone, and mount, and finished proofs to copy, and he hoped that some safeguard would be devised to put stop to that kind of thing. We have heard of this before, and remedies for it were suggested in our pages some time ago. So far as the copying of finished pictures is concerned there is no remedy; the customer has paid for them, and has the right to do as he likes with them. But if the customer who has untuned and unfixed proof sent to him has them finished and uses them it is a fraud on the photographer, morally if not legally, because these proofs which are finished are used in place of what the photographer would otherwise have to supply and be paid for. It has been a growing custom of late years with some portraitists to send quite a number of untuned prints as proofs. In former times only a couple or so were sent, whether the sending of a large number of proofs is good policy or not is an open question. It certainly is not if they are put to the use above stated. We have just mentioned that when the subject was mooted in our pages some time ago different remedies were suggested. One, we remember, was that a printed slip should be enclosed with the proofs, with intimation that if the proofs were not returned they would be charged for at the full price. This, we think, is open to the objection that if it were enforced it might give offence to some sitters. A preferable plan, we surmise, would be to write in an iron-gallic ink across the background as near the face, or, better still, impress with a rubber stamp some such words as these—"Unfixed proof." If this were done the print, if toned and fixed, would be of no use to the sitter, and no offence could be taken. If this were systematically done by all photographers it would be a remedy for one of the grievances complained of

* * *

The Exhibition of Specimens.

A fortnight ago, it will be remembered (see page 309 ante), it was pointed out that it was quite illegal for a photographer who had been paid for taking a portrait to print copies from the negative and use them as specimens, although some might possibly not be aware of this actual illegality. Some, we know, habitually, when they take a portrait which they think will make a good specimen for the showcase or shop window, use it as such, and frequently to the annoyance of the sitter. Some sitters, it is true, take it rather as a compliment if their portraits are exhibited. Others, on the contrary, who prefer privacy, look upon the thing in quite a different light, and a natural protest. Sometimes the photographer, as we know from letters we have replied to through the "Answers" column, refuses to remove the pictures from exhibition, as he considers himself within his rights because the negative itself belongs to him, and continues to show it in spite of the

tomers' protests. Many sitters may not know that the law gives them protection against this sort of annoyance, otherwise it might more often be put in force than it is. If proceedings were taken the defiant photographer would find that the costs he would have to pay were no trifle, and the law is quite clear on the point, as previous decisions in the High Courts have proved. It is not, however, so much the legal aspect of the question that we now specially call attention to, as it is to the policy of a photographer showing portraits of sitters against their wishes, however taking they may be as specimens, either as direct prints or enlargements. May well be taken for granted that the sitter will not patronise that photographer, nor will he or she commend him to her friends; indeed, some would use their influence against him, and that might have serious results, particularly in country places and in provincial towns, where so much depends upon recommendation. It is very unwise for anyone to show publicly portraits without getting the sitter's sanction. Some may object to their portraits being shown in the shop window, but not in the reception-room, and some will not object to either. But if permission is asked, whether accorded or not, no offence is done to the customer.

* * *

Photography and Science. We have received the first number of a monthly photographic publication devoted to the scientific aspects of photography. This periodical, called the "Revue des Sciences Photographiques," is published at the offices of the "Photographie," 118, Rue d'Assas, Paris, under the management of Charles Mendel and the editorship of M. G.-H. Niewenwsky. The first number contains articles by Major Gros, on "Photogrammetric Focimetry"; Dr. Lüppomer, on "The Photochemistry of Silver Iodide"; M. L. Thet, on "The Photomicrography of Difficult Objects"; F. Quennisset, on "Photographs of Borrelly's Comet"; Dr. L. Bakeland, on "The Influence of the Hygroscopic State of the Atmosphere in Making Photographic Prints." The proceedings of learned societies, etc., also receive attention. The scope of the work is one of such value to the advancement of photography, and the typography of this first number and the illustrations it contains so excellent, that we have much pleasure in sending it to Charles Mendel and G.-H. Niewenwsky our congratulations and best wishes for the success of their venture.

* * *

Reverse Emulsions Making Photographic Prints. The article in the "Revue des Sciences Photographiques" by Dr. L. Bakeland is very interesting to the photographer who wishes to know something of the difficulties the manufacturers of light-sensitive material have to contend with. Considering the elaborate precautions which have to be taken, it is surprising that paper and plates can be placed upon the market at their present low prices and yet yield a good profit on the capital involved. In the United States, as might be expected, the atmospheric difficulties are intensified by the extremes of heat and cold. The vehicle for emulsions in general use is gelatine, which is easily affected by heat or moisture. Even collodion presents difficulties due to the same causes. With gelatine your troubles begin at 77 deg. Fahr. The setting of the emulsion is affected, and with some varieties it drains off the paper. But if temperature has its own group of troubles for the manufacturer, moisture of the atmosphere brings with it other of greater intensity, and when the two are combined the effects are serious. A definite speed of drying is favourable to the manufacture of each kind of paper, and

this, as might be expected, is affected both by heat and moisture. Bromide papers are more rapid and give less vigorous results if they dry slowly, but quick drying is a condition of success in the manufacture of P.O.P. The latter, if dried slowly when the temperature is high and the air charged with moisture, gives reddish prints, which tone with difficulty, and the paper soon discolours. If P.O.P. is dried quickly at a low temperature the prints will be a purple-blue, and will tone easily. The keeping quality is also better. Another fact must also be borne in mind in coating the paper. The emulsion tends to set as soon as it comes in contact with air at a lower temperature. If the air is dry it absorbs water from the emulsion, and this process also lowers the temperature of the emulsion, and brings it much below that of the air itself. Capillary attraction also plays a part, the water being more or less rapidly absorbed by the paper according to its condition. These difficulties are best avoided by using special means for controlling the temperature and the hygrometric condition of the atmosphere.

* * *

Lines on Bromide Prints.

The irregular, fine lines which are sometimes seen on bromide prints, and which must be familiar to most photographers, are usually attributed to electrical causes. These are also referred to by Dr. Bakeland, who says it is difficult to determine if they are due to static electricity, as they are produced by friction of any sort, and only occur on the surface of the paper. This is proved by the fact that they may be removed by gentle rubbing with cotton-wool. It is known to all that pressure as well as light will produce a developable image upon silver bromide. Sparks are also emitted when paper is quickly unrolled. Dr. Bakeland hesitates to affirm which of these causes produces the effect, but he knows that the presence of a slight amount of moisture in the air of the drying-room will prevent the marks. In a factory of photographic papers the electrometer should be consulted with as much care as the thermometer and hygrometer.

* * *

Diaphragms for Three-Colour Photography.

We see in the "Revue Photographique" that Gustav Selle, whose name is well known in connection with colour photography, has taken out a patent for diaphragms of the sector pattern. The reader will understand the underlying idea by supposing the aperture of the lens diaphragm shaped like the cross section of a quarter of an orange instead of circular. The size of this sector is regulated according to the exposure which the different colours require, and it is intended to make the three exposures of equal duration. Suppose the relative exposures to be 1, 2, and 7; then a circular diaphragm may be made with three sectors of coloured medium shaped to correspond in size to the given relative exposures. As a second alternative three diaphragms may be made with sector apertures corresponding to the exposures. Or a third alternative may be used, giving full aperture for the longest exposure and sector apertures of correct size for the shorter ones. The object of the system is not only to equalise the exposures, but to use apertures of the lens corresponding to each other in quality of definition.

* * *

Galvano-Photography.

The latest idea, according to the "Photographische Mitteilungen," is that of Josef Rieder, who proposes to obtain colour photographs by electrolysis. A polished silver plate was taken and coated with silver iodide by immersing it in a solution of iodine and petroleum ether. The plate

was then exposed to light and fumed with mercury as for the daguerreotype process. After removal of the excess of silver iodide the plate was placed at the anode in the colouring bath, which consisted of a solution of lead oxide and caustic potash. When the electric current was closed colours began to appear, which were modified by altering the distance of separation between cathode and anode. Rieder thinks, as it is possible to produce colours in this way, it may also be possible to regulate their distribution, but the writer of the paragraph, who signs himself Dr. O., expresses a doubt as to its practicability.

THE COLLOTYPE PROCESS FOR POSTCARDS.

THE picture-postcard boom, although perhaps not quite so pronounced as at first, shows no real signs of abatement. Those photographers who seized their opportunity to create a fresh trade, as a welcome diversion for the slack season, are still reaping a satisfactory recompense. It is, however, rather surprising that so few workers have seen fit to adopt the colotype process as a means of reproduction, preferring in the majority of cases, when doing the work themselves, to print in bromide. It can hardly be known how really simple in operation and sure in result the colotype process proves itself once a few leading principles have been grasped. A few remarks on the subject may not be unacceptable to those who are already engaged in the production of photographic postcards or who contemplate undertaking them.

It is a settled conviction with many that an expensive press is necessary. This is by no means the case. An ordinary letter-copying press will do very good work, several patterns of printing-presses may be readily adapted, while an excellent colotype press, taking a plate $10 \times 7\frac{1}{2}$, may be obtained for about seven guineas. The drying oven for the plates, although a great advantage, is not absolutely indispensable; a very good substitute may be quickly made with a suitably perforated wooden box, provided with a metal shelf for the sand-bath, properly levelled ledges for the plates, and a couple of long atmospheric gas burners connected with a rubber tube for heating. The box is open at the top, and covered during use with a canvas lid to allow of free ventilation. The preparation of the glass plates presents little difficulty to a careful worker. Glasses of suitable size are obtainable of any dealer in photo-mechanical goods. It is advisable at first to buy them ready ground; when a little experience has been gained they may be ground as wanted by placing the finest emery powder between the glasses, well wetting with water, and rubbing them over each other till both are sufficiently ground; they are then well washed and dried. Before they can be sensitised a substratum must be applied to the glass.

A good formula is as follows:—Albumen, 5 oz.; potassium silicate, 2 oz.; water, 5 oz. This should be well mixed and filtered, and poured over the plate in much the same way as a varnish. The latter is then placed in a rack to dry; when dry it is rinsed under the tap and again dried. A suitable formula for sensitising is Creutz middle hard gelatine, 1 oz.; potassium bichromate, 50 grs.; ammonia bichromate, 30 grs.; chrome alum, 1 gr.; water, 10 oz. The water is divided into two portions, the gelatine being placed in one and the bichromates and chrome alum in the other. As soon as the gelatine has absorbed the water it is melted by a gentle heat and the bichromate solution added gradually, stirring well. The solution is then filtered through swansdown, calico, or wash-leather before it has time to get cool. For this purpose a filter pump or similar device is very useful. When filtered the

solution is ready for application to the plates, which should be first warmed. The liquid is poured on similarly to a varnish, helping it where desirable with a clean glass rod. It is now placed to dry on a perfectly level shelf or slab in a drying oven for about two hours, the most suitable temperature being about 120 deg. Fahr. Draughts and vibration should be carefully avoided during the drying. The plates should dry evenly, absolutely free from streaks, with a dull matt surface. They are then ready for exposure. A printing frame with wedges or screws is preferable, for postcard work not absolutely necessary so long as clamping pressure and contact can be ensured. The most suitable negative is one that is soft, with ample gradation of detail; hard negatives are quite useless if the best results are desired. The edges of the negative are masked by gumming on narrow strips of tinfoil to the desired shape. Printing is judged by looking at the back of the plate; a faint brown image is visible, and detail should be perceptible in the high lights. Those who prefer it may work with an actinometer after one or two preliminary experiments. Development is effected by washing with water until the bichromate is completely removed; this may take about an hour and a half to two hours. The image will be invisible, but will perhaps show a slight amount of relief. The plate is then stood up to dry. Before it can be printed from it must be treated with what is known as "the etch," a solution intended to be thoroughly damp and keep it in a moist condition. The term is a misnomer, no actual etching takes place. A good formula for this solution is water, 10 oz.; glycerine, 15 oz.; sodium chloride, 25 grs. The plate is levelled and the solution poured over, allowed to remain for from a quarter of an hour to three hours according to the hardness or softness of the plate, a factor which naturally depends on the exposure given. An overexposed plate will need to remain longer under the solution than a normally exposed one. It is better to give, say, half an hour first, then to wipe off the solution with a sponge, and gently dry the plate with a clean rag. The plate can now be placed in the press, inked, and an impression pulled, when, if unsatisfactory, the ink may be removed with turpentine and a further etch given.

An ink slab, a small quantity of thick colotype ink, a nap roller, and a composition or gelatine roller are required. For the ink slab an old lithographic stone may be used, on which the thick ink is to be worked up with a little colotype varnish and a palette knife. The stone should be used as stiff as possible, and is applied to the plate with the nap roller, a fair amount of pressure being used and the work being done rather slowly until the plate appears black all over. The latter is now rolled with a composition roller, more rapidly and with less pressure. This will clean the picture up a good deal, and several proofs can now be taken, when it will be seen whether the plate requires re-etching or other treatment. The margin may be cleaned, if necessary, with a strong solution of lime or by masking the edges with strips of oiled paper. Care must be taken that the plate is well cleaned at the back before placing in the press, as the slightest grit or inequality will cause it to crack under pressure. It must be accurately levelled, and laid on about half a dozen sheets of thick blotting-paper as a bedding. Perhaps enough has been said to show that the colotype process is by no means so difficult as many imagine. With the aid of one of the various excellent and inexpensive manuals on the subject now obtainable it should be quite possible to master the initial difficulties, with a moderate amount of perseverance in a very short time. There are, it should be mentioned, one or two even simpler modifications of colotype, in which the necessity for a glass plate is done away with: these are peculiarly adapted for postcard work, where very large

numbers of prints from one negative are not desired. The photographic worker who makes a chronic complaint of "bad business" is strongly urged to make a trial of the many possibilities of collotype, not only for postcard work, but for the numerous other purposes which will readily suggest themselves, not the least of which is the rapid completion of orders in dull weather.

RADIUM TESTING.

[Reprinted from the "Pharmaceutical Journal,"]

In testing the commercial value of radium by means of the electroscope it is important that a full knowledge of the various steps involved should be obtained. I therefore propose to consider more closely the properties of the various rays under consideration and point out the reasons for certain modes of procedure.

In the first place, it is out of the question to measure the total radiant energy, because all radium salts are sold so enclosed that about 99 per cent. of the total energy cannot escape from the containing vessel, which is usually made of glass or mica. Both of these substances cut off every trace of the gaseous radio-active emanation. The Alpha rays, too, are entirely cut off by the glass, and only the merest trace, if any, can pass through the very thin mica window of the uraninite capsules; therefore in practice we are not concerned with these two forms of emission, but are simply concerned with the Beta and Gamma rays, which, together, constitute the remaining 1 per cent. of the total radiant energy.

It is a singular fact that the therapeutic success already obtained has been the result of this 1 per cent. only; it is with this relatively small proportion that the luminous screen effects, the photographic effects, and electrical properties are demonstrated.

The electroscope does not measure the Beta and Gamma rays directly; what we measure with it is the ionisation of the air produced by these rays. In some way these rays, in passing through any gas, so agitate, or shatter, its molecules, either by simple impact of the projected negative corpuscles, or electrons, which constitute the Beta rays, or by sustained agitation resulting from the neutral Gamma rays, which are probably ethereal disturbances, that it is capable of conducting electricity. When any gas which is ordinarily a very poor conductor of electricity is ionised, it is at once a very good conductor; and so the charge on the electroscope, whether positive or negative, can leak away in proportion to the rays producing this condition. It is most important to bear in mind that ionisation, however produced, does not cease to exist instantaneously. This peculiar condition lasts for a fraction of a second—long enough for the ionised molecules to be blown a few inches.

This temporary persistence of ionisation can be well shown as a lecture experiment (see diagram) by placing a tube of radium inside a thick lead pipe, about 2 ft. long, which has been S-shaped, so that practically all the straight line radiation is cut off. If the other end of the pipe is placed near the electroscope there is no discharge, but if the mouth is placed near the end containing the radium a puff of breath through the pipe will blow the already ionised air surrounding the radium through the bent tube, and in this way the charge can be blown off the electroscope like blowing a candle out. It is as well to first blow air through when the radium is not within the pipe, to show that there is no effect without the radium.

It will now be seen that draughts in the testing-room should be avoided as much as possible, for the radio-activity readings may be higher if the air movement takes place from the speci-

men being tested towards the instrument, and it is possible for the reverse motion to give a reading which is too low. This error can be entirely eliminated by letting the distance be fairly great—it is not likely to influence the result, in any ordinary room, at the selected standard distance of 3 ft.

Red-hot bodies also have the power of producing ionisation, but this effect is only produced in their immediate vicinity. However, the air, thus rendered conducting, can be moved over a considerable distance, and so cause error. For this reason any flame should be remote, and smoking forbidden near the electroscope.

Samples should be placed on an equality as much as possible; therefore it is well to allow for differences in thickness of the glass tubes by enclosing all specimens in another receptacle, through which only penetrating rays can pass. If a tin box is used this condition is ensured, and the conditions may be regarded as uniform throughout. The lid should be placed on the box to enclose the ionised air in the immediate vicinity of the sample.

To show the reliability of this method, I may mention the result of a recent test of a glass tube of radium bromide, said to be pure, containing 10 milligrammes, for which a large sum had been paid. The electroscopic needle fell in 313 seconds with the standard specimen tube containing 5 milligrammes, but the specimen to be tested required 1,125 seconds, whereas if it had contained 10 milligrammes of pure bromide it should have discharged the instrument in half the time of the 5-milligramme tube; therefore,

$$\frac{313 \times 5}{1,125} = 1.39 \text{ milligrammes};$$

the radio-activity of the specimen was only equal to 1.39 milligrammes of pure bromide. The vendor insisted it was pure bromide, and disputed my test. This sample was then tested by Sir William Ramsay, who wrote under my certificate confirming it. His actual figures were 1.33 milligrammes.

F. H. GLEW.

SOUTHAMPTON Camera Club.—On April 25 the members of this club held the final meeting of their winter programme. Under the presidency of Mr. G. T. Vivian, a lantern slide competition was conducted. The subject was "Architecture," and the result was a tie between Messrs. W. R. Kay and S. G. Kimber, both of whom produced highly creditable specimens of architectural photography. They will both be awarded the club's certificate of merit. Mr. Kay also gains the certificate for the highest aggregate marks for the competitions of the season. An attractive summer programme has been prepared.

MESSRS. KODAK, LIMITED, have had a letter from Prince Khulkoff, Russian Minister of Ways and Communication, who personally superintended the arrangements for the temporary railway across Lake Baikal during the last six weeks, and the transport of the Russian Army en route for Harbin, for which he was responsible. He was provided with a Kodak—a No. 3 Folding Pocket Kodak—and being a photographer, made about 120 exposures of incidents in connection with the transport arrangements for his Majesty the Czar. These were sent to Kodak, Limited, at St. Petersburg, for hasty reproduction. The work was undertaken, and in less than seven hours the films were developed, fixed, washed, and dried, prints made from them, and mounted up in an album for the Czar.

FIFTY YEARS AGO.

[From the "Liverpool Photographic Journal" (now "The British Journal of Photography") of April, 1854.]

THE second meeting of the second session was held at the Royal Institution, Colquitt Street, on Tuesday evening, April 4, 1854, Mr. Corey occupying the chair.

The Chairman opened the proceedings by directing attention to an article in the "Times" of the previous Saturday, under the head of "The Preparations for War," which he said would serve to convince them of the progress their art was making, and the important functions it was likely to perform to the community at large. He then read the following paragraph:—

"Although the experiments recently made by Captain Scott on the surveying expedition to the Baltic, in taking photographic pictures of castles, forts, coast lines, and headlands were somewhat deficient in finish, they are nevertheless considered highly successful for the object in view. Some of them were executed instantaneously from the deck of a vessel going at the rate of 10 and even 11 knots per hour; though for the delicate manipulation which the process requires, he had nothing better than a sleeping berth at his command. Captain Scott exhibited his pictures at the last meeting of the council of the Photographic Society, where they excited much interest. Some Sappers are now undergoing a course of training by Mr. Thurston Thompson, with a view to the use of photography, as already announced, in the operations of the army in the East. We are also informed that several new cameras are being constructed for the more convenient application of this ingenious and beautiful art to war purposes, both by sea and land. It is proposed that the ship cameras should be suspended, like the compass, on a universal joint, with a pendulum attached, and that those for the field should run on wheels, with a strut to ensure steadiness. The mechanical difficulties in excluding light from the collodion paper used in the process have also been overcome. On shipboard a camera is focussed from the trough of the sea, as is the custom in gunnery practice."

It was little contemplated, he believed, when this process was first set on foot by the originators of the art, that it would be devoted to such a warlike purpose; it was, however, a very great comfort that all the objects they carried out were not necessarily connected with the scenes of war. He then proceeded to state that he had received a letter from their friend Mr. Newlands, who unfortunately was unable to occupy his place as chairman, which he filled with so much credit to them all. It appeared from the letter that the art had been brought to bear in the reproduction of old pictures upon wood and zinc, which could of course afterwards be engraved. He had occasion at a former meeting to call attention to some that had been done on steel; but it was not likely that that process would be practised to any great extent. He did not see why this method of reproduction and engraving, which bore an analogy to anastatic printing, should not become one of the most important branches of their art. As another instance of the progress they were making, he found a notice of what he had just been reading to them from the *Times* in the French paper *La Lumière*. The following is the article alluded to:—

"LA PHOTOGRAPHIE ET LA GUERRE.—Il est intéressant d'observer les développements de tout art nouveau et de suivre les directions inattendues qu'il prend. La photographie, par exemple, a été considérée d'abord comme une curiosité scientifique; puis elle a progressé de jour en jour, jusqu'à ce qu'elle soit devenue un instrument qui, dans la main de tous, prête son concours aux arts et à la civilisation. Elle paraît être destinée maintenant à aider aux opérations de la guerre. On annonce que le gouvernement anglais va attacher des photographes aux expéditions de terre et de mer envoyées en Orient. On

comprend l'importance d'une pareille décision, et les résultats obtenus dépasseront très-certainement de beaucoup les espérances de l'autorité. Il est inutile d'indiquer les nombreuses applications qui peuvent être faites de la photographie à pareille circonstance. Une dépêche, accompagnée de vues photographiques, donnera des renseignements bien plus précis qu'un simple document écrit, si volumineux et si détaillé qu'il puisse être. On peut, avec un objectif, reproduire instantanément des promontoires, des côtes, des forts, des dispositions des flottes, des armées, des positions militaires, et si le stéréoscope peut être employé, rien ne saurait être comparé aux résultats qu'on obtiendra.

Le procédé au collodion semble devoir être le plus convenable pour ce genre de reproductions, et si les avantages de la poudre-coton n'ont pas été reconnus suffisants pour en faire en l'appliquant aux armes à feu, un moyen de guerre, elle pourra, du moins, dans la nouvelle application que la chimie en a faite, en la dissolvant dans l'éther, servir puissamment aux opérations militaires.

"La Société photographique de Londres, avec laquelle le gouvernement s'est mis en relations, ne manquera pas de lui indiquer des artistes capables de seconder ses intentions."

"On dit que lord Raglan se propose d'avoir avec lui, en Orient, un photographe expérimenté. La Société des arts s'est prise, à ce sujet, des renseignements auprès de la Société photographique, et nous croyons que cette idée appartient à prince Albert. Tous ceux qui savent l'importance qu'ont dans une campagne les informations exactes, n'ont pas besoin qu'on leur explique la valeur qu'auraient des dessins photographiques sur divers sujets."

"Nous apprenons de source certaine qu'un photographe de Paris a été désigné pour faire partie de l'expédition d'Orient, et qu'il sera mis à la disposition de M. le maréchal Saint-Arnaud."

He would now call their attention to some beautiful photographs before them, some of which they had seen before, and many others of a similar description; and he had also the honour of having entrusted to him the introduction of M. Kastner, a gentleman then present, who had shown very remarkable talent in the execution of photographic pictures upon ivory. It was the province of this Society to foster and promote talent wherever they met with it, and as this was talent of a very extraordinary character, they should lend their best assistance to further his views. M. Kastner did not come here as an adventurer, merely seeking money, but he wished to promote science by opening a gallery here. If required to give instruction he would be happy to do so; and he wished to develop the art by producing pictures of a most superior character. He would also be happy to give gentlemen his views in private.

Some of M. Kastner's pictures were handed round. We believe that the process of taking pictures on ivory was discovered by Dr. Frank, of London.

The names of several new members were proposed by Mr. Berry, the Secretary—amongst them that of Dr. Dickinson, the President of the Literary and Philosophical Society.

The Chairman said he must call the attention of the meeting to a very important fact. The season was now getting full on; they were pledged to the public to execute something, and to stand in an honourable and elevated position at the time of the visit of the British Association to this town; and he therefore behoved every man to be up and stirring. He had placed in his hand a catalogue from Dundee, where even so early in the season they had produced five hundred and thirty-eight pictures, some of them of very first-rate character. In the preface to the catalogue there were the following remarks:—

"The admirer of Nature and of Art may be fascinated by the beauty of the landscape, or of the human figure, or of the

works of man, and try to carry away a vivid and lasting recollection of the object which so enraptured him; but his memory fails to retain the scene which was delineated for a time with the truth of nature upon the retina of his eye.

"The object of the photographer is to remedy the deficiency of memory, and so to paint and seize the passing scenes as to make their beauties undying.

"The optical glasses of the camera obscura may be likened to the crystalline lens of the eye; and the paper or plate exposed within the camera to the retina. The image falls upon the retina, but disappears. By the chemical process the image falling upon the prepared plate or paper in the focus of the camera can be fixed, and retained, and reproduced, so as to endure for ages."

He (the Chairman) rather thought that they might say that it was the anatomical knowledge of the construction of the eye that gave the first idea of the camera obscura. There were pictures described in the catalogue as "wax paper," "collodion," "calotype," "talbotype," "albumen," "albumen on glass," "iodized paper," etc. "The pictures No. 79 to 84 illustrate photo-lithography, by which it is to be understood that the picture is first delineated, by the agency of light, on a lithographic stone, and afterwards copies are printed off by the ordinary lithographic process." The Chairman then proceeded to say, that, since they last met, some of their members must have experienced failures in the experiments they have made, which failures they ought to communicate to the Society, because they met together for the improvement and advancement of the science, and it was only by exchanging ideas that they could expect to make any progress.

Mr. Bell (the Treasurer) said he should be sorry indeed to show all his failures, especially after trying Mr. Berry's process.

Mr. Burgess said that if he heard of the failures he should also like to hear of the causes. Might he ask if any gentleman had tried the last formula for gun-cotton, given by Mr. Hadow in the last number of the "London Photographic Journal."

The Chairman said if Mr. Burgess had tried experiments himself, perhaps he would favour them with the results.

Mr. Burgess replied that before he did so he should like to hear the experience of other gentlemen who might have succeeded better than he had.

Mr. Berry then read the following paper on "The Chemistry of Iodine and Bromine applicable to Photography."

It is not intended in this paper to enter into the chemical history of these bodies, but merely to detail the properties and preparation of those iodides and bromides most likely to be advantageous to our art. I had hoped to have given the details of an extended series of experiments on the solubility of these different bodies, from my own observation, in alcohol and ether; but I have been unable to devote the necessary time, owing to circumstances beyond my control. I will, therefore, as it were, point out the most promising for future research, with the few facts I have been enabled to collect.

Iodine has been used alone in collodion with some degree of success. Bromine has also been used as a means of rendering more rapid an iodide of potassium collodion, but from its volatility, I really must give my strong conviction that when the collodion film on the plate shall be dry enough for immersion in the bath, the bromine remaining must be rather homœopathic in quantity, and the effect on the plate must be something like that of the mysterious passes of the mesmerist. There are, however, combinations of iodine and bromine certainly worthy of a trial, and here let me point out the very important difference between chemical combinations and mere mixtures of chemicals. It is difficult to give such a definition of the results of chemical action as shall apply in all cases, but for our particular purpose I think the following will be

sufficient, thus:—The production of forms of matter possessed of properties entirely distinct from those of their component parts—for example, take bromine, a heavy reddish brown fluid; very volatile, and possessed of a most insufferable odour; then take potassium, a metal, lighter than water, and whose affinity for oxygen is so great that it takes fire on being placed on water. This inflammable metal, on being chemically combined with bromine, yields these white crystals without odour, without colour, without any metallic aspect, and without combustibility; in fact, can anything be more unlike than bromide of potassium and its elements? This, then, is chemical combination—now for an instance of simple mixture or solution.

These green crystals are sulphate of iron: we are accustomed to dissolve these in water, to form our developing solutions; this is a case of solution, not combination, for if we evaporate the water, we obtain green crystals of sulphate of iron unchanged. I will now give a list of these iodides and bromides which, being more or less soluble in spirit and ether, may possibly become useful as photographic preparations.

1st.—Bromides of iodine, or iodides of bromine, for it is difficult to say which is the electro-negative element. There is one, used I think by M. Claudet, as a sensitive agent for the daguerreotype, which is worthy of a trial as the sensitive for collodion; it is three equivalents, that is 234 parts by weight of bromine, and one equivalent, or 126 parts by weight of iodine; the iodine may be mixed with a small quantity of spirit, say, twice the bulk of the bromine and iodine employed, and the bromine then poured in at short intervals; it is well to do this in the open air, to avoid the pungent vapour of bromine evolved; by this means, a liquid is obtained resembling the original bromine, and a few drops to each ounce of plain collodion might be made for trial.

Potassium, bromide, and iodide are familiar to us all, so that I need not discuss them.

Sodium, bromide, and iodide—their properties are very similar to the potassium salts, the bromide is certainly more soluble in spirit.

Calcium, both iodide and bromide, are very soluble in spirit. I have always found the bromide yield a very quick and stable collodion, and rarely use anything else. I have no doubt the iodide would be found useful to those who prefer an iodised collodion.

Barium, iodide, and bromide are very soluble in spirit, and yielded me a very sensitive collodion—these are quite worthy of trial.

Magnesium—the bromide only is soluble in spirit.

Iron—the iodide, in spirit, gives a very rapid collodion with other iodides or bromides; but I fear the iron salt left in the bath would soon destroy its sensitiveness.

Zinc—the iodide and bromide have both been tried, but I know not with what success.

Tin—this metal forms double iodides with potassium, calcium, etc., and well deserves a trial; it is possible it may form a most rapid collodion.

Cadmium—the bromide has been used with success.

Gold—the ter-bromide formed by the action of bromine and water on powdered gold or gold-leaf is soluble in water. I obtained an instantaneous collodion with it, and shall try more experiments.

In conclusion. The iodides and bromides of potassium, sodium, calcium, barium, magnesium, may be prepared in a precisely similar manner to the process of making bromide of calcium, described by me in my paper upon bromine, in No. 2 of the Journal. And the iodides and bromides of zinc, tin, cadmium, also of cobalt and nickel, are prepared in the same way as iodide or bromide of iron. I would throw out the suggestion that possibly colours may be produced by using the iodides and bromides of some of the metals before mentioned,

either alone or in combination with the iodides, etc., of the alkalies or earths. Trusting that I may have suggested ideas that may be followed up with advantage by those members who may have more time for the research than I possess, I leave the subject in the hands of the Society. I shall be happy to give any further information to anyone requiring it.

The Chairman said the tendency of papers such as that they had just heard, and that Dr. Edwards favoured them with at the last meeting, was to place the Society in a very exalted position. They were no longer like men groping in the dark, in pursuit of that of which they knew little, and using chemicals with which they were comparatively unacquainted. The gentlemen to whose papers he had alluded had shown them how certain results arose, and also where errors might be avoided. Of course, though they had received the suggestions of Mr. Berry with profound attention, they would be glad to hear the experience of gentlemen who might have tried experiments with the formula that gentleman proposed. He begged to thank Mr. Berry for his very luminous paper.

Dr. Edwards said that, at the request of the Chairman, he had made a few experiments with free bromine and collodion, and his experience did not altogether bear out Mr. Berry's conclusions. He certainly thought that the addition of weak bromine, when properly added to the collodion, improved the results. A strong impression, he was aware, existed on Mr. Berry's mind, and with considerable reason, that bromine was so exceedingly volatile, even in ordinary temperatures, that there would seem to be very little chance of so small a quantity as would be used being retained by the collodion film. To prove whether that was the case or not, he added some bromine, in that preparation which was previously dissolved in spirit, to plain collodion, having no other salt present, and tried that film repeatedly, and found that with an ordinary 30-grain silver bath, he got, for at least a succession of 30 days, distinct films of bromide of silver produced. The quantity was certainly very small, and failed to give anything like a distinct impression, but still sufficient to prove to his mind that under these circumstances the collodion did retain a portion of the bromine. He was aware that certain experiments had been made which led to the conclusion that bromine precipitated the iodine from the collodion, converting it into a muddy mixture; but he thought that arose either from the bromine being added in too strong a state to the collodion, by which insoluble matter was formed, or probably a small quantity of water was put in with the bromine, for it was frequently the case that the bottles of bromine contained a stratum of water over the surface, in order to prevent the bromine from evaporating. The only way to preserve bromine was to be very careful in getting it out of the vessel which contained it. He found as a uniform result in his experience, that when collodion was made with five grains of iodide of potassium dissolved in two drachms of spirit, and one drop of bromine was dissolved in another drachm of spirit, if the iodide of potassium was mixed with collodion, and allowed thoroughly to mix first, the addition of the bromine to the collodion made a perfectly bright and yellow-coloured solution; and this collodion appeared to him to be less likely to change than any others. It was a very excellent working collodion; it was more rapid in its results, and in many respects appeared to be an improvement upon the mere iodide of potassium. It contained, as they observed, five grains of iodide of potassium, one drop of free bromine, one drachm of spirit, and five drachms of collodion, to the ounce.

The Chairman asked was not that a large proportion of spirit?

Dr. Edwards: It was a very desirable proportion; where the collodion had a good body in it, that amount of spirit was a very excellent proportion. He must say a little in favour of the presence of bromine, of which he could speak in the highest terms. It required strong baths, at least sixty grains to the

ounce, and in the winter season these baths required to be in a warm room, in order to work satisfactorily; the results with him had been certainly unexceptionable, but he had found a very large proportion of amateurs who had tried the collodion and failed, and it certainly was not quite as straightforward to get pictures from it as from the other collodion. He was not speaking from his own experience, but from the experience of scores of persons, to whom he had recommended it as a good and quick collodion, and who had never been able to make anything of it. He recommended those who had recently begun the collodion process not to be impatient to use the new formula. A person working steadily with one collodion would meet with more success than if he ran about from one formula to another. If he continued to take up every fresh idea in collodion, previous to having been perfectly initiated into the processes, he would find that his experience in making pictures would last much longer than necessary. He therefore advised amateur photographers rather to purchase their collodion than make it. It might be said they could make it a great deal cheaper than they could buy it. Granted. But how many of their pictures did they succeed with? If they got good pictures it would be an extremely cheap process; if, on the contrary, their productions were failures, they would have no reason to congratulate themselves on its economy. He now wished to ask Mr. Berry a question with regard to the iodide of iron. He must say that, in his experiments with it, he was not satisfied with the result; either as to quickness, or in regard to the collodion generally. He had never been able to depend upon iodide of iron, and he knew several persons who had been disappointed with it, although they had taken care to have the other substances in a proper state. He had found that it very soon got to and destroyed the collodion, and he had abandoned its use altogether.

The Chairman inquired whether, before Mr. Berry commenced his reply, any other member wished to make an observation.

Mr. Burgess said he had tried the experiments mentioned by Mr. Edwards, and he found that the results were nearly as that gentleman had stated. He suggested the desirability of producing a picture with the different descriptions of collodion in order that they might be enabled to judge of the relative merits of the productions, and he was understood to undertake their execution and exhibition at a future meeting.

Mr. Keith said that he was the first to recommend, at the July meeting, the use of free bromine; he had since used it almost constantly, and found it worked better than simply iodised collodion. The cloudiness complained of was perhaps caused by the precipitation of the iodide of silver, but he had always found it clear, at any rate, in a day or two. In regard to the iodide of iron, he did last summer produce instantaneous pictures with it, but he had not been able to repeat them with success.

Mr. Berry, in rising to reply, said he had to thank the meeting most cordially for the kind manner in which they had accepted his paper. With regard to the use of free bromine, he had heard from both Dr. Edwards and Mr. Keith that there really was a different action produced by its use, and of course they must take it for granted that it was so. At the same time it appeared strange to him that an agent so volatile as free bromine by being poured backwards and forwards on a plate did not diminish every time; it could not be identically the same as when the plate was first coated out of the same bottle. As to bromine precipitating the collodion and making it muddy, he never found it do so; but he had found with some collodion that even the addition of a very strong alcohol would precipitate the gun-cotton, and it required water to make it soluble again. As respected the iodide of iron, although he certainly had obtained the results which Mr. Maconochie had described, he did not think it worth the trouble of following up. He had seen

of it to a gentleman near Lancaster, and at the same time him that he expected he would obtain pictures in the fraction of a second; but he (Mr. Berry) had not found it much quicker than double iodide and bromide of ammonium. He received a letter from the gentleman, stating that he found it to be very much quicker than anything he had ever tried before; but if he worked with it more than half an hour the collodion was spoiled, and of course retarded the action very much; so that it was clear it could not be worked long with a degree of safety.

Mr. Edwards thought Mr. Berry, in his paper, had proposed, either on collodion or paper, hydrochloric acid as a sort of corrective against any free carbonate, without alkaline reaction, also as a means of preserving the bath. He thought it was possible that bromine might be there in sufficient quantity to prevent that, and preserve the state of the bath, by producing a reaction of bromine in the bath, and in that case it might have an indirect effect, by its presence as free bromine, by its being used as a corrective of alkaline reaction. He did not think at a moment that it was in the volatile state of free bromine. He thought all these substances entered into something like a chemical union. They reacted with solid salts, and, just as in a pure solution, it would be impossible to get them back in precisely the same state, or the cotton in precisely the same state, as they were previously. He thought that there was merely a union of them, but that some organic compound was formed. Hence, he thought, arose the superior sensitiveness of gun-cotton film to paper and some other substances.

Mr. Berry said that his idea quite coincided with that of Mr. Edwards, with regard to the action of materials put into collodion. It would be a rich mine of discovery to ascertain what compounds are actually formed by the reaction of the different chemicals employed after the collodion had been prepared for a considerable time.

Mr. Edwards directed attention to some photographs of the kind on which lay upon the table. The mechanical difficulties had been overcome, and they had reason to hope that the result of their labours would be successful. The best images already obtained had been converted into negatives; but those now exhibited were sufficient to show the meeting the extraordinary results obtained.

Mr. Bell said he had been requested to present, for the inspection of the Society, a series of 33 views taken on wax-paper by a friend of Mr. Carr. He thought they would all be very beautiful indeed.

The proceedings were brought to a close by the exhibition of one of Wheatstone's stereoscopic cameras, by Mr. Morecroft, whom the thanks of the Society were tendered, on the motion of Mr. Frank Howard.

We should add that Mr. Jones, who had undertaken to read a paper on "Light and Shade," was not present, and consequently the meeting was disappointed in that respect.

The Weights and Measures Bill, designed to secure greater uniformity in the administration of the law relating to weights and measures, was read a second time in the House of Commons on April 15. In moving for a second reading, Mr. Bousfield explained the provisions of the Bill, and pointed out that the fourth section of the Bill had reference to the metric system. It was proposed that after January 1, 1908, the two abnormal systems of troy weight and apothecaries' weight should be abolished in favour of the metric system. This would produce no disorganisation of trade, and would be an instalment of the reform desired, which, although a measure was now before the other House, it was unlikely that any Government would make *en bloc*, as would at first result in unpopularity. In the subsequent debate many objections were raised to this section of the Bill, and it was the understanding that the section referring to the metric system was to be withdrawn that the Bill was read a second time.

NESTS, AND HOW TO PHOTOGRAPH THEM.

So forth issu'd the seasons of the year;

First lusty Spring, all dight in leaves of flowers,

That freshly budded, and new blossoms did bear,

In which a thousand birds had built their bowers.

SPENSEE.

WITH the advent of spring comes the season of courtship amongst the birds. From every meadow, glade, and hedgerow come the rustle and flutter of wings, and the glad, joyous music of innumerable feathered songsters. Demeter, the great Earth-Mother, is sending the breath of life once more over hill and dale, through woodland and valley. As we ramble along the country lanes, at every step we take our eyes are arrested by tokens of her presence, and of the reawakening of Earth's children from their long winter sleep.

But it is more particularly with the springtime work of the birds that we are now most keenly interested. In the gray of the dawn the early pipe of half-awakened birds has set us longing to be out with camera on back, tramping through the fields and lanes once more, on a nest-photographing expedition. It is a longing which must be very promptly gratified, if we are to obtain a good series of photographs this season, for nest-building operations are in full swing, and indeed many are already completed.

Few collections of photographs are of greater interest than a good series showing the building of the nest, the nest completed and ready for the reception of the eggs, the nest containing the eggs, the mother-bird sitting, the nest with the young birds therein, and lastly the deserted nest when the young fledglings have flown. Nests are to be found in very varied situations, in bushes and trees, in holes in sandbanks and cuttings, in the hollows of trees, amongst reeds and rushes, on the ground, on rock-ledges on the face of the cliffs, and amongst the shingle high up on the sea-shore. Those nests which are built in trees and bushes, from an artistic point, are the most satisfactory to photograph. The great variety in the shape and construction of the nests themselves, and the varied environment in which they are built, offer almost endless possibilities for the production of artistic and interesting photographs. A brilliantly sunny day is by no means ideal for photographing nests, on account of the severe contrasts between light and shade, which produce an unpleasant spotty effect. A bright day with plenty of light, white clouds in the sky will enable us to obtain far better results. The greatest trouble in photographing nests built in trees and bushes is the wind, which, blowing amongst the leaves and branches, causes constant movement, and necessitates very curtailed exposures. With nests built in a fork, or amongst the small twigs at the outer end of a branch, the wind is a very serious trouble to the photographer, swaying the branch backwards and forwards, in and out of focus. If the branch is within reach, the wind trouble can be got over with the help of some stout string and a couple of wooden pegs driven into the ground. But in adopting this anchoring process care must be taken that the natural growing position of the branch is not seriously disturbed, or a very unnatural and peculiar-looking picture will be obtained. Care must also be taken in fastening back branches and leaves which obstruct the desired view of the nest. On no account should these be ruthlessly cut away; for in the first place the nest will appear with an absolutely unnatural halo of freshly cut twig ends, and secondly will permanently expose the nest to view, and, if it does not cause the parent-birds to abandon it altogether and build afresh, will endanger the lives of their offspring needlessly.

Where shadows are very heavy, a piece of white cloth and a good sized pocket mirror will be found most useful and effective reflectors.

Nests placed high up in the topmost branches of trees, like

crows' and hawks' nests, are by no means easy to photograph, and generally have to be taken from a neighbouring tree. In this class of work, a good pair of climbing irons are an absolute necessity. On no account should the photographer attempt to climb to the top of a tree with his camera strapped on his back. Let him first ascend with a cord, one end of which is attached to his camera placed on the ground under the tree, and when he has gained the vantage point from which he can obtain the best view of the nest, he can then draw his camera up by means of the cord. He will in such situations often find the cord useful to lash himself to the tree or branch, so that both hands may be free to manipulate the camera.

Photographing the nests of sea-birds, built on the ledges on the face of the cliffs, is dangerous work, calling for the greatest coolness, presence of mind, and resource in the face of unexpected difficulties, great determination, and considerable physical powers. It is one of the most dangerous branches of natural-history photography one can take up, but, like mountain-climbing, it has a charm peculiarly its own. What beautiful and interesting results can be obtained in this branch of nest-photography is fully demonstrated in the magnificent work and productions of the brothers Richard and Cherry Kearton, whose untiring perseverance and resourcefulness have won them the well-merited admiration of all true naturalist-photographers.

Nests that are built on the ground, although more accessible than those in trees and bushes, are in many respects far more difficult to make into artistic photographs. The most common fault is that the photograph is taken looking down on the nest, giving a sort of "bird's-eye view," and very little idea of the general surroundings. A very short tripod should be used, or, better still, a camp-stool, or log, or boulder; the lens must be stopped down so as to give the maximum depth of focus, and a full exposure given. A screen of cloth fastened to a couple of jointed sticks will be found useful to shelter the nest from the wind during a long exposure. When eggs are present in the nest, they must on no account be touched or their position disturbed in any way, or an unnatural photograph will be obtained. I have seen many photographs which would have been most admirable pictures rendered quite worthless on account of the photographer having rearranged the eggs.

In all nest work a lens of considerable focal length and a long-focus camera will be found most useful. The tripod should have telescopic legs, so that it can be used for bush and ground nests. The most satisfactory results will be obtained when a full exposure can be given; and, whenever possible, an orthochromatic plate should be employed. A telephoto lens forms a very valuable addition to the outfit.

F. MARTIN DUNCAN.

MR. BARAGWANATH KING, of Plymouth, who is one of the judges of the forthcoming Plymouth Photographic Exhibition, has had a very high honour paid him. On Friday last her Majesty the Queen, accompanied by Princess Victoria, paid a private visit to the exhibition of his water-colour drawings of "Scotland, from the Trossachs to Skye," at Graves' Gallery in Pall Mall. How greatly the Queen was impressed by this distinguished artist's work may be judged from the fact that in the afternoon the King himself went to inspect the drawings. Before his Majesty arrived Princess Christian also visited the Gallery. Her Majesty bought four of Mr. King's water-colour drawings. One was "The Shore, near Mallaig," a superb little sea scene of rolling clouds and deep blue water. Another is "Nightfall, Oban," with its fairy-like lights round the water and the hills. The others were "The River Lochay, at Killin," and "A White Squall off the Hebrides." In the afternoon his Majesty, who was attended by Captain Seymour Fortescue, purchased two drawings, "A Grouse Moor above Crianlarich," and "Loch Lomond from Tarbet." Mr. King is to be warmly congratulated on the Royal appreciation of his works.

SIMPLE INSTRUMENT FOR ESTIMATING RADIUM.

To make the electroscope (shown in the illustration), procure a No. 1 turned wood box and cut out the bottom, drill a hole (about $\frac{1}{2}$ in. diameter) in the side—this hole can be made with a red-hot poker without risk of splitting the wood—next, flatten the edges of box B by rubbing on sand-paper; now smear these edges with Seccotine, and clamp between two lantern-slide cover-glasses (G), a little stick sulphur in a dish or iron spoon (using as little heat as possible) and pour into a 1-drachm pill box. When set, the cardboard should be removed and the sulphur plug (S) must be trimmed taper to fit the hole in the box.

Procure a stout piece of copper wire (W), about 4 in. long, hammer flat a strip (at one end about $1\frac{1}{2}$ in. long by three-sixteenths broad), smooth this flat strip and stick on it one end of a piece of aluminium foil (A), about 1 in. long by $\frac{1}{8}$ in. broad, as shown.

It is an advantage to have one of the cover-glasses of finely-ground glass, rough side outwards (tracing-paper stuck on plain glass will do). The upper round portion of the wire must now be made hot, then pushed quickly through the sulphur plug, until about 2 in. protrudes above the stopper. The wire will quickly set in position, any adhering sulphur may then be scraped off the wire. Now adjust the stopper in position, and fix it in place with a drop of sealing wax.

The electroscope is now complete. It is best charged by means of

camel's-hair throat brush—just drawing the brush over one's coat sleeve gives the brush a positive charge of electricity—now touch the copper wire with the brush, and the aluminium leaf will be seen to stand out in proportion to the charge so given; and if the surface of the sulphur stopper is clean some charge can be retained for a day or two. Whenever the sulphur gets dirty it should be cleaned by scraping with a knife, the surface should never be touched with the fingers.

It is now necessary to graduate the ground glass by making pencil marks (No. 1 and No. 2). The instrument is now ready for use.

The graduated ground glass should be turned towards the observer, a candle, or small electric lamp, must now be placed opposite the glass window (2 or 3 yards away), so that a sharp shadow of the movable leaf is thrown on the ground glass.

Always charge the electroscope until the leaf stands slightly higher than No. 1, then note the time required for a fall from 1 to 2; this is the constant of the instrument for the particular room in which it is being used; it may take several hours, but if it falls in less than an hour there must be a considerable leak over the sulphur, or there is some radio-active material in the room, or it may be in the next room. To prove the sensitiveness of the instrument, place a Welsbach mantle about $3\frac{1}{2}$ in. from the charged wire, the leaf should then drop from 1 to 2 in about sixty seconds.

Place a 5 Mgm. glass tube of radium bromide a yard away, then charge the wire and notice the drop is too fast to be properly timed.

Therefore the sample should be slowed down by being enclosed in a metal case (a 1 lb. jujube tin is very suitable); place the radium in the tin, touching one side (raised about $\frac{1}{2}$ in. from the bottom), let it be held in place by cotton wool; put on the lid of this box and place it exactly a yard away from the electroscope, and on a level with the wire; now charge the wire as before, and if the radium is pure the drop will take place in about the same time as it did with the mantle when was $\frac{3}{4}$ in. distant.

A thorium mantle is far from being an ideal standard of radioactivity for several reasons, which cannot now be explained, besides being variable; but a very rough idea can be obtained in this way. Am trying to devise a more satisfactory standard, but, of course, the best standard is a tube of radium which is known to be pure. If a pure sample produces the drop in sixty seconds, and another sample takes 120 seconds under the same conditions, the second specimen is only half the value of the pure bromide; if it takes 180 seconds, it is only one-third the strength, and so on; it is therefore very easy to compare samples with each other with considerable accuracy. I use Geiger's preparations as standards.

The above method does not serve to measure the total radiation from radium, the Alpha rays never get through the glass. For therapeutic use, therefore, we are only concerned with the Beta and Gamma rays, both of which are thus measured indirectly by the amount of ionisation which they produce in air, and this is by far the most delicate and certain test that can be relied on.—"Pharmaceutical Journal."

MOUNTING.

THE proper mounting and trimming of a print has a very important part to play in a finished photograph. We may have made a very beautiful landscape or portrait, and if we do not mount it properly the whole effect is spoiled. Don't be afraid to trim your prints. It is much better to have a pretty little $4\frac{1}{2}$ by $3\frac{1}{4}$ than to have an $8\frac{1}{2}$ by $6\frac{1}{2}$ containing so much that there is nothing of interest because there is too much to make it so. How often we see exhibited by well-known artistic photographers little, wee pictures, and I believe we are much interested, and more, in these than we were in some of the much larger pictures shown.

Because we make a 14 by 11 negative it is no reason that the print should be of the same size. Take some of your old prints and experiment with them in this direction, and you will be surprised at the pleasing little things you will get from some of your prints that you considered worthless from a pictorial standpoint. Trim away the unimportant parts and mount properly, and your work will improve.

The selection of a proper mount is, of course, a matter which is regulated by the taste of the worker himself, very much the same as in the choosing of the composition itself, only be careful to harmonise. Don't mount a black print on a green card or a glossy purple-toned one on a light grey card. Remember that it will be safe to mount platinum and black-toned Rotox or other bromide prints on grey cards of any shade. If, however, your Rotox has not worked to a pure black tone, use a black or brownish black, or even sometimes an olive-green card. The now well-known and much-used "carbon-black" mount seems to combine all of these colours sufficiently for all general purposes, and is a very handy mount to use when in doubt.

We have all seen some very pretty prints mounted on very contrasty cards or papers; but this is very dangerous ground, and must be studied in order to learn the proper contrasts that will be acceptable. This is also true of double mounting, which consists of mounting a print on two shades, one showing but a narrow margin around the print, and this in turn being mounted on a card of a different colour or shade; but be careful, as many a good thing has been ruined by this contrasty style of mounting. The use of white mounting papers is often advisable if your print is not too hard.

In mounting prints it is, in my opinion, better to mount them wet, unless, of course, in the case of squeezed prints, and these are better mounted; or in the case of very heavy thick papers, such as Rotox and heavy platinum papers, it is only necessary to apply a little good photo paste to each corner and use strong pressure at once.

For mounting a number of regular weight prints, place them in clean water until thoroughly moistened through, then place them face down on a clean sheet of glass irregularly, so that each print will project beyond the other at some corner, and then squeegee the excess of water from the batch and apply to the top one with a flat bristle brush a

coating of a good photo paste well rubbed in, and especially see that the edges are well pasted. A small quantity of paste evenly rubbed in is better than a larger amount spread over unevenly. Then with a pin or knife blade lift up the corner of the first print and lay one side on your mount, which has been marked with a pin to show where the print is to go. Rub this edge gently with the fingers so as to make it adhere to the mount, and follow it down through the middle, rubbing lightly towards the edges. When the entire print is down on the mount, place over it a piece of clean blotter and rub over it with the hands or print roller. This is to dispel any air-bubbles that may have formed under the print. When mounted, the prints should be placed between blotters and put under pressure. If prints are to be framed, it is only necessary to "tack" to corners with paste, as the pressure of the glass will keep them smooth.—"Bromide Monthly."

Exhibitions.

CHISWICK PHOTOGRAPHIC EXHIBITION.

THE display of pictorial photographs at the Town Hall, Chiswick, (April 23, 24, and 25) was inaugurated by a very successful entertainment, which may be summarised as "supper, song, and smoke." Mr. Gentry, the exhibition secretary, is to be congratulated on securing many excellent, and not a few renowned, examples of current photographic work. Recognition is also due to him and to the Chiswick Camera Club on their successful innovation in organising competitive sets of four prints contributed by a number of photographic societies, the result being that many prints of very high quality are shown. Not that these last should be discouraged—but supplemented. Reverting to the society's exhibits, a word of commendation is due to the Capetown Photographic Society for its sea and river studies. In this class the medal was carried off by the Preston Scientific Society, among its exhibits being a curious gum print by Mr. J. Busby, which in several respects presented a superficial resemblance to some of the old engravings after Nasmyth. The Cambridge Society is awarded second honours, chief among its quartette of prints being an unusually happy realisation of a portion of the cloisters of "Queens'."

The judges, Messrs. J. A. Hodges, F.R.P.S., and W. Thomas, F.R.P.S., made the following awards:—

Club Exhibit.—Special prize of two guineas and medals: Preston Scientific and Photographic Society. No. 13, bronze medal, J. Busby; No. 14, bronze medal, A. N. Cooper; No. 15, bronze medal, W. Phillips; No. 16, bronze medal, Miss A. Marsden. Highly commended, Nottingham Camera Club, Nos. 21, 22, 23, and 24; Cambridge and District Photographic Club, Nos. 17, 18, 19, and 20.

Open Classes.—Class A.: Silver medal, No. 57, F. J. Mortimer; bronze medal, No. 60, H. Burkinshaw; bronze medal, No. 87, A. and F. Read; highly commended, No. 64, Graystone Bird. Class B.: Silver medal, no award; bronze medal, No. 97, John Spark. Class C.: Bronze medal, No. 139, A. Bedding; highly commended, No. 128, D. W. Kyle; highly commended, No. 134, E. Seymour.

Members' Classes.—Class F.: Bronze medal, No. 196, H. Hucklebridge; bronze medal, No. 214, T. A. Coys; highly commended, No. 161, T. H. Bishop; highly commended, No. 171, J. Woodger. Class G.: Bronze medal, No. 236, W. E. Walker. Class H.: Bronze medal, No. 260, J. Woodger; bronze medal, No. 267, W. E. Walker. The Club Silver Medal for the best picture in the Members' Classes was awarded to No. 185, V. G. Barford. Class D (Open).—Lantern Slides: Bronze medal (3rd set), Graystone Bird. Class J (Members).—Lantern Slides: Bronze medal, J. Woodger.

FORTHCOMING EXHIBITIONS.

May 24.—Bristol Eisteddfod. Photographic Section. Hon. Secretary, Arthur B. Cleaves, Westbury-on-Trym, Bristol.

May 11-18.—Plymouth Photographic Society. Hon. Secretary, Wilfred Grist, 105, Old Town Street, Plymouth.

May 16-28.—Photographic Society of Ireland. Hon. Secretary, E. Webb-Smith, care of Royal Dublin Society, Kildare Street, Dublin.

May 24-28.—Devonport Camera Club. Hon. Secretary, A. J. Catford, 78, Charlotte Street, Devonport.

June-October.—Glasgow Photographic Exhibition. Secretary, Art Gallery and Museum, Kelvingrove, Glasgow.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 23-26.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

New Apparatus, &c.

The "Telephoto" Cornex Hand Camera. Made by R. and J. Beck, Limited, 68, Cornhill, London.

This latest addition to the steadily growing ranks of hand cameras that the spring of each succeeding year seems to call forth, appears to strike an entirely new note in camera construction, and one that should command the attention of most serious workers on the look-out for a reliable instrument for the ensuing season. The "Telephoto" Cornex is essentially a snap-shot camera, embodying the usual attributes of a high-grade box-form magazine camera, with good lens,

shutter, finders, focussing and plate changing movements. Its chief point of novelty, however, lies in the fact that contained in the body of the camera is a telephoto attachment that by a simple movement can be brought into action at a moment's notice.

The camera is complete in itself, and by merely drawing two slides it can be changed from an ordinary snap-shot camera of the usual magazine type into a Telephoto Hand Camera, working with the same simplicity and upon the same principle. Pictures can be obtained in rapid succession, the twelve plates being charged one by one by the movement of a lever, and should it be necessary to take an ordinary photograph instead of a telephoto picture, the camera can be altered in a moment without fogging the plates in the magazine.

A further advantage that is gained in this new type of camera is a means of focussing to objects as near as 24 inches from the camera with the ordinary positive lens, without the use of any supplementary lenses, etc. The camera is supplied with three makes of positive lenses: the Beck-Steinheil Unifocal (Series I.) with an aperture of

F/4.5, the Beck-Steinheil Unifocal (Series II.) with an aperture of F/6, or the Beck Double Speed Rectilinear with an aperture of F/6. The Telephoto Lens is a negative element specially constructed to illuminate the whole of the plate and preserve, as far as possible, the perfect definition given by the positive lenses. Three finders are provided; they are of the brilliant stationary type. Two are placed in the usual positions and show the view that will be obtained with the positive alone, while in their centres is ruled a small rectangle which shows how much would be included in the picture if the Telephoto

Lens were used instead. The third finder is placed on the right-hand lower corner, and gives the view taken by the Telephoto Lens on a large scale. This "Telephoto Finder" will be found a most useful addition, and in the poorest light a bright image will be given that can be easily examined. The focussing scales are both provided with a "Cornex" Index, by means of which, not only is the focus set, but the depth of focus of the lens is given for each aperture in use. This feature is no less useful for telephotography than for general work.

New Mounts made by Charles Tyler and England Bros., Limited, 79, Copenhagen Street, London, N.

We have had submitted to us several new lines in photographic mounts made by Messrs. Tyler and England Bros. They are made in a great variety of colours and designs, and embody the latest ideas in this essential department of the professional photographers' equipment.

Many of the designs should also appeal strongly to the amateur, and not the least item in their favour is the fact that the mounts are all of English manufacture, made at the firm's own factory. The Florentine and Devon mounts, here illustrated, are particularly neat, and should command a ready sale.

Patent News.

The following applications for patents were made between April 11 and April 16, 1904:—

Printing machines.—No. 8,474. "Improvements in automatic continuous photographic printing machines." Herbert Richard Watts.
Cameras.—No. 8,766. "Improvements in and relating to photographic cameras." John Laing Kinloch and Andrew Duncan Kinloch.

Coe Collotype Company, Limited.—The above-named company has been registered with a capital of £30,000 in £1 shares (10,000 Six per Cent. Cumulative Preference). Object to acquire (1) the business carried on by A. Coe, at Vicar Lane Bradford, as the Coe Collotype Printing Company, and (2) the photographic business carried on by the said A. Coe, at Barkerend Road, Bradford, aforesaid, to adopt an agreement with the said A. Coe and J. Maddocks for the acquisition of certain rights relating to improvements in collotype machinery, and to carry on the business of collotype, letter-press, and general printers, lithographers, machine makers, paper manufacturers and merchants, dealers in photographic and collotype printers' materials and requisites, etc. No initial public issue. The first directors (to number not less than two nor more than five) are J. Maddocks (permanent chairman), special qualification, £500; A. Coe, managing director; and H. B. Booth. Ordinary qualification, £100. Remuneration (except managing directors) as fixed by the company; chairman to receive an additional £100 per annum. Registered office, 44, Vicar Lane, Bradford.

New Books.

Enzyklopädie der Photographie. Vol. 48. Das Arbeiten mit Rollfilmen, by Hugo Meyer. Verlag von Wilhelm Knapp, Halle a. S. This small volume of about 60 pages is devoted to instruction in the manipulation of rollable film, and will be found very useful by those who prefer this variety of sensitive material for camera work. There is much information in the book concerning the peculiarities of films those who wish to be *au fait* upon the subject would do well to read it. Numerous illustrations elucidate the text, and we have no doubt they will be found very useful by the amateur as a guide to correct work.

Martin's Up-to-Date Tables. Compiled and written by Alfred J. Martin, F.S.I. 255 pp. Price 2s. 6d. London: Published by T. Fisher Unwin, 11, Paternoster Buildings, E.C.

This useful little compilation of weights, measures, and coinage of the world should prove a remarkably handy desk companion. Its most obvious mission, however, is to bring home to the minds of the uninitiated the multifold advantages likely to accrue from a universal adoption of the metric system, and it states the case very clearly indeed. Practically every page contains useful information, some of which may prove of help to the photographer struggling amid the intricacies attendant on the conversion of foreign units into English denominations. Many good suggestions are given for the means whereby the metric system could be adapted to England.

It is pointed out that many British advocates of the system have met failure in the past by trying to compulsorily introduce with system its "nomenclature" en bloc, and some even insist on high pronunciation and spelling.

The author maintains, however, that if the system is to "catch on" with the British people, it is of no use telling them that in time they must buy their goods by the metre, gramme, and decitre. That is the wrong way of putting it.

We should endeavour to bring the common weights and measures of every-day life into line with the metric weights and measures, and on all our adjusted measures stamp the familiar names, prefixed the word "metric," alongside the metric value. Thus 1 metric pound, $\frac{1}{2}$ kilogram, 1 bi-pound, 1 kilogram.

In this way, Germany, Holland, and other countries adjusted their trading standards to the metric standards, and avoided French measures. Thus in Germany the meter was called the stab, the centimetre became the new zoll, the millimetre the strich, the liter the ltr., the half-liter the schoppen, and half-kilo the pfund.

A penny supplement for beginners is also published, and should be very useful in schools. It is a very comprehensive little table.

New Editions of "Photography for All," by W. Jerome Harrison, F.S., and "Practical Slide Making," by G. T. Harris, F.R.P.S., to hand. They are Nos. 1 and 2, respectively, of "Photography," a bookshelf Series, and are published at 1s. each. They are essentially working guides, and the new editions are strongly and neatly bound, as is to withstand workroom usage.

REFERRING to one of our "Answers to Correspondents" in the last issue of the BRITISH JOURNAL OF PHOTOGRAPHY re "Paraffin Casks," a respondent says:—"The simplest method of getting rid of last traces of the paraffin is to burn, i.e., set on fire a wisp of straw or paper in the cask and let it ignite the spirit in the interior. The slight charring of the wood greatly improves it as a water cask. This method is preferable to the soda washing you recommend."

ENTRIES for the Plymouth Photographic Society's eighth exhibition close on May 2, and the show promises to be a good one. In addition to the usual silver and bronze medals offered in the five open and six members' classes, a silver cup is offered in the open classes to the exhibitor whose work represented in not less than three classes will be judged of the highest merit, and a silver plaque is offered to the members' classes under like conditions. The hon. secretary is W. W. Grist, and his address is 105, Old Town Street, Plymouth. The judges are Messrs. P. H. Emerson, Baragwanath King, and F. Selley; and the exhibition will be opened by the Mayor of Plymouth on Wednesday, May 11.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
30..... May	Bowes Pk. and District Ph. Soc.	Outing. Loughton, Epping Forest.
2.....	South London Photo. Society...	{ Elementary Chemistry for Photo- graphers. Mr. C. F. Townsend. Gum-Bichromate Printing. Mr. J. C. S.
3.....	Royal Photographic Society.....	Mummery.
3.....	Nelson Photographic Society.....	Members' Negative Evening.
3.....	Rotherham Photo. Society	Ozotype. Mr. T. Manly.
3.....	Glasgow Southern Photo. Assoc.	Amateur Photographer Prize Slides.
3.....	Everton Camera Club	Make Haste Slowly. Mr. G. H. Usher.
4.....	North Middlesex Photo. Soc.	Lantern Slide and Print Competitions.
5.....	Dundee & E. of Scotland P.A.A.	Japanese Coloured Slides. [Mr. H. Drummond.
5.....	Camera Club.....	Members' Exhibition.
5.....	Watford Camera Club	Competition "Wind," "Rain," or "After Rain."
5.....	Hull Photographic Society.....	General Meeting.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION

APRIL 21, Mr. W. A. Sims in the chair. The hon. recorder showed results of exposures made upon Barnet Lustra Matt bromide paper, samples distributed a week or two ago, and thought it a very fine paper. The slides sent in by the members to the affiliation competition having been returned broken, the hon. secretary was asked to communicate with the affiliation secretary on the subject. Mr. Brown exhibited an ingenious and useful cover for a candle, for use in changing plates on tour. It was a cone made of red fabric, 12 in. high, 3 in. at base, and half an inch at top. Mr. Teape and other members were curious to know why a light at all was required for plate changing, and Mr. Becket described his plan, which is to place the ordinary chamber candlestick, with candle alight, on the floor in a corner of the room, hang his coat over a chair or two in front of the candle, then proceed to manipulate his plates at the other end of the room. A friend of his had tested the method and given an exposure of ten minutes, and failed to get fog. Watson's Antinous shutter release for roller blind and iris shutters was exhibited, and considered a great improvement upon the indiarubber release. Watson's Everset shutter was also exhibited and admired. Mr. Wright exhibited a telescopic walking stand, light and effective, made of aluminium, and which could be repaired in case of damage.

CAMERA CLUB

UNDER the modest title of "Pictures from Birdland," Mr. Oliver G. Pike last week gave a lecture upon his methods of work, and although he had not to face any terrible beasts like the whale which gave free lodging to the prophet Jonah, he has certainly been exposed to dangers which few men would care to face in order to secure a photograph or two. And let us at once say that Mr. Pike's pictures are of the best, although so many of them were taken under strange conditions and under most uncomfortable circumstances. Exposure and lighting were in most cases good, and there was an artistic quality about many of them which at once showed that their producer had an eye for pictorial effect.

The Chairman, an enthusiastic member of the Bird Society, whose name we failed to catch, gave an interesting preface to the lecture, pointing out how the old method of studying ornithology generally consisted in shooting the bird first and then stuffing it. He was loud in his denunciation of "collectors," who are mostly ignorant men who, with the collecting mania upon them, destroyed every specimen they came across, either to add to their own store, or for purposes of exchange—very often to sell. He also spoke of the danger of that "nature study" which is now so much encouraged in our schools, because it is so apt to degenerate into slaughter for collection. Birds' eggs, butterflies, and moths were destroyed by the thousand by these enterprising youngsters. It is much better to study the living thing than its corpse, and every right-thinking person would prefer the harmless camera to the gun. The society to which he belonged had recently sought permission from the Admiralty to instruct coastguards to act as watchers on behalf of the Bird Acts, and he hoped that much unnecessary cruelty would be thereby avoided.

The lecturer commenced by saying that many people thought that

bird photography was an easy thing, but he would advise any one who thought so to try and stalk a rook or a sparrow, and note how near they could get to their quarry. It required much patience and experience, but when the knowledge was once acquired the work was most exciting and fascinating. He used a reflex camera of his own design, with a lens which would split up into its components and five different foci. The first examples he showed he took at Southport—which, by the way, does not lie south and is not a port. These consisted of a number of studies of gulls, some crowded on the sands, many flying, and others tossing about on a rough sea. But he reminded his hearers that it was not necessary to go to the sea for seagulls, for they could be seen in the colder months all along the Thames Embankment in the heart of busy London. One photograph he showed taken from the Embankment in the 300th part of a second on a very dull day.

But Mr. Pike has gone further afield than this; indeed, he has roamed the country over in search of the rarer kinds of feathered bipeds, and has generally succeeded in finding them. It is not every man who would care to hang by a rope over a cliff edge for an hour so that he might secure the photograph of a raven's nest, or consent to be lowered down the steep face of the Bass Rock so that he could visit the homes of gannets there on a like errand. Nor would it suit many of us to creep along the thin branch of a tree so that our camera lens could look down for a few seconds on a nest of eggs which could not be viewed from any other position. At great pains and risks he had been able to photograph the nest of that rare bird the kite—for a single clutch of whose eggs the collector is glad to put down the sum of £10.

Many birds have been made by Mr. Pike to take their own photographs. He arranges a tempting bait on a twig near their haunts, and in connection with it is an electric device which throws the shutter of the camera into action. Directly the bird pecks at the food the shutter is released and the picture is taken. It would occupy too much of our space to give even a list of the birds whose pictures Mr. Pike has secured, not the least interesting of which was the series with which he brought his remarks to a close. First a common hen's egg. In the second picture the egg was seen with a tiny hole chipped at the side by the imprisoned chick within it. The third picture showed how the little creature had succeeded in getting one leg out, and in the fourth he was seen lying down exhausted, a moist mass beside the empty shell. The last picture showed him twelve hours afterwards, standing by the shell and wondering what it was. Mr. Pike received a hearty vote of thanks for his excellent and entertaining lecture.

CROYDON SCIENTIFIC SOCIETY.

APRIL 22.—Mr. C. A. Franklyn attended to exhibit and explain his new patent tripod camera stand. The stand differed entirely from any other on the market. Three points stood out prominently, i.e., (1) the head of the tripod was in three pieces instead of one, as is usual, each piece being attached to one of the legs, they could all be brought together and fixed centrally by the ordinary camera screw. (2) The leg had two sliding joints instead of the usual one. (3) The entire stand could be carried about easily without the usual leather straps. It will be at once seen that the tripartite revolving head affords an almost infinite variety of movement; as a matter of fact, the camera can be used by its means in a horizontal position, and through any angle from that to the lens pointing straight down, or straight up, as may be required; hence for copying by the vertical method, or for taking the ceilings of buildings, nothing could be better. Again, the legs, either or all, can be shortened from 5 ft. 3 in. to under 24 in., uneven surfaces, therefore, present no difficulties; moreover, in doing this the camera can be maintained in a perfectly horizontal position the whole time. When it is added that the stand can be used, if necessary, close against a wall, it will be apparent that it ought to command a ready sale and have a future before it. On Tuesday evening, before a crowded audience, some 150 Swiss views, taken by Mr. C. L. Faunthorpe, the late secretary to the photographic section, were shown on the screen. These were much admired; indeed, some of those portraying the Alpine peaks, with their snow-clad summits and glaciers, and numerous waterfalls, were exceptionally good.

News and Notes.

THE Traill Taylor Memorial.—A meeting of the Committee will be held at the rooms of the Royal Photographic Society, 66, Russell Square, on Tuesday evening next, May 3. The chair will be taken at 7 p.m. Agenda: The balance-sheet for the year. Election of committee members. Election of Secretary. Selection of Lecturer, &c. **SOUTHEAST Photographic Society.**—On April 22 a lecture was given before the members of this Society on "Marine Photography," by the author, Mr. F. J. Mortimer, treated his subject in a popular manner and the slides accompanying the lecture fully illustrated the points wished to bring out.

A SECOND edition of "Hand Camera Photography," by W. Kilbey, is to hand. It is elementary in character, but sound in principle, and although addressed more particularly to the beginner who elects to start in photography with a hand camera, it contains many useful hints that may be taken advantage of by the more advanced worker.

THE Technological and Scientific Dictionary is the latest edition of the many good reference books published by George Newnes, Ltd., Southampton Street, W.C. Part 1 is just issued, and the work will be completed in about fifteen monthly numbers. It will appeal to the teacher, the artist, the professional man, the trained mechanic, the student. Photography, needless to say, has its full share of attention.

An Empress's Vanity.—The "Standard's" correspondent, writing from Tien-Tsin, under date April 20, says:—"A special light railway has been constructed from the Wai-wu-pu to the station in Peking, in order that mere coolies may not have to handle the portrait of the Empress-Dowager, which she is sending to the Louis Exhibition. The painting leaves the Capital to-morrow in a special car. The expenses connected with it and its journey are already fabulous."

THE Royal Photographic Society of Great Britain.—The fifth of a series of practical demonstrations of printing processes will be given at 66, Russell Square on Tuesday, May 3rd, 1904, at 8 p.m. by Mr. J. C. S. Mummery, the subject being "Gum Bichromatic Printing." Synopsis: Brief historical notes on the process, description of the materials, tools, printing and manipulation, demonstration of the preparation of the pigment, coating the paper, washing up, image, etc.

SOUTH London Photographic Society.—Eighteen members of the society journeyed to Bexley for North Cray on April 23, and by the courtesy of a local landowner were permitted to photograph in and about some water meadows and along the banks of the River Cray, a good number of the architectural-minded made for the church, and spent the afternoon in securing records of some very fine carvings about the altar and choir stalls—some of which is believed to date back to the sixteenth century. The carved oak pulpit is dated 1616. Orthochromatic workers should note that hanging on the church wall is an oil painting of the Crucifixion by Gessi—formerly in Lamport Church—of which the vicar states he has never yet seen a satisfactory photograph.

Röntgen Society.—Ordinary general meeting, Thursday, May 1904, at 20, Hanover Square, the chair will be taken at 8.30 p.m. by Mr. J. J. Vezev, hon. treasurer, will read a paper: "The Röntgen Society; its Past Work and Future Prospects." Mr. F. H. Glew will give a short account of "Some Experiments with Alpha Rays." The epidiascope will be in use, and it is hoped that members will take the opportunity of showing slides or pictures. Medical members are invited to a meeting of the medical section, to be held in the Society's room at 19, Hanover Square, at 5.30 p.m. on the same day.—May 5th—to hear a paper on "Three Years' X-ray Work," by Dr. L. Herschell Harris, of Sydney, N.S.W. Future arrangements: June 2, Dr. Clarence A. Wright, a paper—"Experiments to Determine the Effects of Form and Winding upon Resonance Phenomena." July 7, annual general meeting. Library: The Council have arranged that the library of the Society at 19, Hanover Square, shall be open to members, for reference, every Thursday afternoon from 5 p.m. to 7 p.m., commencing on Thursday, March 3. Members are invited to send to the librarian any contributions of interest—books, journals, skiagrams, tubes, etc., etc.

Our Modern Knight-Errant.—The war correspondent is the modern

ivalent of the knight-errant. He is a free-lance in a sense less row than that in which the word is used by Mr. Clement Scott, the bonds of red tape and duty that hinder the movements of the st adventurous subaltern have no power over him. Happy is the of this twentieth-century condottiere! He writes for a public that es far less for elaborate explanations of tactics than for gaudy criptions of action; he need not worry himself about the niceties of le, for who would be so brutal as to expect anyone who writes as he es—or perhaps when he is actually under fire—to produce faultless English? He is welcome in almost every place, and he enters by alth the places that do not welcome him, and makes articles for a timony against them. He rides, he is lost on mountains, he is assassinated, he is triumphant against fearful odds. He knows all the enities of life, and supps with Crown Princes, and makes speeches en he returns to England. For this delightful existence no qualifi- ons are necessary, except, of course, courage, endurance, the know- ge of tongues, the knowledge of men, tact, good temper, and a ficient allowance of health and muscle. The metier is open to any- ; we could all be splendid war correspondents if we wished.—*World.*

EASTMAN Kodak Company of New Jersey.—The balance sheet of s company has just been issued for the year ending December 31, 03. The result of the year's working, after charging liberal ounts for depreciation, shows a net profit of £603,235 5s. 10d., king, with the sum of £96,700 17s. 9d. brought forward, a total ilable balance of £699,936 3s. 7d. After paying dividends at the e of 6 per cent. upon the Preference, and 10 per cent. upon the mmon stock, and making further special reserves of £16,165 16s. 2d., e remains a surplus to be carried forward of £222,891 6s. 8d. ention is called to the fact that the company is paying dividends on a large amount of capital which has been paid in by share- ders, but has not yet been invested; the total of railway bonds, l loans and cash, less current liabilities, amounting to £326,541. en this surplus capital is fully employed the total profits should ery considerably increased. The balance sheet discloses a very on financial position, the goodwill apparently being about 4½ ars' purchase, which will compare favourably with most indus- undertakings. In spite of depressed trade and the bad weather ast year, the business, from a comparison of the profits with those previous periods, is evidently steadily progressing.

The Camera in the Desert.—Sir Benjamin Stone, after a month's ence in Algeria, has brought back with him a collection of rare otographs. Making Tunis his headquarters, he arranged a series xpeditions, hunting out unheard-of tribes, and photographing them ividually and in groups. The 300 plates which he used will not be eloped until about three weeks' hence, although Sir Benjamin ploys two men continually on this kind of work. "If they turn ell," said Sir Benjamin to an "Express" representative, the other y, "the plates will be the best thing of the kind that anyone has e as regards Algeria. I spent several weeks there, and probably elled between three and four thousand miles, through gorges and er mountains, going among the tribes, and securing pictures that one has heretofore succeeded in getting. The difficulty among the ives was that their religion Mahometanism—prohibits them from king pictures of any natural object. Consequently, they do not like ing photographed, and it was hard work to persuade them to let 'take' them. What I did was to win over their head men, for ne of their chieftains tells them to do a thing they obey orders." Benjamin bears testimony to the safety of touring in Algeria. e French, he said, have inspired the natives with a respect for ite men, and he had no unpleasant incidents during his trip.

INDECENT Picture Post-Cards.—Amelia Praag, of 101, Caledonian ad, N., was summoned before Mr. Bros. at the Clerkenwell Police- rt, for exposing for sale indecent picture post-cards. Mr. Muskett oscuted. The defendant keeps a newsagent's shop, and on March 30 b-Divisional Inspector Briggs noticed a number of pictorial post- ds in the window. These were, according to Mr. Muskett, of a isky" character. The officer purchased half-a-dozen of the cards, d subsequently seized 1,173 other cards. He spoke to the defendant, d she expressed the opinion that the cards were indecent. In- spector Briggs, in the course of his evidence, said his attention was awn to the shop by seeing a number of young persons looking in e window. About 100 of the cards were exposed to view. He

spoke to the defendant, who said that when she purchased them she was told that she could exhibit them. He then bought seven for 11d., and on April 2 he executed a search warrant. The de- fendant rendered him every assistance in making the seizure. Mr. Bros, having examined specimens, told the defendant that she must exercise some discretion herself in purchasing picture cards. He would have thought that she would have seen that those of which the police had taken possession of were not of a proper character. Under the circumstances, he bound her over to come up for judgment if called upon, directed her to pay 6s. costs., and ordered the destruc- tion of the cards.

Work of the Optical Society.—The work of the Optical Society was passed under review by Dr. R. T. Glazebrook, the president, at a meeting held last week at 20, Hanover Square. There could be no doubt, he said, that in recent years the rate of progress of the optical industry in foreign countries had been greater than in England. The fact of German success was continually paraded before them. The cause did not lie in the greater skill or ingenuity of the German work- man—British honesty, doggedness, and pluck were still effective assets on our side—but in the fact that elsewhere the value of science as a commercial factor was more fully realised than with us. The work of the Optical Society was carried out largely by co-operation; it consisted of some two hundred and twenty members, practically all closely connected with optical work, and already there was a wiser feeling recognised in the trade. Efforts were being made to organise a Convention of Opticians, and he thought that a representative exhibition of English instruments, arranged to show the best that they could do, would be of distinct service to the industry. The society had realised the importance of education, and in co-operation with the Northampton Institute had taken steps of real moment. At a fitting time the new education authority for London must be reminded of the urgent need for a larger and more complete organisation. Respecting standardisation the society had not been amiss. When it was once realised that the trade required standardisation it must come, and he should esteem it a privilege to work with the society to secure it.

We regret to see the announcement of the death of Sir Henry Thompson, distinguished as a surgeon and by his active interest in many departments of science. Sir Henry Thompson was born at Framlingham, Suffolk, on August 6, 1820, and received his early education at University College, London. He gained the Jacksonian prize of the Royal College of Surgeons in 1852 and 1860 for essays on surgical subjects. In 1866 he was appointed Professor of Clinical Surgery in University College Hospital; and in 1884 he became Professor of Pathology and Surgery to the Royal College of Surgeons. He took a leading part in the establishment of cremation in this country as a proper method of disposal of the dead, and was president of the Cremation Society from its foundation in 1874. He was the author of numerous works, including volumes and papers on the branches of surgery in which he was an acknowledged master, on motor cars, horses, diet, and death certification, and also of two novels. For several years he cultivated astronomical studies, and had a well equipped observatory constructed at Molesey, but this was abandoned after a time, and the two fine refractors were presented to the Royal Observatory, Greenwich. Later, in 1897, Sir Henry Thompson added to his gift the thirty inch photographic reflector which bears his name. He was knighted in 1867 and created a Baronet in 1899, and was the recipient of many honours and distinctions from professional and other learned societies, both at home and abroad.

CINEMATOPHGRHS in the Street.—At Lambeth Police-court on Tues- day last, Frank Lloyd, 32, described as a steward, and Arthur James Porter, 24, a photographer, surrendered to their bail, and were charged on remand before Mr. Hopkins with causing an obstruction by causing a crowd to assemble. On the afternoon of the 12th inst. Police-inspector McCarthy found a large crowd assembled in Cramp- ton Street, Newington, and upon investigating the case, found Porter standing in the centre of the roadway, with a cinematograph machine. A tableau had been arranged on the pavement, in which Lloyd, attired as a police-sergeant, appeared to be the leading character. In view of the obstruction which was caused, Inspector McCarthy arrested Lloyd and Porter, who were brought before the Magistrate, and remanded on bail, in order that summonses might be issued against the other defendants. Inspector McCarthy now informed his Wor- ship that Mr. Collins was present at the time the picture was being taken, and was stage-manager of the affair; Mr. Bromhead was the

manager of a cinematograph company, and was responsible for sending the other men out to take pictures in the streets. Mr. Collins pointed out to the Magistrate that the taking of the picture only occupied a few seconds. Mr. Hopkins said he did not see how this sort of thing could be done in the London streets. Mr. Bromhead: We have done it often with the co-operation of the Magistrates in many cases. At Worthing and other places the J.P.'s have assisted us. Mr. Hopkins: I am afraid you will find London too big. Mr. Bromhead: We are far from wishing to cause an obstruction. If the inspector had cautioned the men they would have gone away. I admit that it was a great mistake to take a picture at that time of the day. I have taken pictures myself in the neighbourhood with an inspector present. Mr. Hopkins: Here, you see, you have got a sort of play going on, with a sham sergeant of your own. I don't see how it can possibly be done in the London streets. Mr. Bromhead: We are only too anxious not to cause an obstruction; we certainly do not cause such a large crowd as the Salvation Army, and we never occupy the street more than a few minutes. Mr. Hopkins: You see what this is coming to. The next thing we shall have will be a motor accident in Piccadilly for the purpose of being taken on the cinematograph, and brought out at the Empire the same evening. Plainly, it can't be done in London. Mr. Bromhead and Mr. Collins were each ordered to pay a nominal penalty of 10s. and 2s. costs. Lloyd and Porter were discharged.

A CORRESPONDENT in the "English Mechanic" describes a method of producing home-made gas for illuminating and laboratory purposes, which is interesting. He says:—"When living in the country miles away from any public gasworks, it is a great boon to be able to manufacture your own gas in a simple way to light your workshop and laboratory, and also for various heating purposes for which gas alone is satisfactory. For Bunsen burners, incubators, blowpipe work, heating soldering irons, and also for illuminating purposes, it is almost indispensable. For years I have made my own, and as I have always found it very satisfactory, I think other amateurs may like to make a similar apparatus. The gas is made by forcing air through gasoline, which is a highly volatile fluid of the nature of benzoline; the air becomes saturated with its vapour so as to burn like ordinary coal-gas. It is necessary to have a generator and a blower. The generator is one of Fletcher's, and consists of a tin box filled with wicks which dip into the gasoline, which is poured into the generator until it is about one-third full. Of course, this has been made for many years, and is usually used with foot-bellows for furnace and blowpipe work; but for a constant gas supply some simpler blower is required. I have tried several. First I had a gasometer, which I filled with air by pulling it up, and then, as it sank in the water, it forced the air through the generator. The objection to this was, that you had to pull it up every time, and, also, unless you had a very large gasometer it did not last any time. Next, I made a sort of revolving drum, on the principle of a gas-meter, which was worked by a falling weight, and as it revolved in water it carried a constant pressure of air. This was not very satisfactory. It had a habit of going unevenly, would sometimes stop altogether, or suddenly run down at a great speed. The blower I use now is a very simple affair and works very evenly. It consists of two tin cans, one inverted inside the other. The inner can is about 4 in. in diameter, and about the same depth. Through the bottom is inserted and soldered in a piece of 1 in. pipe, open at both ends. There is also a small pipe soldered to the bottom for the exit air. The outer can is open at the top, and is rather bigger in diameter, and about three-quarters the height of the inner can. An overflow pipe is soldered to this with a movable elbow, so that the height of the water in it can be varied. A cork is fitted with a fine brass or glass nozzle, and inserted in the water-supply tap. The stream of water issuing from the nozzle passes into the tin pipe, and into the water contained in the outer tin, carrying with it a quantity of air bubbles, which rise to the surface, and become imprisoned in the inner can, thus giving a constant pressure of air, which can be varied by raising or lowering the overflow pipe. The air is conducted by an indiarubber pipe to the generator, and issues as gas. It is necessary to put a weight of some sort on the upper can, or the pressure of air will lift it up. The lower portion of this can should be notched to allow the water to flow freely into the outer can. With this smaller apparatus I can keep three gaslights burning, and a Bunsen at the same time.

PHOTOGRAPHY FOR BABES.

To the Editors.

Gentlemen,—My attention has just been directed to your paragraph (page 307, April 15) "Photography for Babies."

As I am indirectly responsible for the method proposed for removing the images of spoilt prints, perhaps you will permit me to say that the editors of the leading London daily papers do not encourage verbal attacks and they would be extremely likely to use their blue pencil in order to strike out obvious "padding." When speaking to photographers (even "baby" photographers) it is hardly necessary to waste a lot of valuable space in offering precautions as to the use of poisons, any daily paper editor would be justified in considering such caution as "padding." Surely you are quite aware that no one—he "be" a photographer or otherwise—is able to buy potassium cyanide at a sweetstuff shop, but has to go to a properly qualified chemist; he has to sign the poison book, and be properly identified before he receives the poison. Under these conditions, it is not likely that he would take it as a beverage; nor is it likely that a photographer (even a "baby" photographer) would be likely to employ a tea-tray for photographic purposes. Even if he did so employ a tea-tray, I do not think the ultimate result would be very tragic; but surely you would not expect a writer to devote several lines to describing exactly what sort of a tray must be used for photographic purposes?

In your attempt to set the advertisers against the writer, you appear to overlook the fact that you are treating amateur photographers (even "babes") as altogether devoid of ordinary understanding. As a matter of fact, the matter in the paragraph to which you refer was suggested by an inquiry from a man who wished to utilise his spoilt prints, and particularly specified the way in which he wished to use them.—Yours faithfully,

April 22, 1904.

To the Editors.

Gentlemen,—In "Ex Cathedra" of yours of the 15th inst., under the heading "Photography for Babies," you hit hard, and rightly so, one of our dailies for an article on bleaching wasters with cyanide. Everything you said there was true, but if it is true in a non-fessional journal, what can one think of the same appearing, word for word, I think (I have not seen the article on the daily) in a journal devoted to photography? Please see (I expect, though, you have already) page 323 of the "Amateur Photographer" for April 21, and let us know whether you think it right for a paper which knows the dangers of cyanides to recommend its use without any warning, as is evident the asker of the question can't know much about it.—Yours truly,

April 24, 1904.

REPRESSION OF THE BRITISH INVENTOR.

To the Editors.

Gentlemen,—An extract is given by you in the issue of March from the "Journal of the Society of Arts." Therein is compared the difference between inventor and author, their treatment as regards patent and copyright, and an apparent injustice to the patentee. The writer does not seem to have noticed that the public and not the inventor are being considered. The work of the inventor is looked upon as of greater need for public use than that of the author; therefore a comparatively short term (fourteen years!) is supposed to recompense the inventor, so that the public may the sooner have the benefit of free use. It should be noticed, also, that in practice the right works cheaper with time, and after a few years are supplied to the public, through the publisher, at quite nominal royalties.

There seems to me no comparison between a book and an invention. Our patent system at present is hard, expensive, and inadequate; it is on a different standing to copyright. It is an infinitely more difficult matter to deal with. It is much more easy to grumble.

are too high. Make them lower and multiply the number of useless, invalid, or unworkable patents. Refuse to grant a patent as it is for an original or valuable matter. Who is to decide? Patent Office?

No doubt something can be done, and I hope will be done in the future; but it is a difficult matter to inaugurate a system that not work hardly on some one.

Imagine a committee of experts, the highest in the land, to decide every invention as the patent is applied for, to decide for once and whether such patent shall be granted or no, and if granted to hold hold question or possibility of contestation. Such a system would, doubtless, be perfect, but for one little matter—the enormous number of patents applied for, and the time required to thoroughly sift the details and evidence as to novelty, etc. A big patent case in the Courts runs into weeks. Could all this time, labour, expert thought, and decision, be given to every Tom, Dick, or Harry who wanted to patent a new print-washer? And I don't think it could be for five shillings!

An intermediate course, certain searches by the Patent Office officials, will, doubtless, be adopted—in time! I am, yours faithfully,
C. HAROLD SMITH.

1, Avenue Road, Fordsburg, Johannesburg,
April 4, 1904.

TO PROSPECTIVE PATENTEES.

To the Editors.

Gentlemen, Patents and fortunes are not exactly synonymous. But many patents are being taken out nowadays that one cannot help wondering if many of these inventors do think so. For, after all, a patent is not a giving to science, but simply a commercial affair, and such and such only it must be dealt with. You will have noticed "Ex Cathedra" comparisons with fifty years ago, and the remarks thereon.

There is one question to consider—which rarely seems to be considered—in addition to novelty, utility, and cost of manufacture, which, for want of a better word, may be called opportunity. To obtain, what good to the patentee is his patent if he is unable to place the article on the market? Look at the patent columns. Shutter improvements—Pickard, Camera improvements—Watson. These men are shutter makers, camera makers, already. A very small improvement to them is worth a patent, because it becomes a part of their existing business. That is the crux of these, often, minor improvements.

How many thousands of plate-changing hand cameras were invented in the dozen years ago. Let us look at the question practically. Required a mechanism to change plates; could not any mechanical man of thought produce something. A manufacturer or one of his staff works out some design, and it is made. He will not trouble himself to take up somebody else's patent (without considering the question of validity) unless it is in truth something entirely new and marketable. I remember constructing half-a-dozen different ones. We used to call it "hand-camera fever" in those days, but the disease never got so far as the Patent Office.

Even with a novelty there is no certainty of being rewarded with so much of a return as the value of fees expended. Having a patent, what are you going to do with it? Start a company? That requires money or influence. Manufacture it yourself? That requires money and capacity. Sell it to a manufacturer, or get him to make it on royalty? Not so easy unless your patent is a remarkably inclusive one. Inclusive, not because our manufacturers are less honest than any other persons, but for the simple reason that A will not pay to be allowed to produce an article that B will almost copy and produce without paying anything. One cannot look through the "Almanac" advertisements without being reminded of this.

And there is another side to this infringement question. As the Editor is often telling his correspondents, a copyright does not prevent another copying, it only gives right of action. You have a patent, and it is infringed by a big firm (unknowingly or knowingly, or doubting your validity). What are you to do? Bring an action, when they obtain some of the most eminent counsel and expert opinion? Can you afford to do it?

Again, in the Patent Office there are records of all patents; have you searched through all of them? It is a very long and tedious affair. Few matters have not been the subject of patents, often unwork-

able it may be, but needing search and care. No searches are made by the Patent Office authorities; if specification is in order they take your money and give you your patent, whether they have given the same thing to Smith, Brown, Jones, or Robinson, or all of them, the day before. There are books of index and reference, however, in their library to help you. But though it is a free library, it seems to be somewhat infrequented by the inventor, from the constant repetition that may be seen there. This search can certainly be executed by patent agents, and the application and specification drawn up by them. It is their business, and doubtless they know better how to do it than you do yourself. More expense!

The preliminary to a patent, "provisional protection," costs a guinea. It seems cheap. But a guinea is a guinea, and why throw it away? Probably that is all an inventor would do, if, inexperienced, he drew up his own preliminary specification. It must be borne in mind that although a fuller specification is allowed no new thing can be added; no real alteration can be made. I mean that the professional skill of the necessary and expensive agent is as necessary for this, too.

There seems to be considerable misunderstanding in the lay mind as to this provisional protection. A man gets provisional protection and thinks he is protected. He is not. There is one more thing he must do. He must publish his process or design. He must not keep it secret as so many do. As to the publication, there is no need to cry it in the streets or from the housetops. A notice with particulars in the "Slocum-in-the-Mud Weekly." A pamphlet published (not necessarily distributed) and sent in the usual course to the British Museum, is publication sufficient, for the Museum library is open to the world. Novelists favour the National Gallery for certain purposes, so might the inventor the British Museum Library. Sufficient publication, too, would be an explanation or exhibition at a meeting of the member's society, without prohibition or secrecy.

The reason for this is a simple one. No one may patent a thing that is not new (or rather such patent would be useless). The particulars in the provisional specification are not given to the world, but kept private at the Patent Office for the period allowed—nine months. Anyone, therefore, in the meantime taking out a full patent (complete specification) for the same thing would have precedence, unless the world (as the British Museum) had been told the secret by the first man. And as there is often no need for secrecy, why trouble.

In conclusion, if you must patent, go to the Patent Office Library, and read what others have done in the same line. Then go to a first-rate agent. And in all things be prepared to pay. To put it shortly, for a man not "in the trade," only a big patent, one worth the expenditure of a large sum, is generally worth being patented at all. I am, yours, etc.,
A BARRISTER-AT-LAW.

April 22, 1904.

THE NORTHERN EXHIBITION.

To the Editors.

Gentlemen, One reads from time to time a good deal of criticism in respect to the affairs of the Royal Photographic Society, but as a mere outsider I cannot help contrasting the methods of the "Royal" and my treatment as an exhibitor, with the methods of the Committee of the Northern Exhibition. But you naturally say, "Why make a contrast?" Well, I will explain.

For a few years I have exhibited at the Royal. I send up my pictures together with the hanging fees, and in due course I am informed that such and such pictures are rejected, together with a receipt for the amount of my remittance, then comes a copy of the catalogue together with an invitation for myself and friend to the conversazione on the opening night, and, if I have any work accepted, a season ticket for the exhibition. Now, sir, this I consider Royal treatment. Mark the contrast. I send my pictures to Liverpool, together with the hanging fees, but I receive nothing in the way of acknowledgment and no receipt for my remittance. Then I see a report in the photographic Press of the opening night, brilliant success, etc., but as one of the contributors, no invitation has been extended to me, nor do I even receive a ticket that I may see the show. About a week after the opening I receive a copy of the catalogue, and this is my only official communication. Finally my pictures are returned, with not even a printed slip enclosed.

On Easter Monday I thought I would go over to Liverpool and spend an hour or two at the exhibition, and thinking I might do a little work on the river, I took my camera with me. In the afternoon I

wended my way to the Walker Art Gallery, and entering I turned to a youth in livery and asked him to kindly direct me to the exhibition. He in a very brusque manner replied, "At the top of the steps," and then added, "You can't take those inside," pointing to my camera and plate bag, so I said, "Why?" "Because," he replied, "you'll have to leave them here." I felt considerably annoyed at the rude officiousness of the youth, and my wife, who was with me, said "Come along, we won't go in." I thought it best, however, to make a virtue of necessity, and so handed them over at a charge of 2d. I then continued my way until I came to the ticket office of the exhibition. Before purchasing a ticket for my wife and myself I inquired from the official, "if exhibitors were charged for admittance," when he said, "I don't know—everybody that goes through here pays." I said, "Well, it isn't usual I think!" and he replied, "I know nothing about it—if it isn't right the secretary is inside, you had better speak to him and ask him to refund the money." I must confess that I felt very much put out, and to quote the words of the song, "It wasn't what he said, but the nasty way he said it," and I know in consequence that my enjoyment of the exhibition was brought to an untimely end. However, I paid my money and went inside, but I found no pleasure, and was glad to get out after spending less than half an hour. So, sir, I spent six hours in a railway train and a day in Liverpool, and had my outing completely spoiled. By what?—The lack of a little common courtesy. When I got back to the cloak-room I found a fresh attendant, who, instead of giving me what I had deposited, handed me an overcoat, and kept me waiting a considerable time when I explained to him that I wanted a camera and not a coat. I then left the Walker Art Gallery and got the first train home, after shaking the dust of Liverpool off my feet—that is briefly my experience of the great "Northern Exhibition." I do not know whether or not I am voicing the complaint of any other exhibitor, but I can assure you that I shall think carefully before I contribute another sovereign to the success of future Northern Exhibitions.—I enclose my card, and subscribe myself, yours faithfully, "A DISGUSTED EXHIBITOR."

April 25, 1904.

SOME NOTES ON THREE-COLOUR WORK.

To the Editors.

Gentlemen,—Mr. Baker is entirely wrong in assuming that I considered his notes as reflecting on my translation, but I did think it very nearly impertinent for anyone with only two years' experience in colour sensitising to question the statements of Dr. Eder, who has had thirty years' experience.

Your correspondent's remarks as to the article being out-of-date, etc., are not impertinent, they are only rude, and show how little he knows of the subject, and although two years old there are points in it which have never before been touched on by anyone.

I was not aware that Mr. Baker was endeavouring to commercially exploit these dyes, or I should not have taken the slightest notice of his article; still, as the translation in my previous letter proves that these purple black dyes can be used successfully, the only conclusion I can come to is that, notwithstanding his long daily experience and laboratory equipped regardless of expense, he is not yet an expert manipulator, and were it not that he has such an utter contempt for authorities, I could refer him to one that would probably clear all his troubles away.—Yours faithfully, E. J. WALL.

Foots Cray, April 25, 1904.

PSYCHIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—Please find enclosed a few untuned spirit pictures. I have been very interested by the articles appearing in the Journal.

It seems to me that your correspondent of Friday week last is making fun of the thing altogether, and also seems to think the method of producing them should be made public.

I think he had better exert his brains, as I had to do before succeeding in it, for he will find it is not such an easy matter, but it pays for it in the end, as I am now receiving from £3 3s. to £55s. per dozen for spirit pictures.

By this I mean that, supposing a man lost his wife, or vice versa. If I had a description of the departed one I could photo the living one, and the departed one should be by his or her side.

Also, a family who have lost several members and would like a family group taken, the departed ones included. By coming to my

place and giving me a description of the lost ones, or showing me photo or drawing of them, I will take the family group, and include the departed one, who shall be in their right position in the finished picture.

Trusting you will excuse my troubling you with this matter, but there seems to be a lot of controversy about it, I thought, perhaps, might settle the matter that others besides Mr. Blackwell can do the —and without the aid of spirits.—I am, gentlemen, yours truly,

J. LAURANCE.

The Sackville Studio, 7, Sea Road, Bexhill-on-Sea,
April 26, 1904.

CINEMATOGRAPH PATENTS.

To the Editors.

Gentlemen,—I note in the last issue of your Journal an anonymous letter signed "A Cinematographer." As a matter of fact this letter already answered by my letter which you have published. However, had the writer of this letter considered it of sufficient importance to sign his own name, I would have taken the trouble to answer it—as I would be pleased to do any other letters you may see fit to publish signed by their authors. I, however, have other things to do besides answering anonymous letters, whether they be addressed to me personally or printed in your Journal, and do not propose to take the trouble of answering anyone who has not sufficient belief in the importance of his own statements to sign his name. I have received some forty odd letters from various old assistants of mine referring to the early phases of this invention, which I have not had time personally answer, and would take it as a personal courtesy to me if you would kindly express to them, through your columns, my deep appreciation of the kindly interest toward me which these letters show.—Yours sincerely, W. FRIESE-GREENE.

Millbrook, Dovercourt, April 26, 1904.

PROPOSED TARIFF REFORM.

To the Editors.

Gentlemen,—So far the question of the proposed retaliative taxes on imported goods has not been adequately discussed in the photographic papers, at any rate in their relation to photographers. One reference to the subject appeared in a contemporary, supposed to be written by a professional, but the ignorance displayed was so great as to make it appear quite impossible that any professional could have known a little of the subject. It was stated that the proposed changes would make no difference to photographers, as scarcely any of their goods were imported, except a few mounts from France. Now surely every professional knows better than this. An enormous number of mounts come from Germany, and within the last few years a large quantity, especially of the finer quality, are American. These presumably would be taxed, as they can scarcely be regarded as raw material. Photographic chemicals, too, especially developing agents, come in vast quantities from Germany. Probably almost the whole of the raw material for sensitised paper comes from abroad, and no doubt, the paper-makers of this country would object to such goods coming untaxed as raw material. The glass of which dry plates are made comes from abroad in considerable quantity; this again could scarcely be untaxed as raw material. It is tolerably certain, then, that when such new arrangements are made, and made they will be sooner or later, professional photographers will have to pay more for nearly every article used in their business, unless the producer pays the tax as we are assured by some, they must do.

At first sight this is a serious outlook for those who earn their bread by photographic work, for an increase in the cost of materials means a proportionate reduction in the profits obtained, unless higher prices can be secured for the finished photograph, or a larger amount of business can be done.

The question is a very serious one, and it is as difficult as it ever was to foretell the future. But the present state of business is equally serious. We find on every hand that trades and manufactures are suffering from unfair competition. Goods are being imported to be sold at a cheaper rate than they can be manufactured here. Some will say, "So much the better for the photographer, for the cheaper he can buy his material the more profit he can make." This is a very superficial view to take, for the prosperity of the photographer depends on the prosperity of the community, and if one section of the community suffers all must lose in the end. We are naturally dependent upon our

her. In the Midland district several trades have been almost wiped out by foreign competition; for example, button-making, nail rivet-making, are almost gone. Yet the first-named was once a very important industry, and German wire nails, it is said, can be bought for less than the wire costs here. The jewellery trade in Birmingham is suffering severely from foreign imports at low prices. It may surprise some to learn that the jewellery trade of Birmingham is large and important, and it does not produce only "lacquered ware," or "Brummagem ware," but that nearly the whole of the English jewellery, including the best London, is made in Birmingham. The boot trade is suffering in the same way. It is possible to buy English boots here at 16s. 6d. a pair, which cannot be bought in America for less than 25s. The list might be continued to a much greater length, and when all these trades are suffering photography must suffer too.

It is said that these things will right themselves, and that although Birmingham has lost its staple trade of ribbon weaving, it soon established a prosperous watch trade, and when that went from the same cause cycles and motor cars filled up the gap. But the men who made ribbons did not become watchmakers, and the watchmakers do not build motor cars and cycles. They have had to go to the wall, and the cycle trade is threatened with large importations of foreign bicycles, and a wall of hostile tariffs is destroying the markets for English goods all over the world.

The English dry-plate trade is being threatened in the same way, the hostile tariffs are so rigorously enforced that some time ago a well-known American lady photographer was asked, on her return from America on a European tour. Under these conditions how is it possible for English manufacturers to remain prosperous? They are condemned for clinging to old methods, for not making scrap of their old machinery and putting down the newest in its place. But what would be the use when they see that do what they may a foreign article can undersell them? What encouragement is there for a manufacturer to spend thousands of pounds on new machinery when German goods are sold for less than he pays for the raw material? And the American maker can do it at a profit because he can get high prices for his same goods in his own country.

This is an extremely difficult question, and whether the proposed remedies will be effectual it is impossible to say. But one thing is certain that when the change is made photographers will at first suffer. Whether they will suffer more if the present state of things continues can be told, and whether the proposed taxes will eventually benefit them is equally uncertain.—Yours truly,
HAROLD BAKER.
1, Cannon Street, Birmingham.

BARMANS. Special.—Photo. Canvasser's Dishonesty.—On four charges of having obtained money by false pretences, Henry Spare, who has lived at the Corporation lodging-house in Ancoats, appeared before Mr. Brierley at the Manchester City Police-court to-day. Wm. Cobbett prosecuted on behalf of Messrs. Eddison, Limited, photographers, of Manchester and elsewhere, by whom the defendant recently engaged as a canvasser. The allegation was that Spare went to public-houses and solicited orders from barmen and barmaids, representing that his firm were offering to such persons special rates of 2s. 6d. (instead of 12s. 6d.) for six photographs, and in some cases saying that they were to exhibit the photograph in the public-house. The coupon books with which the firm's canvassers are supplied, said Mr. Cobbett, stated the only authorised terms, in most instances the defendant had made an alteration in the coupon, or endorsed it to the same effect. In this way he obtained copies of half-crown payments, for which he had not accounted. An employee of the firm said they had no such "barmen's and barmaids' special," as the defendant had represented. Detective-inspector Ridings brought two other charges against the defendant of obtaining a postal order for half-a-crown by false pretences. These had obtained as "booking fees" from persons answering advertisements—in one case from a barman, in the other from a coachman. The defendant admitted his guilt, and said he came to Manchester in search of employment, but could not get it, and became destitute. On obtaining the situation as a canvasser he gave way to temptation. A sentence of four months' hard labour was passed.

Answers to Correspondents.

* * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

* * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

H. G. PIKE, 34, High Street, Reigate. Photograph of Castle Grounds, Reigate.

H. W. HAYNES, 13, Cumberland Park, Acton, London. Photograph of Past and Present Members, Acton Urban District Council.

J. WICKS, 41, North Gate, Slaford. Photograph of the Manor House, Slaford.

A. B. BURKIN, 21, Reforme, Portland. Two Photographs of a Military Funeral at Portland.

E. RIDDLE.—We do not think you are asking too much for the prints. We have followed your instructions and inserted advertisement to effect your desire.

J. SHAW.—On the facts as stated in your letter we think you could make a claim against the firm who has pirated your print. Your best plan is to place the matter in the hands of your solicitor.

CEMENTING GELATINE.—"PHOTOPHIL" asks: "Would you, please, say what is the best method and adhesive for firmly and flatly uniting two films of gelatine without any expansion of either?" In reply: If the films are gelatine, pure and simple, moisten them with a dilute acetic acid, press in contact, and keep flat till dry; or plain water may be used if slightly tepid.

A. L. CRANCH.—You do not say whether you desire a situation as a studio operator or press photographer. In the former case the prints give no clue whatever of your abilities beyond being fairly good snapshot photographs. In the latter case so much would depend on your own initiative for securing the right thing at the right time that lack of knowledge of the facts precludes our offering advice. Let us hear from you again.

BOOK WANTED.—"KRAM" writes: "(1) Will be very pleased if you can give me the name of the best book on retouching? (2) I am enclosing some prints taken from negatives which I have retouched. I should like your opinion of them. Do you think I will ever be a good retoucher?" In reply: (1) "The Art of Retouching Negatives and Finishing and Colouring Photographs," by Robert Johnson, is a good book. (2) With practice we see no reason why you should not become a good retoucher.

THREE PER CENT. COLLODION.—J. ADAMSON says: "A German formula gives 900 c.c. of a 3 per cent. collodion in wet plate work. What would be the proportions of gun cotton and alcohol and ether to make a 3 per cent. collodion? How many grams of pyroxiline to the 100 c.c. of liquid, or the simplest way it can be put to make up?" In reply: What is meant is three grammes of pyroxiline to ninety-seven c.c. of a mixture of equal parts of ether and alcohol.

DEVELOPER.—"FOCAL PLANE" asks: "Will you, please, tell me the best formula and best method of developing plates exposed by a focal plane shutter at 1-1,000th of a second? I use for ordinary work pyro ammonia." In reply: Any developer. What has the form of the shutter to do with the developer, supposing the plate is fairly well exposed? If it is very much under-exposed, and probably that is what you anticipate. Metol or rodinal will, perhaps, bring out as much detail as any developer.

TROOPER asks:—"Will you please give me a formula for painting a background dead black (on canvas)?" In reply: Stretch canvas tightly (on wooden frame if possible), thoroughly wet it (with a watering pot), and cover the surface with equal parts of lamp-black and dextrine, sprinkled from a fine sieve. Then rub the colour in with a stiff brush. Black "Kalko" background paint,

sold by the Vanguard Company, is also good, and convenient to use.

TEST FOR HYPO.—"LAD" asks: "(1) How to detect traces of hypo in paper? (2) When detected in paper on which photos are going to be mounted how to remove same without destroying paper?"

In reply: (1) Soak some strips of the paper in distilled water, in a test tube. Then make a solution of permanganate of potash—say a dram in five ounces of water, and acidify with a couple of drops of sulphuric acid. Next dilute some of this with water until it has but a very faint tint. If, on adding a few drops of the water the paper was soaked in, the colour is discharged and the paper contains hypo. (2) There is no method of removing it without disturbing the surface of the paper.

STAINED PRINTS.—A. WALLHAUSER writes: "I should be obliged if you would inform me as to the cause of yellow stains on enclosed print. They appear in the toning bath made up of gold and sulphocyanide. I washed the print with others for ten minutes in running water, then I put them in an alum bath for ten minutes, and then washed them again for twenty minutes before toning, and about a dozen turned out in this way. As a rule I am very careful with my toning, and have never had anything like this before." In reply: The stains are evidently due to contact with hypo, probably from an unclean dish being used for the washing of the prints.

COPYRIGHT.—"SMOKER" says: "I am reading your articles on the law of copyright with enjoyment. May I trouble you to answer one question. Take, for example, the group I enclose. It was taken at my own risk, no money consideration. If a gentleman who is in the group, and who buys a copy likes himself sufficiently (1) Could he go to another photographer and have copies of himself taken from it? (2) Could he have copies of any other gentleman (who might be an old friend) produced? (3) Or would such acts as above be an infringement of copyright. (4) Or must the whole photo be copied to constitute an infringement?" In reply: (1) No, not if the copyright is yours. (2) No. (3) Yes. (4) No. Copyright covers all portions of the picture.

STUDIO QUERY.—"A. A. A." says: "I shall be glad of your advice on the following:—I have the chance of shop, etc., but space at back will not allow of studio wider than nine feet; would you advise so narrow a studio. Not having worked in one so very narrow, I feel doubtful if the class of work I do (the best) could be carried on in so narrow a space. The light is good, being north-east, and length ample for studio—from 30 to 35 feet. It is only the width I am doubtful about, so shall be glad of your advice on the same, or shall I wait and look out for a more roomy place?" In reply: Nine feet is certainly narrow for a studio for professional work; still good portraits may be obtained in one of that width. The difficulty in so narrow a studio is in taking groups, not single figures.

STUDIO.—WESTLEY says: "My studio here faces west, and I get a strong sun from about two o'clock. Could you give me any advice as to the best means of overcoming the difficulty—screens, curtains, blinds, etc., I am using in abundance. It is not glazed with ground glass. Would it be worth my while to have ground glass put in? Could you also give me a word as to what means you would advise for keeping the studio cooler?" In reply: You might stipple the glass in the roof over with starch or flour paste to which some whiting has been added. That will answer the same purpose as ground glass. Or you may fit the roof with light wooden screens covered with tracing linen. Good ventilation will tend to keep the studio cool. A fan, driven by an electric motor will keep a current of air through the place.

A. E. WITTY asks: "I wish to get permission to photograph parts of (Greenwich Park, and I find from information in your Almanac that I can do so on production of the 'Red Book.' Can you inform me what this is and where obtainable?" In reply: The "Red Book" is issued by the Royal Photographic Society to its members, and to members of affiliated photographic societies. The "Red Book" besides representing the official voucher of membership also confers certain desirable benefits and privileges on its owner, one of which you mention, and all of which are detailed in the "British Journal of Photography Almanac."

Your best way to become the happy possessor of a copy is to join the nearest affiliated Photographic Society, or become a member of the Royal Photographic Society. The Secretaries will send you all particulars if you write to 66, Russell Square, London, W.C.

DEVELOPER.—"S. E." says: "I shall be glad if you will inform me if you think that it is as cheap to use 'brilliant' developer for professional use as to use pyro-ammonia. I buy the 'brilliant' in quart bottles at 3s. 6d. each, and the soda for use with bottle costs, I suppose, about 3d. or 4d. I use it in the same way as a toning bath (i.e., pour the solution back into a bottle each time and just strengthen it up for use). I have to develop on an average about twenty negatives a day. As it in time becomes thick and muddy, would it do for me to filter it, should I by so doing weaken its action?" In reply: "We have had no experience with the developer named—nor do we know its composition. We should think that our correspondent, who develops twenty negatives a day with it, would be able to judge whether it is more economical to use that or pyro. Of course all developers lose energy the more they are used. Filtering the solution will not weaken it."

ADULTERATION OF Potassium Cyanide.—L. F. Kebler complains that potassium cyanide, labelled "98 to 100 per cent. pure," is frequently imported into the United States in a state of gross impurity. Analysis of four samples showed the percentages of KCN to be 33.65, 13.31.75, and 65.90 respectively, the remainder consisting of sodium cyanide in very large quantity, with potassium carbonate, and in some instances sodium chloride as well. The author remarks that present methods of detecting and determining chlorides in the soluble cyanides are not satisfactory, and more expeditious and accurate tests desirable.—U.S. Department of Agriculture Bulletin.

DETERMINATION OF Formaldehyde.—C. Kleber suggests the following method for the quantitative determination of formaldehyde:—A commercial concentrated sodium bisulphite solution, which generally contains a considerable quantity of free sulphurous acid, a solution of pure caustic soda, preferably made from the article purified with alcohol, is added, until the odour of sulphurous acid has completely disappeared. No special care is required in this operation, as a slight excess of caustic soda over the quantity necessary for deodorising is immaterial. Then this solution is diluted with water, until 30 C.c. it exactly neutralises 50 C.c. of normal caustic soda, using phenolphthalein as an indicator. Towards this solution formaldehyde behaves like an alkali, and can be titrated accordingly.

AMONG the recent additions to the art collection in the Victoria and Albert Museum are three cases containing original drawings, a work of modern English book illustrators. Phil May is represented by a characteristic study on brown paper, and by several pen-and-ink drawings for process reproduction in "Punch" and elsewhere. Next to them are two pen-and-ink drawings by Charles Keene, reproduced by wood engraving in "Punch." G. Du Maurier's original pen studies and finished pen-drawings for "Punch" are exhibited along with proofs of the wood engravings. The work of Frederick Barnard is illustrated by three characteristic drawings in pen-and-ink. There are also four mounts containing nine original water-colour drawings by Kate Greenaway, made for her well-known picture books.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography
The Oldest Photographic Journal in the World.
ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.
TERMS OF SUBSCRIPTION. Post Free

JUBILEE OF "THE BRITISH JOURNAL OF PHOTOGRAPHY."

STORIES of the British newspaper Press invariably make attractive reading. The foundation, growth, and expansion of the vastly circulated publications which exercise such commanding influence on the national life, supply the historian, as a rule, not only with material for important contributions to the records of industrial progress, but also with the opportunity of relieving his book by some piquant touches of a personal nature which contrast the high lights of human interest with the sombre shadows of his subject. As in the more prosaic walks of life the element of romance occasionally asserts itself, in the world of Press administration, and a lambent glamour of mystery attaches to every member of a newspaper staff from the able youth irreverently known as the "printer's devil" up through the entire organisation up to the Grand Editor-like occupant of the Chief Editorial chair himself. The fascinating story of the lay Press may, then, always be trusted to delight the general reader, who, however, in the cases out of ten, is probably unaware that the popular daily and weekly newspapers do not meet all the requirements of the serious student of commercial, scientific, or industrial progress. Hence it is that we have but so much that comparatively unknown but still very powerful in the Press termed "class" journalism. Your ordinary daily or weekly newspaper which deals with the general trivialities of the moment is read, flung aside, and, in most cases, forgotten in a few hours. Not so your technical journal which voices and represents one's principal interests in life. In this respect no ponderable gap in the community is neglected or unrepresented;

every trade, profession, or occupation being catered for by competent writers and authorities. An exhaustive history of the technical Press since its virtual foundation in the earlier part of last century might be made in great measure to take the place of an industrial history of England so intimately is the work of the Press associated with what goes on daily in the nation's workshops and manufactories.

Tempting as the theme is, it would be foreign to our present purpose to enlarge upon it, even were it possible to devote the necessary space to the treatment of a subject to one section only of which, on this occasion, it is our obvious intention to address ourselves. Readers of these pages for the past few months will not need reminding that from time to time we have reprinted, under the title of "Fifty Years Ago," extracts from the "Liverpool Journal of Photography" of 1854, of which the present journal is the direct dynastic descendant. Curious it is to, as it were, sweep the mental gaze back over the broad gulf of half a century, and, making the familiar comparison of "now" with "then," note the fact that in those subjects of general interest and discussion which occupied the minds of photographers fifty years ago, time to-day has wrought little change. Processes have altered, improved, or advanced; the field of their application widens from year to year, but nevertheless the scope and possibilities of the "black art" were quite as fully recognised in 1854 as the then existing state of knowledge permitted.

Recent Royal usage has associated the completion of a Jubilee with the occasion of rejoicing. Authorities are not agreed as to what a Jubilee really is, or what particular number of years it signifies—two, seven, twenty-five, or fifty. Since 1887, however, the mighty arbiter, Custom, in obedience to which we all make deference, has decreed that a public person, or institution, boasting, as such, a continuous career of fifty years before the world, may legitimately make the fact the subject of self-congratulation and invite the sympathetic countenance of friends and contemporaries in the celebration. So it comes about, therefore, that in this year of grace—1904—THE BRITISH JOURNAL OF PHOTOGRAPHY takes pride and pleasure in the reflection that it passes into the second half century of its existence. The first number of the oldest photographic journal now extant was published in 1854, and thus our fiftieth year was completed in December, 1903. Consequently January last should have seen this present announcement, which was deferred till a season of the year more convenient and congenial to celebrations of the kind.

To prove that the history of THE BRITISH JOURNAL OF PHOTOGRAPHY during its fifty years' life if written out in full detail would practically constitute a voluminous history of the "art-science" which the JOURNAL WAS deliberately founded to foster would, we

submit, not be a very difficult thing. But such a history in the form suggested would necessarily be somewhat partial and coloured by the not unnatural egotism of the pardonably self-aggrandising journalist. The history of photography has never yet been written, and never will be, until the work is taken in hand by some as yet undiscovered master of historical research thoroughly well qualified to collect, sift, and weigh evidence, and thus do for photography in general what has been done for one particular branch of it—the lens—by the accomplished authority, Dr. Moritz von Rohr, of Jena. When that history comes to be written it cannot possibly escape notice that at various epochs this JOURNAL has had a direct and most important influence upon some of the most momentous advances in photography, and we trust that we may be pardoned for recalling those circumstances on this occasion and subsequently.

We shall, indeed, recall them more in detail on June 10th next, when, in order to commemorate the completion of its fiftieth volume, we propose in a special supplement to the ordinary issue of THE BRITISH JOURNAL OF PHOTOGRAPHY of that date, giving a history of the paper and those who have been associated with it since its foundation. The story, we have no doubt, will make interesting reading in respect of both its journalistic and photographic aspects. Avoiding for the moment any further reference to the former feature, it will be our object to show that the JOURNAL and those who have had the honour of being attached to it during its career have all along rendered great services to the cause of photographic progress. Addressing itself primarily to the advancement of knowledge in photographic technique, the JOURNAL has steadily encouraged every step forward which has had for its object the perfection of photography as an instrument of scientific precision. At the same time it has not neglected to promote and advocate the material well-being of those whose interests are bound up in the commercial phases of photography. To enumerate in detail, however, the many aspirations which the JOURNAL has always assiduously encouraged would amount to an anticipation of our issue of June 10th, wherein all this, and much more, will be written about. In truth, it is a pleasant, enthralling, and withal very human little history, that of the BRITISH JOURNAL OF PHOTOGRAPHY, which the present Editor-in-chief regards as one of his most cherished privileges to have the opportunity of writing. And, perhaps, it may be permitted to him to add that these feelings of gratification are somewhat sobered by the regret that so many of those who rendered loyal service to the JOURNAL in past years are not here to-day to share in the permissible exultation of those nowadays associated with the paper, in the fact that after half a century's existence the "old B. J.," to quote the colloquialism of the moment, is "going stronger and better than ever," and has marked out for itself a future of aggressive vitality and unrestrained progressiveness which will assure to the second half-century of its existence a degree of success, prosperity, and usefulness far greater than that of its first.

A DARING robbery was attempted on Saturday morning shortly after six o'clock at the premises of Messrs. Sinclair and Co., opticians, Haymarket. Two men broke the plate-glass window of the shop, and extracted a tray containing twenty-four gold pendant compasses, valued at about £40. A policeman on special duty outside a shop just opposite, hearing the sound of the breaking glass, dashed across the road and captured one of the men after a short chase. The other man ran off in the opposite direction. Eventually the man was captured, but it was then discovered that he had got rid of part of the spoils, and it is believed that he was assisted by accomplices. This is the second time that Messrs. Sinclair's window has been broken, the last attempt having been made on Easter Tuesday.

EX CATHEDRA.

New Lens Glass.

The use of the various kinds of glass made at Jena has revolutionised the construction of lenses, especially photographic, combination being now made possessing properties which not long ago were pronounced impossible by many experts. A further addition to optical powers seems possible, indeed, probably by the introduction of another medium for the manufacture of optical instruments—vitreous silica. Recently a paper by Messrs. J. W. Gifford and W. A. Shenstone, the "Optical Qualities of Vitreous Silica" was read before the Royal Society, and the feeling has been expressed that this substance is likely at no distant period to play an important part in optical work, and, if the cost of the material and its working should not be prohibitive, photography in certain directions should be distinctly aided. The authors of the paper have made a number of measurements of the optical constants of the new material, which possesses great uniformity of composition, combined with transparency to ultra-violet radiations, while, unlike quartz, it is not doubly refracting. To test the homogeneity and, consequently, perfection of refracting power of the new medium, four slabs of it were prepared, cemented together, and from the mass a prism cut and polished. A variation of density on any one of the slabs would have so affected the refraction as to render the prism useless as an instrument of precision; but so far was this from being the case that when tested against a similar prism of boro-silicate glass from Jena, all the slabs being from the same melting, the silica prism was found to be distinctly superior. A thin doublet had been made and described; it had the vitreous silica for one component and fluorite for the other; the focal length of the combination is almost independent of the wave-length, in other words the achromatism was almost perfect.

* * *

Electro-plating Aluminium.

The undoubted usefulness of aluminium in the use of photographic lens mountings, camera fittings, and so forth is not fully recognised by the general use of the metal for such purposes. The increased cost, perhaps, has something to do with the weathering, but there must be other causes. Probably its appearance influences camera users, for it must be admitted that the metal, when worked up, has not an attractive appearance, even when lacquered; when unlacquered it very rapidly attains a very unlovely leaden appearance. An improvement upon these qualities appears to be possible according to an article in "Electro-chemical Industry" by Messrs. C. F. Burgess and Carl Hambuechen, who have invented a method of electro-plating aluminium with any desired metal. The difficulty in such plating hitherto experienced has been considered to be the instant formation upon the surface after cleaning of a film of oxide, which prevents a cohesive coating being formed. A theoretically perfect plating bath is the one which would dissolve the oxide and allow the deposition to take place at the same time. This is brought about under the new invention by the addition of a soluble fluoride or a small quantity of free hydrofluoric acid. Then it is necessary to give a first plating of a base metal which will adhere tenaciously, and zinc is found to answer. After this, other metals, such as copper, etc., may be deposited on the zinc, using the ordinary precautions for plating in that metal. Singularly, gold cannot be satisfactorily deposited on the zinc direct, as, after the lapse of a short time, it seems to sink into the zinc, and almost disappear. If, however, a preliminary coating of copper be given, the gold coating remains perfectly adherent. It is perhaps too much to expect fold-plated aluminium mountings for lenses, but the

ould be the acme of luxury, and, as a good lens can be made in small bulk, the expense should not be prohibitive, and the idea cannot be said to be wildly utopian.

New ch in ar Physics.

Under this title, Dr. Wm. J. S. Lockyer, in "Nature," gives an abstract of a paper in the "Publications" of the Yerkes Observatory which records a triumph of photographic work produced under the guidance of the skilled hand and brain of Professor Hale working on lines indicated by Sir Norman Lockyer, M. Jaanssen. The application of the spectro-scope to the telescope in the manner devised by these two astronomers rendered possible the making of observations—without the intervention of an eclipse—upon the sun's disc and prominences, greatly adding to our knowledge of the sun's circulation. But these were all accomplished by the eye; the spectro-heliograph enabled photography to step in, and the latest form of this instrument is described in the paper referred to. The feature of the instrument is that it is capable of giving pictures of the sun in light of one wave-length—i.e., in monochromatic light. The instrument itself differs little in principle from the ordinary spectro-scope whose eye-piece is removed and replaced by a second slit. If the solar image be thrown through a lens upon the first slit, then after the solar image has passed through the lenses and prisms of the instrument it will fall on the second slit, which will only allow a narrow portion of the spectrum corresponding in wavelength to this slit to pass through it. The second slit can be adjusted so as to receive any particular line of the spectrum and completely isolate it. If now the solar image falling on the first slit be kept stationary, and the spectro-scope be moved in a flame at right angles to the axis of the incident solar beam, and in a direction at right angles to the length of the first slit, then the light which will pass through the second will be a succession of images in monochromatic light, corresponding to the strips of the solar image which entered the first slit. As an example, if the second slit be adjusted to receive, say, the "K" line of calcium, and placing a photographic sensitive plate almost in contact with the surface of the second slit, while the first slip is passing over the solar image, the second is moving over the stationary dry-plate, and thus the monochromatic "K" light to impress its successive images on the plate. The result is a picture of the sun in "K" light, and, by isolating different lines in a similar manner, various monochromatic images of the sun in different "lights" may be obtained. Professor Hale decided to employ the spectro-heliograph with the great refractor, and had, in consequence, to make special adaptations to this end, as the movement of the instrument as above would have caused a vibration that would have ruined definition. He therefore decided to keep the spectro-heliograph still, and to cause the solar image to travel across the first slit by means of a rotation motor. This necessitated a further device, the dry-plate being to traverse at the same rate as the image. Professor Hale connected the plate-holder directly with the rotation motor, and thus the two were moving simultaneously. A new field of research which apparently has not been opened up, Dr. Lockyer writes, to take advantage of it three stations would be required for the study of the element, and to take full advantage of the new method a number of stations would have to be established in the fashion needed for the star atlas. His justification for such a recommendation is that a study of the changes in the sun is vital for the clear understanding of the changes in our terrestrial variations which are so closely connected with our everyday life, and that the necessity of such a programme is obvious.

THE FUTURE OF PHOTOGRAPHY FOR EMPLOYEES.

THOSE of our readers who make it a rule to look through the "Answers to Correspondents" column week by week must frequently have been struck with some of the inquiries we have to reply to. A very frequent one of late has been as to our opinion of the merits of somebody's work as an operator or as a retoucher, and what salary he should command as an employé in either capacity. Sometimes the examples of work sent, possibly picked specimens, have been tolerably good, at others just the reverse, and they serve to illustrate that the sender has no idea whatever of what is required from a good craftsman, either as an operator or a retoucher, or the two combined. Many of the former's specimens, though they may be good, clean photographs, show that their producer has but little knowledge of lighting the sitter, and far less of posing him or her; indeed, some of the poses have often been of a most inartistic character. The same may be said with regard to some of the examples of retouching we have received, as they show that the senders have no idea of drawing or the anatomy of the face. The notion seems to be, in the majority of cases, to work out every line of the face and make it appear as smooth and even as the wax-figures one sees in hairdressers' shop-windows. In some cases the likeness has been almost entirely destroyed through the total obliteration of the most striking features of the model, the face being rendered flat and inanimate to a degree.

It is evident from a very large number of the specimens we have received that the senders have quite mistaken their avocations, as they clearly imagine their work to be good, or, at least, sufficiently so to obtain them employment—and so it may, of a kind. It is this sort of thing that has brought about the over-stocking of the labour market with mediocre workers, who are frequently glad to obtain employment at a wage even below that of an ordinary unskilled day labourer. At the present time, when plates are bought ready for exposure in the camera, there is really very little for an operator to learn before he can produce a good and clean negative.

The chief skill now required is in the lighting and posing of the sitters, and being able to deal with them with tact and in a gentlemanly manner, so as to secure portraits of a refined and artistic character. These qualifications do not seem to be recognised by a large proportion of the candidates for appointments as operators. Many seem to surmise that if they can produce a clean negative, that is all that is necessary to secure them employment. It is perfectly true that the highest class operators—even in the best studios—do not get the same high salaries that used to be paid in the wet collodion days. But four or five guineas, and upward, a week are still paid; but, then, it is only to gentlemen of good education and with exceptional artistic ability. It is obvious that these qualifications are quite overlooked by some that think they are really good operators. An operator who may suit quite well for a studio of the "three for half-a-crown" type would be quite out of place in a high-class one where the sitters are mostly of the aristocracy.

In the above we have only been considering the male portion of photographic labour. But at the present time much of the work that used to be done by males is now done by females, and that does not improve the position of the former. A very large proportion—indeed, by far the larger proportion—of the printing and toning, as well as retouching, is now done by females, and it may be at once admitted that this work can as well be done by them as by males. But with them the outlook for the future is by no means bright. It has, for some years past, been a custom with very many to take girls as apprentices, with or with-

out premiums, for three years to learn printing, mounting, spotting, reception-room duties, etc., paying them quite a nominal wage, or none at all. After three or four months the apprentice, if fairly intelligent, becomes, with ready sensitised papers, able to do the work as well as those with long experience, and also to retouch negatives fairly well, if they have good tuition. She then becomes a valuable hand for the end of the term, and receives but quite a nominal sum for her services. Before she is out of her time—perhaps six months—another apprentice is taken on to learn the business, and she in due course takes the place of the former one, who then has to seek a situation elsewhere, and finds that it is by no means so easy a matter in the already over-stocked market as she or her friends were at first led to imagine, as witness the number of advertisements in "Situations Wanted" that appear weekly in our columns.

The advertisements "Situations Wanted" and "Situations Vacant" are always a good criterion of the existing state of the labour market. There is very little question that the present state of competition, with cutting prices, has been brought about by gelatine photography. It has tempted so many to become amateur photographers. As such they are able to purchase their plates and papers at about the same price as the professional, and they think, from the prices the latter—particularly those of the higher class—charge for their work, that photography must be a highly remunerative business, quite without taking into consideration anything beyond the mere cost for material. Hence they drift into professionals with very little ability as such, and, consequently, frequently adopt cutting prices. Some parents, thinking of the supposed profits of photography, article their sons for a term to some who almost make a trade of taking "articled pupils" with a very substantial premium; but what are the youth's prospects when he has served his term?

The object of this article is to point out to young people and their parents that at the present time photography, as an employment, is by no means so lucrative as many seem to imagine, and there seems to be but little prospect of its being better in the future. We therefore suggest that they should not enter the ranks of professional photography without giving due consideration to the matter.

THE COLOURED DAILY.—It is undoubtedly coming. But when? And by what means? Well, it must be process. It is curious that New York attempted a "Graphic" daily. It was to be by litho. It failed. London attempted a "Daily Graphic." This journal relies on process. It is a great success. The new daily in colours must be by tri-chromatic process method. Once again, we are ready.—"Half-Tone Times."

ASTRONOMICAL INSTITUTE OF EDINBURGH.—The fourth meeting of this society, since the present session opened was held on April 20, in the Philosophical Institution, Edinburgh. Mr. Wm. Firth, the President, occupied the chair. Mr. Heath, First Assistant Astronomer, Royal Observatory, Edinburgh, read two communications. The first was on the Solar Corona, which he illustrated by lantern slides prepared from negatives made by himself during the Scottish Eclipse Expedition to Spain in 1900, also by large photographs made by the Astronomer-Royal for Scotland by means of his 40ft. telescope, and kindly lent by him for the occasion, and in addition, by a selection of coronal slides made from photographs of those eclipses, and the observation of which photography had been employed with most success. The latter series included several obligingly lent by Mr. Wesley. Mr. Heath's second paper (also illustrated by many slides from his own negatives) embraced an interesting account of his personal experiences in Spain during the 1900 eclipse expedition—an account which the mature technical astronomer and the budding astronomical amateur alike seemed to enjoy thoroughly.

THE CRYSTALS OF AMIDOL HYDROQUINONE AND EIKONOGEN.

THE crystals of the developing agent amidol, when seen under the microscope, exhibit a very different formation to those of pyro, but are, under certain conditions, equally interesting and beautiful subjects for study. The crystals of amidol may be obtained from an aqueous solution as unlike pyrogallol and amidol will not dissolve in ether or alcohol.

Fig. 1.—Crystals of Amidol. Slow evaporation. $\times 50$.

A pyro deposit presents to the naked eye a regular and artistic grouping of crystals, but amidol requires the aid of a microscope to discover its beauties, as with the unaided vision it has the appearance of a dirty patch on the glass.

When preparing crystals of amidol for the microscope the solution must be quickly evaporated to produce the most varied

Fig. 2.—Amidol Crystals. Rapid evaporation. $\times 3$ obj.

effects. Slow evaporation produces the finest pyro crystals, but with amidol the deposit is too regular, and lacks variety. A photo-micrograph of the effect of slow evaporation is given in the first illustration.

the glass with the amidol solution should be warmed over a lamp. The resulting deposit, when examined under a low-power objective, will be found, for the most part, to be composed of uninteresting fragments, but here and there very

Fig. 3.—Amidol Crystals. Edge of deposit. 1 in. obj.

interesting crystalline effects will be noticed, especially at the edges of the deposit. The crystals of amidol give beautiful results with polarised light, superior even to pyro. The microscope should be rotated till a dark background is obtained

Fig. 4.—Hydroquinone Crystals from Ether Solution. 1 in. obj.

to bring out the best display of colour and form. Amidol crystals are usually of a very transparent nature, and on that account are not easily photographed. Fig. 1 is a reproduction of a photo-micrograph of amidol crystals, and gives the typical appearance of the deposit formed by slow evaporation. The crystals have formed in chains over the plate; the nature of the formation, however, is not particularly interesting.

Fig. 5.—Crystals of Hydroquinone Dissolved in Water. 1 in. obj.

Fig. II. shows the appearance of amidol crystals when the solution is rapidly evaporated. In this plate the crystals, instead of forming in chains, are broken up into floral designs in a varied and picturesque manner. Some of the crystals bear a curious resemblance to flowers and leaves of plants.

Fig. III. is from a photograph taken from the same preparation, but at the extreme edge of the deposit. These crystals have formed into a very fine group, and bear a striking

Fig. 6.—Crystals of Hydroquinone Dissolved in Water. 1 in. obj.

resemblance to palm leaves. There were several other similar deposits on the same plate, but these were the most perfectly formed. The adjoining crystals were included in the picture in order to give the general appearance of that portion of the preparation, though from an artistic point of view the palm tree should have been reproduced by itself. This group of crystals gave very remarkable effects with polarised light.

The crystals of another of the energetic type of developers, eikonogen, were examined by the writer, but gave very disappointing results. A solution of eikonogen after evaporation leaves only a few isolated crystals of no particular shape, and the few that are visible give little effect with the polariser. Hydroquinone produces many forms of crystals, and they are all of a different type to those of either amidol or pyrogallol acid. Interesting effects can be obtained with water, ether, spirits, or acetone as the solvent, and some of the typical formations are reproduced here.

When ether is the solvent long isolated crystals form, with a few broader specimens in some parts of the preparation.

Fig. 7.—Crystals of Hydroquinone Dissolved in Acetone. 1 in. obj.

Fig. IV. reproduces these crystals.

Fig. V. gives the result of evaporating a solution of hydroquinone in water. With hydroquinone rapid or slow evaporation makes little difference. Slight and very transparent crystals are formed, consisting of straight rods with projections on each side; the projections are generally much more prominent on one side than on the other.

Fig. VI. is another portion of the same preparation of crystals. In this photograph the lines run nearly parallel to each other at very regular intervals, with a thin line passing down the middle of each rod.

Fig. VII. is a photo-micrograph of crystals from an acetone solution. This is a very different group from those shown in either of the foregoing illustrations. The crystals are formed in broad masses instead of rods; but one or two groups somewhat resemble the radiating nature of pyro crystals. All forms of hydroquinone crystals polarise effectively, especially those just mentioned, Fig. VII.

J. I. Pigg, F.R.M.S.

ON THE DISCOLORATION OF BROMIDE PRINTS WITH AN INCIDENTAL CONSIDERATION OF THE ACID FIXING BATH.

[A paper read before the Royal Photographic Society.]

THERE are several sorts of stains or discolorations by which bromide workers are frequently troubled, and some from whom few bromide workers wholly escape; although some workers would assert that they never had any stains or discolorations in their bromide work. In order to obtain certain results in bromide prints one may use a very active developer which will be very prone to produce stains; and I think you will find that those who never get stains make it a rule never to use a developer that does not suit their particular requirements. To distinguish the various discolorations is the first step; to assert the supposed causes is the second step; and, in the third place, I propose to speak of a proper mode of working to avoid each kind of discoloration. These are:—

- (a) Greyness; slight grey fog over print; greyish whites.
- (b) Yellowness of the print.
- (c) Grey-brown discoloration.

All these are seen most upon the whites, of course, and are totally distinct from wrong colour or "tone" of the image.

The grey fog is the least often met with, and the most easily prevented. It arises from exposure to light while the paper is still in the sensitive state. An "unsafe" colour developing light may produce it before development, or the faintest reflection of white light from the walls and ceiling while changing and charging the frames, but so will an unsafe light during development. White light—at least with soft papers, during fixation, and, in fact, until the final salt is removed in the first washing after the fixing bath, will produce this fog. Some papers are less prone to yield grey fog under these conditions, while others are particularly prone to produce it.

Yellowness and grey-brown fog are the two discolorations now to be considered. The two are clearly distinguished in most cases, but for those who have only suffered from one or the other, a test which I will give will suffice to make the distinction clear. The yellowness is a development stain. It arises from the precipitation of brown products of oxidation in the developer into the film of the paper during development. This stain will be more readily produced in proportion to—

- (1) The age of the developer.
- (2) The duration of development.
- (3) The rapidity of the particular developer in oxidising.
- (4) Exposure to the air during the development.
- (5) The sensitiveness of the film to coloration.

The statement in regard to the last item I can justify by the fact that many papers give the stain continually, unless very short development and very fresh developers are employed. Other papers are discoloured by amidol, but not by metol or hydroquinone developers. Again, most papers show staining, any, only later, on inspection by daylight, but a few yield visibly at an early stage. This yellowing is undoubtedly sensitive to light. It can, for example, be latent, and be rendered visible later by an intensifying action of light.

The grey-brown discoloration is a sulphur stain, and quite distinct from the others. This leads me to suggest a method of working, and I will first deal with discoloration (c).

The acid fixing bath stops development just the same as the "dead stops," sometimes used with bromide and gaslight papers. It acts as a clearing bath, as well as a fixing bath, to clear any development stains which are not in some way soluble in plain hypo. But it has the possibility of damage within it, owing to the addition of an acid to hyposulphite soda, and the liability to this danger is what causes many to recommend a plain hypo bath for bromide and chloro-bromide

work. A plain hypo bath works very well, although not acting as a "dead stop"; the development, therefore, requiring to be stopped early, but the accumulation of developer therein may lead to stain soon afterwards. The plain hypo bath only works well if the developer is one of the non-staining kind, and if the conditions of development are correct. It would, therefore, be better to learn how to make a safe acid fixing bath, and to use it when we desire it. The danger is that any strong acid is liable to decompose the hypo and deposit sulphur. Now, to avoid the danger. Great men—men of unquestioned greatness in chemical and photographic knowledge—have put forward a bath made with sulphuric acid. This, however, I think is not wise. I think that sulphuric acid is about the worst acid to effect this splitting-up tendency; lactic acetic acid is a far better acid for this purpose, while sulphurous acid is supposed not to act in this way on a hypo bath, and, as far as can be seen, this acid may safely be used. The danger of decomposing the hypo and depositing sulphur by the strong acid may generally be obviated or minimised by dissolving all the constituents of the formula separately, and then adding the acid constituent slowly. It is dangerous with any strong acid to pour it into a very strong solution of hypo, particularly one in which there are any particles of hypo still undissolved by water. In my experience, the safest way—in an absolutely safe way, in fact—is to import a salt, super-saturated with the acid, into the bath. The cheapest salt of this kind is sodium bisulphite. If sulphurous acid is added in the form of bisulphite of soda (a salt containing the acid in its free form) it is so safe from the decomposing tendency that many firms are selling a dry mixture of the hypo, and the bisulphite, to be, of course, dissolved in water together. For plates, the best fixing bath is a solution of hypo in water. An acid bath is, however, useful to prevent development stain of hypo, and to stop the development. For negative films, an acid bath is at no time advisable, owing to its great tendency to separate the gelatine from the support; although a solution made up in alum might be expected to obviate this. But negative papers need an acid fixing bath to avoid a trace of stain on the paper support, the meta-bisulphite bath being a particularly good one for these paper films. Bromide papers particularly need this bath, as, their effect being positive, and the image being viewed against the white paper, the presence of any vestige of stain is objectionable. A "toned" paper, of coloured base, is permissible, because the degree and nature of the coloration is under control, as a fortuitous colour cannot be.

Now we turn to the yellowness which has its origin in development, and not in the action of the hypo or acid-hypo. Given the causes, the remedy is clear. Use a developer which does not readily oxidise—like metol-hydroquinone, or, if a more active developer is desired, even though it be constitutionally more addicted to stain, let it be freshly made and quickly used. Let all developers having a tendency to stain have a sufficiency of bisulphite, to keep the products of oxidation suspended, and not precipitated in the film; and add the reducer dry at the time of use, or only filter through cotton wool when about to use. Let the exposure be sufficient, so that the immersion of the developer need not be excessively prolonged. Avoid exposing the print unduly to the action of the air. Mr. John Tallia's view is that yellowish whites are most often caused by repeatedly taking the prints out of the developer, to examine them during development, thus giving rise to oxidation of the developer, on the gelatine film being brought into contact with the air. Work with plenty of light, so that the prints may be properly examined without their removal from the developer. Let the fixing bath be fresh—that is to say, free from developer discoloration.

With regard to the greying discoloration. Knowing that exposure to actinic light is the cause of greying, it is clear

that the greying will be avoided if the operator tests the light of the window used when changing the paper; also the developing light; keeps all white light from the prints while fixing; keeps them free from white light for a few minutes in the first washing water—in fact, until the soluble salt is washed out into the water. Of course, imperfect fixing should be guarded against, although three minutes has been said to be sufficient for effecting the fixation of bromide prints. Do not blame the products of the manufacturers. As a rule, I think, we may take it that the plates, films, and papers obtainable nowadays are properly made and correct; but sometimes they are fogged by light at the factory; and some of the rapid papers made abroad, and sent over to this country by sea, come "ripened" and most sensitive, even in the high lights of the image. There are those who never find white light fogging their prints in the fixing bath; indeed, several people disbelieve that the fixed print can fog. We will deal with this fog for a moment. Mr. Horsley Hinton says of plates that they can be washed, and then fixed in a white light freely; but he does not specify any particular make of plates or paper, and the statement appears to be too general. Mr. Arthur W. McCurdy, of the Franklin Institute, Philadelphia, said just the same thing, and that thorough washing before fixing is a *sine qua non*. But here, again, no particular kind of plate is mentioned. Mr. V. C. Warner confirmed these statements. He used Bradley's "Extra Speed" plates; and he concludes (1) a plate or film, washed free from reducing agent used in developing, may be fixed as well in light as in dark, and at the convenience of the operator; (2) before fixing, it can be exposed to bright, white light, then redeveloped—in a weaker developer, till the entire surface is veiled—with no reduction of detail, only more printing density; and the result will be free from fog. In my opinion, however, all this is too general, for all these gentlemen lay down one statement for all films; but is this statement correct? Some emulsions will certainly fog under the conditions mentioned. Lumière plates, for instance, could not be taken into white light immediately after development without fogging; and the same is the case, I believe, with Austin Edwards' and Ensign films. And so also in the case of bromide paper; all bromide prints will fog if exposed to white light before fixation, and several will fog in the fixing bath, and until the soluble salt is dissolved out in the first washing water. Associated with this salt may possibly be some unaltered, or only slightly altered, yellow silver bromide.

A test to distinguish the sulphur stain from development stain is as follows:—Mercuric chloride—ordinary bleaching solution for intensification—will soon affect the yellow stain, which contains no sulphur, turning the stain white in a short time; but the grey-brown sulphur fog or veil is only very slowly affected by mercury, which does not entirely bleach it, but only makes it lighter. The yellow development stain is a compound of oxide of silver with the product of oxidation in the developer. This compound is insoluble in plain hypo. Under certain circumstances this yellow stain may pass, by the action of hypo, into a sulphide which is insoluble. Both these facts are arguments for an acid fixing bath.

The old-established idea of the reaction of the crowded fixing bath is possibly an incorrect one. It is, perhaps, incorrect to say that all silver haloid passes into a double silver salt. Some part of the haloid may be but triflingly modified and remain, till perfect fixation is finished, in nearly its original state.

And now to speak of developers that tend to stain. It would almost seem as if the tendency to give yellowish stain were in some way associated with the amido radical in the constitution. Amidol is found to readily stain, and several others containing NH_2 in their formula are also prone to stain. Those of the new synthetic reducing compounds which have not the NH_2 radical are free from this tendency (the one exception, as far as I know, being pyrogallol). I throw this out merely as a query

for the learned to answer. It is, of course, beyond the province of a mere worker like myself.

The acid hypo bath is used for plates, to avoid blistering, and also to prevent stains in the film, chiefly because of the use of the alkaline carbonates, or because the concentration of new developers (caused by use of large quantities of sodium sulphite in conjunction with alkaline carbonates) tends to blister.

The sulphur difficulty is a great difficulty, as much in the acid-fixing bath as in the notorious combined toning and fixing bath. Theoretically, the addition of acid to the hypo must produce the liberation of sulphur; an acid salt should, of course, act likewise. This formation is readily observed by adding in a test tube a crystal of citric acid to some hypo solution, and then gently heating it, when a white, curdy precipitate will gradually appear. If only a small quantity of acid be present, milkiness ensues, and the precipitate separates more slowly. The sulphur difficulty is much delayed (but not, I believe, prevented, when an old solution is used) if the acid and the hypo are separately dissolved, allowed to cool, and slowly added together, although a long delay before use seems to make the action very great. When alum is used with hypo many dangers arise, the separation of sulphur being almost inevitable.

With silver present, the sulphur precipitated in the film is very ready to form silver sulphide. With interrupted fixation, some of the sensitive salts may be left in to fade, discolour, or to perform a multitude of reactions. But acid directly added to alum and hypo solutions may effect many changes, good or bad. The danger is that a strongly acid substance is liable to decompose the hypo, liberating sulphuretted hydrogen, and depositing sulphur; or it will liberate hypo-sulphurous acid, which splits up into sulphurous acid and sulphur. But the process of the deposition of sulphur is very slow; while the presence of the sulphurous acid, as well as the hypo-sulphurous, and the excess of the hyposulphite of soda, keeps the bath useful and the prints clean. The process seems to me to be that, when an acid-hypo bath is used, it will eventually act in depositing sulphur. This process, however, is extremely slow—so slow, indeed, that we may ignore it in the early stages of the bath. That is why, in using the alum-hypo bath for sepia toning, it acts best when old, and worst when quite new. Conversely, it acts as an acid-fixing bath best when new and worst when old.

A safe acid bath may be made according to this formula:—

Hypsulphite of soda	4 parts.
Metabisulphite of potash.....	1 part.
Water	20 parts.

But the metabisulphite is costly, and the same result is obtained with bisulphite of soda. For plates we may have two stock solutions, made as follows:—

I. Hypsulphite of soda	1 lb.
Water	50 ozs.

This should be well dissolved: for, if we are going to have any danger at all it is most likely to occur when the hypsulphite is not in perfect solution.

II. Bisulphite of soda	4 ozs.
Water	20 ozs.

This should be kept in a stoppered "Winchester." For use, one bulk of II should be added to ten times the quantity of I. For papers—bromide, etc.—dilute with from 25 to 50 per cent. of water. If using amidol, add it dry at the time of use to avoid stain. Another way is to dissolve it in part of the water used, and filter the solution with the other dissolved constituents. An excellent formula for good black prints is:—

Sulphite of soda	1½ oz.
Bromide of potassium	15 grains.
Water	15 ozs.
Amidol (added at time of use)	60 grains.
(Or 4 grains to 1 oz.)	

This will work all the better if the sulphite is also fresh dissolved.

Another formula for soft grey prints is:—

Sulphite of soda	3 ozs.
Water	80 ozs.
Metabisulphite of potash	12 grains.
Bromide of potassium	8 grains.

Filter 1 oz. bottle amidol into this by part of the solution.

A. G. FIELD.

YACHTING PHOTOGRAPHY.

[A paper read before the Edinburgh Photographic Society.]

AMONG the many sports with which photography is combined there is none, I consider, which lends itself to the use of the camera so much as yachting. Be he the keen racing enthusiast or the easy-going cruising man, he is always tempted to have a record of his favourite pastime. In racing, the manoeuvres a start, the neck-and-neck hammer up to windward sometimes fairly enveloped in water, the roundings of the marks, the run home with spinnaker, and the finish where the hulls of the boats sometimes scarcely be seen for the amount of white canvas crowded on to the towering spars all appeal to the photographer while it would be difficult for the latter, from the time he comes yawning up the hatchway to look round among the morning mists and the dingy surroundings of some busy harbour, until he for a change drops anchor at sunset in a quiet little peaceful bay, far from the madding crowd, to resist the many appeals of the ever-changing moods of nature, the range of scenery, and the many both exciting and humorous events which take place in a day on the sea. On thinking over how I should treat my subject, I am afraid that I cannot give it justice here. I would have no difficulty in addressing a yachting audience, as to be technical would be making everything plain; but to be so here would, I think, be making myself unintelligible to most. However, I will go over as simply as possible a few points which I think would be of assistance to any one wishing to have yachting pictures.

To begin with, I wonder if I should, in an inland town like this, take for granted that all my listeners know how a yacht is rigged, and whether for the benefit of a few I should give a short description of one. As it would be rather difficult to do so very fully without wearying one or two of the "would-be" nautical men present, I just give in a few lines the remainder of a novice making his first visit to a yacht. The yacht was yawl-rigged. The account, I may say, is taken from the "Cruise of the Folly":—"It boasted of two masts, and there were other smaller pieces of wood projecting horizontally from each end. I was inclined to complain of this arrangement as it made it difficult to distinguish between the head and tail of the vessel till it began to move; but if you bear in mind that the one in the bows is called the bowsprit and the other the one the bumpkin, there is no real difficulty, at least not to the experienced eye. The mainmast rose out of the front part of the deck, and supported four sails, two in front and two in rear. The ones in front were triangular in shape, and extended between the mast and the bowsprit, the one before being called the jib and the one behind the foresail. The sails at the base of the mast consisted of the mainsail, a huge trapezium, and another triangle on top called the topsail, a word whose etymology requires little or no explanation. The mainsail, it is important to note, was stretched out on two spars, the gaff above and the boom below; and one of the chief perils of navigation on board a yawl arises from the unpleasant habit the boom has of swinging over from one side of the vessel to the other, thereby endangering the lives of persons who may be seated quietly smoking or playing cards on the deck. The second mast, known by the mysterious name of the mizzen, was planted at the extreme rear, and carried a small edit

the mainsail. The sail was attached by a rope to the end of the bumpkin, and was thus made to serve as an artificial extension of the real length of the yawl. When it is borne in mind that the allowance which one boat has to give another in a race depends largely on its length, it will be seen that this contrivance is not quite so childlike as it may appear at first sight." I am not sure that this description makes things very simple, but it at least shows where the different sails go in case I should mention them later on. Well, I think it would be a good plan if I gave here a few of the errors and mistakes which I first made when I started photography.

Some years ago, when I was owner of a smart little seven-footer, of which I naturally thought a great deal of, a friend came to stay with me for a few days, and I was delighted to find he was a photographer, so that now I thought I would have no difficulty in getting photographs of the boat. He was with us about a week. I spent a considerable time each day idling past the slip of the pier on which my friend stood holding his wonderful box at us. His evenings were spent in one of my rooms shut up by himself, as I thought, doing nothing but messing the furniture; but, to my great delight, one morning he presented me with a photograph of the yacht. It was splendid! I did not mind much if she was up in a corner, or if a bit of her topmast was cut away, or her bowsprit looking very short. I could recognise her quite well—photography seemed a splendid thing—I must go in for it; and, as I wanted to dispose of his camera (from what I learned afterwards I was not surprised at this), I became a ready purchaser. It was a beautiful instrument, made of mahogany and brightly finished; it had a small hole in front with a neat little lens (none of the great, big, ugly pieces of round glass you see nowadays), and had a spring shutter which went off like a trap, which I thought would make the photographing of yachts going at full speed an easy matter. I had only to get the camera to be fully equipped for taking pictures. I went to a dealer (who I thought a great stupid); I wanted very quick plates so as to take yachts in motion, and he would try to sell me slow ones, saying that they were plenty quick enough for my work; but as I could see he did not know anything about yachting I took the fastest I could get. I then gave up an afternoon's sailing to get a few pictures of the yachts as they came into the harbour. I wanted a good position where I could be perfectly steady, so that at first I would not be troubled with the camera being moved during exposure. I went to the pier and got myself planted against one of the big round pile-heads on which the ropes are attached to moor ships alongside the quay. This I found gave me a nice space between two of the piles, so I set the shutter and waited for the first yacht to come out. I was getting her nicely centred on the finding, and seeing the camera round as she came along. I was in luck—it would be a splendid picture; when I was suddenly startled by a rough voice from aboard the ship alongside the quay shouting out, "Let go that rope!" This startled me and spoiled my exposure. It was in no good humour that I told the man "I wasn't touching his rope"; but as my answer, instead of appeasing him, seemed to make him very angry, I went further along the pier, where I got an opportunity of posing my plates. After I got them developed I found that I put bits of them together I might be able to make up a picture out of the lot. I had not a whole yacht on any of them—I had a topsail, another a bowsprit, another a mainsail, and so on. I may also say that the results were very flat and dull, so I blamed the plates. I felt sure they were too slow; and I am aware that they were much too quick for working at full aperture of the lens. I was a little disappointed at the results, so gave it up until the opening cruise came off, when we were to have a photographer down to photograph the boat, and when I thought I would get a few hints, and that after seeing his way of working I would get on better. He set

up a stand camera on the breakwater, got one of the yachts to sail past to focus on, then told the rest they were all to pass at the same distance from him, which he estimated at thirty feet. From my experience of judging distance on water I put it down at eighty feet; but I am sure that every one, and especially beginners, will find it much more difficult to judge distances on water than on land. As each yacht passed he made an exposure, and when they were all taken told us he would send us prints in a few days. I may say we did not get the prints, but I saw the negatives, and I must say they did not help me much, although his results were different from my own. Where I had only got a little bit of a boat, he had got all but the little bit. I counted his mode of working, and was no good, and henceforth I condemned stand cameras for this work. I persevered after this, but decided my failures were due to the camera. Now, I am inclined to think that some people will put it down to my fault, as we are occasionally told that these cheap cameras will do as good work as the very expensive ones. However, I launched into expense, got a camera with a good lens, a varied speed-shutter, and a good finder, and after this my failures began to get a little less frequent. The principal difficulties I had were focussing and getting my subject all on the plate. With a yacht coming tearing towards me I found it a little difficult to reckon the proper distance to set the focussing scale, and also with the small finders to get everything on the plate and have the horizon at the proper angle. When I began to get accustomed to getting over these difficulties, a box form of magazine camera I found a handy and convenient instrument. It stood a lot of knocking about, was always set ready for use, and a little salt water did not harm it much; but it had several drawbacks for serious work. From my experience the essentials of a camera for this work is one with which you can see and focus your subject up to the moment of exposure, and which will allow of this being done even when using a long focus lens, such as the single combination of the ordinary lens. With a short focus lens, such as a 5 in. on a quarter-plate, or a 6 in. on a 5 by 4 plate, when taking a boat coming bow on, it makes the different sails seem out of proper proportion to each other, the size of the jib appearing too large for the size of the mainsail. Also it is not always easy or convenient to get sufficiently near a boat to show her a fair size on the plate with lenses of the focus just mentioned. I have found an 8 in. lens very suitable for a 5 by 4 plate, and the single combination of 16 in. focus gives a good-sized picture even when working a considerable distance from your object. The lens should be an anastigmat working at a fairly large aperture. The necessity of this will be seen later when I come to speak of the plates used. Using long-focus wide-aperture lenses one will readily see the need of being able to focus by the finder up to the time of exposure. A focal plane shutter is also a necessity. In some of the present-day manuals you will find it stated that in taking a vessel going in the opposite direction from which you are sailing an exposure of 1-75th of a second is sufficient. This is all right if you are photographing from an Atlantic liner which goes along comparatively steady, but if you are working from a lively little half-rater—that is one of the smallest class of yacht—you will find sometimes that 1-200th part of a second is none too quick. In this case it is not the speed of the vessel that has to be considered so much as the sharp, jerky motion of the boat you are on. There is another fitting to the camera which I found of the greatest convenience—that is a reversing back which will allow of almost instantaneous changing of the plate-holder from a horizontal to an upright position, or vice versa, after the slide has been drawn out. Of course I admit that all these requirements in a camera are apt to make it rather bulky, but I do not consider this a disadvantage, as you do not have to carry it for a mile or two between each exposure as when hunting for pictures on land. A movement

which I would like to have on my camera, and which I do not see any way of accomplishing as yet, owing to the focal plane shutter, is a method of changing the plates as quickly as can be done in a magazine camera. As to the best plates to be used. After a great many trials with various makes of plates I may say that Isochromatic plates are essential; and owing to, especially in fine weather, the intensity of illumination, the preponderance of the blue rays and the delicate tone values, a screen is absolutely necessary. Where rapid movement has to be taken into account, a light screen which doubles the exposure can be used; but in cases where a slow exposure can be given, a screen which increases the exposure four or five times is to be preferred. For instance, in good light, F. 11 with a hundredth part of a second and a light screen, I have found to be a very ordinary exposure; but when using a darker screen the benefit of a large aperture lens will be very apparent.

Backed plates must be used, as it is quite hopeless to expect to get the fine wire rigging of a yacht against a light blue sky otherwise. Also, without backing you will often have the outline of the white sails under the same conditions—very faint and indefinite. With regard to development, we often hear amateurs complain about not being able to get sufficient density; but in marine work the great thing is to guard against getting too much. Isochromatic plates with any subject give density very readily, and this is very much accentuated when using them on the sea. Hydrokinone developer alone should be avoided, but for those who will have a clean, non-staining developer, hydrokinone with eikonogen will be found fairly satisfactory. Pyro soda I consider to be the best, but the ordinary formulæ given with plates should be slightly altered, the quantity of pyro being reduced and more water added. Preference should be given to a two-solution developer, such as mentioned, which will give power and latitude in development. Thin, well-graduated negatives will be found the best for getting good results on the most modern of our printing papers, and also for enlarging and lantern-slide making. I may now say that I have never attempted to treat my yacht photography in the manner which now by some seems to be counted as pictorial. By this I refer to the smudgy, out-of-focus, muddy-looking results which we have occasionally seen medalled at our exhibition.

A friend of mine who seems to make this his aim came out with me one day for a sail, and I think he photographed every yacht we passed, apparently with the view of teaching me afterwards how to make "pictures." He sent one of the so-called "pictures" to the owner of one of the yachts, whom I afterwards heard described it in the following manner: "To begin with, my fine new sails were a dirty brown, as if they had been in use on a fishing-boat for ten years; my nice three-eighth of an inch galvanised steel wire stays were like a three-inch coir rope, and looked more like a trawler's tow-rope; my newly-scraped and varnished spars were like rough pit-props with the bark still on them; the spotless, clean decks were like a dredger's platform; the sea was the colour of a ploughed field; and the whole affair, instead of leading you to believe it was taken on a bright summer day, had every appearance of a dark, dull, muggy day in November." My friend told me afterwards that he considered it the finest thing he had done, and wanted to have a few more opportunities of yacht photography. I am afraid I gave him very little encouragement, although I took him another trip shortly afterwards. He had heard me saying what a curious sort of picture it made to take a view of the deck from the cross-trees when sailing, and as this seemed a little out of the ordinary, he would have a try at it. Well, he got a fine opportunity; it turned out a splendid day, with a nice fresh breeze, so we paid off before the wind to have the boat as steady as possible. I may mention he was no sailor, and I rather disliked the idea of him going aloft. However, as he insisted on doing it, I gave way to his wishes, and saw

him start on his upward journey. I often laugh when I call memory that fearful clamber upwards. He did make a journey of it. However, in the end, with the aid of his hand, arms, legs, neck, teeth, and eyebrows, he managed to get safely seated on the cross-trees. We then sent up his camera to him on signal halyards. He exposed a plate, only one—he seemed to be always sure of his results—and sent down the camera again. He then started on his downward trip, but I wasn't so frightened for him at that. He got safely past the throat halyard block and the jaws of the gaff, and was starting to come down the mast-hoops, when he seemed to "lose his head," slipped, came down on the deck all of a heap. I rushed forward expecting a broken arm at the very least; but when I asked him if he was hurt I was greatly relieved to hear him cheerfully reply, "Not a bit; it's all right; I was coming down at a rate." I may say that plate, for what reason I never heard did not turn out well, and I have never been able to persuade him to have another try at it.

I would advise amateur photographers not to be too ready to accept invitations to go out for a sail with a view to photography. The trip is not always an enjoyable one to a shore man, and is usually something like this. You get aboard and find the crew has by some error not got the owner's message to have the yacht ready, and you spend half an hour at hard work hauling at ropes, etc., and by the time the sails are up you look at your fine soft hands to see how much of the skin is still left on them. The moorings are slipped, and as the yacht glides gently out of the harbour you lay yourself on the deck under a blazing sun, with just sufficient wind to keep the heat from becoming uncomfortable, and begin to think life is well worth living. But this does not last long. As you get further out the breeze freshens, the deck takes a different angle, and you have to get perched up in a corner clinging on to a rope to prevent yourself from slipping down to the lee side, which, to say the least of it, is not very dry. At last your host seems to brighten up, says, "Now she is going, and, after a little persuasion, you are bundled into the dingy which has been towing astern. You find she is not very inviting—all wet, and most unsteady. You are left in her, and what you think to be an hour, while the yacht sails past several times. Every time she passes you attempt to stand upright in this "cockle-shell," holding on to your camera as you never did before; your legs jammed up between some of the seats so that when an extra jerk comes and puts you off your balance you will be sure to collapse, not into the water over the side, but into the by no means clean water in the bottom of the boat. You always seem to prefer the latter. After you have exposed all your plates, the yacht "heaves to," you get aboard again, but your pleasure seems to be at an end; for "convalescence" you have to sit close to the side of the yacht where the spray is drenching you to the skin; you feel cold and miserable, the salt water is nipping your poor, skinned fingers, and put yachting down as the most idiotic sport you have tried, and, as a rule, are very glad when the trip is finished, and you once more set foot on terra firma.

Of course there are exceptions to the foregoing. Where your host does not wish a photograph of his own boat, and if you are one which is easily handled, it is often a great treat to sail along to leeward of another yacht; and if the two yachts are about the same turn of speed, it gives you ample opportunity for making several exposures, with plenty of time to change plates and study the position and lighting. The ideal for the yacht photographer is a smart little steam or motor launch which will do her eight to ten knots an hour. This makes matters very pleasant. At a regatta you can go from one race to another from the lee mark to the weather mark, and have an excellent choice of position. If you have to content yourself with a position on a regatta steamer there are one or two points worth remembering. Firstly, a long-focus lens is an absolute necessity

the steamer usually gives the yachts a wide berth. You will occasionally come across a well-managed vessel which will take up a nice position just to leeward of the weather mark, and which will steam up to leeward of a batch of yachts apparently just to give the photographers a chance; but sometimes they seem to go on the old lines that "Distance lends enchantment to the view," when you find that a telescope will be much better company than a camera. When making exposures keep as nearly amidships as possible, as the vibration, especially on the light paddle steamers on the Clyde, makes photography at the bow or stern almost an impossibility. Another point I might emphasise is to keep as low down in the vessel as possible. The paddle-box or the bridge gives a fine commanding view, but the lower deck is much to be preferred. The former are much too high, with the result that when you have to point the camera downwards to get a yacht in the centre of the plate, the horizon line comes much too high on the picture, giving a very unnatural-looking result. As to the position in which to photograph a yacht, the most popular view is from the lee side. When a boat is close-hauled—that is, going as near to the wind as possible—she is best taken from the lee bow; but it should be noticed that she has plenty of "way" on at the time of exposure, as, if taken, say, immediately after "going about," or, to put it simpler, going from one tack to another, she will be "lying down," but have no appearance of going through the water. When reaching with a beam wind and the sheets "eased off," a view from right abeam or a little abaft of it makes a pleasing picture, giving, as it does, a fine idea of the lifting power of the sails. Another position which makes a nice view when the sheets are eased is from the lee quarter; but some difficulty will at first be found in catching just the proper angle at which to make the exposure. If taken from too far aft the head sails will seem mere narrow strips, while what is required is that they should all have a good appearance of drawing well and doing their work properly. I may say that it takes a modern boat with good setting sails to show up well in the latter position—the "old crocks," with badly-stretched, baggy sails, usually cutting a very poor figure, this being a view which shows up these defects to the greatest extent. In photographing yachts the operator must be able to judge distance accurately, and be prompt in using his camera, as the slightest hesitation usually means the loss of a good picture.

J. F. DUTHIE.

INTERNATIONAL Printing Exhibition.—At the Agricultural Hall on Saturday afternoon last an International Exhibition of the Printing, Stationery, and Allied Trades, surpassing all its predecessors, was opened by Sir James Henderson, of Belfast. It is some six or seven years since a similar exhibition was held, and even the important Caxton Celebration Exhibition of 1851 has been out-distanced by the present event. Under the able organisation of Mr. F. W. Bridges, the trades supported the movement to a remarkable degree, over three hundred exhibitors taking part and showing no less than five hundred different machines, of which one hundred were in operation. Besides this, numerous displays of art stationery, picture postcards, and commercial appliances were on view, as well as an historical loan collection, including Japanese wood-cut book illustrations of the notable periods. Labour-saving appliances in all departments are strikingly apparent, and no lack of energy or money has been spared to place the British trader in the foremost position. There are several mechanisms for automatically feeding sheets of paper into machines, a subject to which much thought has been given of late years. The printing of three colours in one process as against three is also demonstrated, while the substitution of aluminium plates for the lithographer's stone has made a marked advance. One of the chief advantages of the latter is that rotary presses can be utilised, to say nothing of the saving of weight and storage room. A complete model printing office is laid down by Messrs. John Haddon and Co. The London Stereoscopic Company are represented with some beautiful collotype printing and photography, while Messrs. Raphael Tuck and Sons are among the foremost with picture postcards, etc. Altogether the exhibition can be said to be a most thorough one and decidedly well arranged. It will remain open for a fortnight.

Exhibition.

THE CAPE TOWN PHOTOGRAPHIC SOCIETY.

It is now some years since the Cape Town Photographic Society held an exhibition. The years that have elapsed since the last exhibition have been very fruitful, and this year the exhibition is one of great interest. The "South African News," in reviewing the exhibition, says:—The exhibition of the Cape Town Photographic Society was formally opened in the School of Art, Queen Victoria Street, on April 4 by his Excellency the Governor, Sir Walter Hely-Hutchinson, and the show is a great success in every way. There are two sections in the exhibition. One is open to competitors of any photographic society in South Africa, and the other is open to members of any photographic society in the world. In addition to this, there is a loan exhibition of photographs from the Royal Photographic Society of Great Britain and also from the North Middlesex Photographic Society.

The "Cecil Rhodes' Memorial Medal" (gold) is the highest distinction that can be conferred by the Cape Town Photographic Society. It is given—irrespective of class or subject—for the most artistic picture, and has been awarded to Mr. F. J. Mortimer, of the Southsea Photographic Society, for a seascape. Mr. Mortimer has won many distinctions, and this beautiful seascape of his is a most finished and artistic production. "The Deep's Unrest," by Mr. J. P. Edwards (C.T.P.S.), takes the second place among the seascapes, and to it a silver medal is awarded. The stormy sea and dark clouds are in sharp contrast to the light which pours down between the broken clouds. The other seascapes which have been specially commended are "The Frothy Main," by H. W. Schonegevel (C.T.P.S.), "An Evening Zephyr," by F. A. Joyner, South Australian Photographic Society, and "After the Storm," by E. J. Steer (C.T.P.S.). This last is a very beautiful piece of work, and depicts a background of calm sea—though the breakers are still dashing upon the rocks on its margin. Among the landscapes open to competitors of any society, "A Pathway to the Sea," by Charles R. Pancoast, of the Photographic Society of Philadelphia, is the best, and to it has been awarded a silver medal. It is a beautiful piece of work. The light over the sea is very clear, and every detail of the bush on either side of the pathway is wonderfully distinct. "Homewards," by E. Naude (C.T.P.S.), has received an extra bronze medal. It is a representation of cattle, grazing on their slow progress homewards. An extra bronze medal has also been awarded for "Dawn," by Sydney Taylor (C.T.P.S.). Commendation has been given to "Solitude," by E. Naude (C.T.P.S.), and to "The Rist River," by H. W. Schonegevel (C.T.P.S.). This latter is a typical African scene, in which the river winds its way between high rocks. "Barren Hills and Fertile Valleys," by E. J. Steer (C.T.P.S.), and "Afternoon in the Berkshires," by C. R. Pancoast, Philadelphia, are also commended.

In the genre or figure studies, the silver medal is awarded to "Reflections," by Robert Ayton (C.T.P.S.). The figure of a girl sitting among soft shadows is the theme. Extra bronze medals have been given for "Waiting and Watching," by F. A. Joyner, South Australian Photographic Society, and for "The Fisher Maid," by G. Campbell Dickson (C.T.P.S.). The fishermaid makes a particularly charming picture, sitting on the rocks with her bare feet thrust into the sand. "The Portrait of a Lady," by G. Greene (C.T.P.S.), is commended. The detail of this is particularly good. Every thread of the lace can be discerned, but from an artistic point of view the face is over-wrinkled. The effect of age might be given without the innumerable lines that veil the expression. "An Africander Blossom," by A. Elliott (C.T.P.S.), which is also commended, is a vigorous life-like portrait. "Art or Nature?" by A. Keyzer (C.T.P.S.), has won commendation too. For architecture, the silver medal has been withheld. The bronze medal has been awarded for "Black Adden Crypt," by J. Campbell Dickson (C.T.P.S.). "Wells Cathedral," by George Greene (C.T.P.S.), and "Interior of Stainsborough Hall, Yorks," by John W. Young, of the Sheffield Optical Society, are commended. The detail in the "Interior of Stainsborough Hall" is remarkably good. The pattern on the ceiling and the pictures on the walls are easily discernible. In the class devoted to flowers and plants, the silver medal has been awarded for "Roses," by J. P. Edwards (C.T.P.S.). The roses are beautifully grouped, and stand out well. "Gladiolus," by E. J.

Steer, is a very dainty and artistic piece of work, and has been commended. For home life no silver medal has been awarded. The bronze medal falls to "Fireside Gossip," by Sydney Taylor, and "Christmas Stories," by J. P. Edwards (C.T.P.S.), is commended. The silver medal for lantern slides goes to "La Grosse Horloge, Rouen," by A. Bailey, Leicester Photographic Society, and the silver medal for stereoscopic transparencies to "Crypt, Battle Abbey," by Harry Wormleighton, Leicester, and Leicestershire Photographic Society. In the stereoscopic paper prints, "Ruins of Fortifications," by A. J. Fuller (C.T.P.S.), wins the silver medal, and set No. 3, by W. S. Wedd, South Australian Photographic Society, is highly commended. Set No. 8, by J. Gazard, South Australian Photographic Society, is also commended.

In examining the section of the Exhibition that is devoted to South African work only, the onlooker is struck by the effect that the clear atmosphere of South Africa has on photography. The strong light and clear air bring out all details with amazing distinctness, and at the same time make it most difficult to get a correct perspective.

The silver medal given for the most artistic picture in this section has been awarded to Mr. J. P. Edwards (C.T.P.S.) for "The Deep's Unrest." Among landscapes, Mr. E. Naude's "Homewards" occupies the first place, and commendations are given to the following:—"The Fall of Day," J. P. Edwards; "Cape Town from Table Mountain," T. Mowbray Turquand; "Bare Slopes were Chasing Shadows skim," E. J. Steer; "A Transvaal Pastoral," J. S. Dunn.

In the seascapes (South African) the distinctions are as follows:—First place, No. 127, "The Deep's Unrest," by J. P. Edwards, who takes the silver medal in this section; extra bronze medal to No. 113, "The Frothy Main," by H. W. Schonegevel, C.T.P.S.; commended, No. 255, "Table Bay, Early Morning," by Dr. G. F. M. Nellen, C.T.P.S.; No. 114, "The Song of the Ocean," by G. Campbell Dickson, C.T.P.S.; No. 128, "Lost in the Solemnity," by A. J. Fuller, C.T.P.S. In old Cape architecture and antiquities no medal has been awarded, but the "Entrance to the Castle," by E. J. Steer (C.T.P.S.), and "Welgelegen," by P. J. Edwards (C.T.P.S.) are commended.

The figure studies (typical South African) are particularly interesting. The following distinctions have been earned in this class:—Bronze medal, No. 283, "Kleintje," by A. Elliott, C.T.P.S.; highly commended, No. 273, "Malay Priests," by E. J. Steer, C.T.P.S.; commended, No. 275, "A Cape Cottager," by P. J. Edwards, C.T.P.S.; No. 286, "Primitive Conveyance, Knysna Heads," by W. Baker, C.T.P.S. "De Kleintje" is a black boy standing in the bush. The "Malay Priests" is a very characteristic picture. The strong light and shadow and the hot atmosphere that seems to surround the figures and to envelope the glimpses of Devil's Peak that form the background, are eminently characteristic of South Africa.

For child life the medal is awarded to the "Dreamland" of Mr. J. P. Edwards, and commendations are accorded to "A Happy Trio," by A. Keyser, and to "Florrie," by Sydney Taylor. Among the African flora Mr. E. J. Steer's "Gladiolus" is commended. In the class devoted to river, pool or vlei, the following distinctions have been earned:—Bronze medal, No. 326, "From Yonder Mist-capped Hills," by E. Naude, C.T.P.S.; commended, No. 361, "To the Woods," by H. R. Brownlees, C.T.P.S.; No. 23, "The Water Mill on the Mooi," by J. S. Dunn, C.T.P.S. No awards have been made for photographs of a South African drawing room or for lantern slides. Among the many beautiful photographs that have not received medals or commendations may be mentioned the pictures of a child, representing the Five Senses, by R. Mumby; Sun-Boy, by J. P. Edwards; Table Mountain from Protea, by E. J. Steer; and Pete, an ex-slave, by E. J. Steer.

It may be questioned whether Viscount Maitland's "At Litlington, Sussex," belongs strictly to the realm of photography, but its value as a work of art cannot be doubted. It is a subdued landscape, and has been so manipulated as to have exactly the effect of an engraving. Throughout the exhibition is one of high merit, and of great interest, as it includes the work of so many different societies.

A copy of No. 1 of the "Half-tone Times" has been forwarded us by Mr. Carl Hentschel. We note that it is also the only number, and its price is ten minutes (of our time). The publication contains much that is bright and witty, and is embellished with many excellent half-tone reproductions. We think possibly Mr. Hentschel may reconsider the matter and produce a second number.

Patent News.

The following applications for patents were made between April and April 23, 1904:—

Plate washer.—No. 8,839. "Print and plate washer for photographic purposes." George Tom Harrison.
Imprinting upon negatives.—No. 9,105. "A process for imprinting matter upon photographic negatives." Complete specification Frederick William Sears.
Shutter release.—No. 9,182. "A new or improved means for releasing photographic shutters and the like." Frederick Pernewley.

FORTHCOMING EXHIBITIONS.

May 11-18.—Plymouth Photographic Society. Hon. Secretary, Wilfred Grist, 105, Old Town Street, Plymouth.
May 16-23.—Photographic Society of Ireland. Hon. Secretary, E. Webb-Smith, care of Royal Dublin Society, Kildare Street, Dublin.
May 24-28.—Devonport Camera Club. Hon. Secretary, A. J. Catford, 78, Charlotte Street, Devonport.
June-October.—Glasgow Photographic Exhibition. Secretary, A. Gallery and Museum, Kelvingrove, Glasgow.
November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.
November 23-26.—Hove Camera Club. Hon. Secretary, A. F. Sargeant, 55, The Drive, Hove.
December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.
December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104 West 101st Street, New York.
December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.
December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

DATE OF THE GENERAL ELECTION.

CONFIDENTIAL COMMUNICATION.
(From the "Half-tone Times.")

THE following important telegrams and letters have passed between us and the Prime Minister:—

10, Downey Street,
April 1, 1904.

To Messrs. Carl Hentschel, Ltd.

Gentlemen,—In considering whether to resign or dissolve Parliament, or what to do, I must be guided in some measure by your preparedness. Are you ready to execute members of our Party—mean their portraits—both for posters and circulars, not to forge the bumptious, unnecessary portrait post-card.

A few of my men are very cross grained. Does that matter? Please wire reply, as I may want to make announcement.

While writing—what would you want to refuse to portrify any of our opponents?—Your obedient servant,

ARTHUR JAMES BALFOUR.

Hentschel's to Balfour (wire): Resign at once. We mean to say we're ready. What's portrify?

Balfour to Hentschel's: Philosophically doubtful about resigning. Let resignation wait. For portrify, see Murray's Dictionary: means make portrait blocks.

Hentschel's to Balfour: C.B. has curiously made us same proposal if we'll refuse portrify men of your side. We're children in these matters. Please advise.

Balfour to Hentschel's: Better settle it by commission.

Hentschel's to Balfour: Surprised and grieved that you should seek commission.

Balfour to Hentschel's: I mean Royal Commission.

Hentschel's to Balfour: Sorry. That's all right now. Since writing have been summoned for furious driving of our dynamos under pressure of customers. Can you interfere discretion magistrates? Greatly appreciate.

No answer.

EDINBURGH PHOTOGRAPHIC SOCIETY'S SURVEY SECTION.

OBJECTS.—I. To make a comprehensive collection of original paintings, engravings, prints, photographs, lantern slides, and illustrations every description of Edinburgh, Leith, and district of the past.

2. To secure permanent photographs (such as by carbon or platinotype process), drawings, etc., of streets, buildings, monuments of Edinburgh, Leith, and district as they now exist, and of all public open spaces in and around the city, and to obtain representations of the civic and social life and customs of the city. It is desirable that two copies of each print should be submitted.

3. Contributions will be received irrespective of size, but it is recommended that photographs should not be smaller than quarter plate nor larger than whole plate.

4. Information regarding the subjects contributed or photographed, where possible, should be sent, along with the contributions, on a card which may be obtained from the secretary of the section, one card to accompany each separate print, etc.

In connection with the reorganising of this section, which was recently decided upon, the Council have resolved:—

I. That an exhibition of prints, maps, plans, etc., contributed to the survey section, be held in the first week of December next; and that medals be awarded in connection therewith.

II. To effect this object, that all members of the society be asked to submit two prints (preferably in platinum or carbon) from any negatives they may have of Edinburgh and district, past and present; or to lend such negatives to the Council to be printed from; or plans, prints, etc., to be copied.

III. In order to carry out this latter recommendation, that an official photographer be appointed whose duty it would be to take prints from all negatives, and copy all plans, etc., accepted by the Council; and that Mr. J. F. Duthie, 13, South St. David Street, be appointed to the office.

In order to preserve continuity with the scheme as originally constituted, Mr. James Burns, the original hon. secretary of the survey section, was appointed hon. secretary. All correspondence regarding the survey, and all contributions, prints, negatives, slides, etc., should be addressed as follows:—Mr. Jas. Burns, Hon. Secretary, Survey Section, Edinburgh Photographic Society, 38, Castle Street, Edinburgh.

The request for two copies of each subject contributed is one members are particularly requested to note, the intention being to use the two copies in making up two sets in albums, one of which would be kept for reference in the Society's Library and the other probably lent to one of the city museums accessible to the public.

With a view of gathering together a complete record past and present of the district between the Castle and Holyrood (both inclusive) as early as possible, contributions relating to that district are gently requested.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—For the meeting on May 16 the S.L.P.S. have been fortunate enough to secure Mr. John Sterry (hon. treasurer R.P.S.), who will lecture on "Controlling Gradation in Bromide Prints and Lantern Slides." As it is rarely possible for Mr. Sterry to give lectures outside the Royal, the committee, feeling this is a unique opportunity for London photographers, have engaged a large hall and sent invitations to the principal London and suburban photographic societies. The committee are anxious to secure a large attendance, and the hon. sec., H. Creighton Beckett, 44, Edith Road, Beckenham, S.E., will be glad to send a ticket to any unattached photographer or to members of societies to whom this may be the best notification.

GLASGOW SOUTHERN PHOTOGRAPHIC ASSOCIATION.—At the third annual general meeting of this association, held on April 26, the following officers were appointed for the year:—President, James M. MacLean; vice-president, R. B. Thomson; honorary treasurer, Edward Grant; honorary secretary, William A. Frame, 28, Bank Street, Hillhead, Glasgow; hon. assistant-secretary, B. Lindsay; council, T. Lawson, W. S. Morren, D. Horn, James Keith, D. Linton, and William H. Wilson; auditors, R. Young and W. Milroy. At a special general meeting held on the same evening it was resolved that the annual subscription be raised to 7s. 6d. and the nomination fee to 5s., from April 1 last. Any person desirous of joining the association can have full information on application to the honorary secretary.

New Apparatus, &c.

The Goerz Anschutz Folding Camera, 1904, Model. Made by C. P. Goerz, 1-6, Holborn Circus, London, E.C.

For the season 1904 a new model of the Goerz-Anschutz Folding Camera has been introduced, in which a focal plane shutter, giving time exposures as well as the fastest instantaneous exposures, replaces the original pattern. The blind of this new shutter contains two apertures; the first, the full width of the plate, will, when allowed to travel across the face of the plate, give an exposure of 1-10th of a second. The shutter can be so set that this aperture will remain open for focussing or long time exposures. By turning a dial at the side of the camera the following exposures are automatically obtained, $\frac{1}{2}$, $\frac{1}{3}$, 1, 2, 3, 4, and 5 seconds. A pneumatic release is used for

discharging the shutter when set for these exposures. When instantaneous exposures shorter than 1-10th of a second are to be made, the first aperture of the blind is wound up, and another portion of the blind with an adjustable slit—the old form of Goerz-Anschutz Focal Plane Shutter—is brought into operation. The special point of interest in the new form of shutter which will probably appeal at once to the user of the camera is the fact that the shutter can be completely wound up with but one turn of the winding screw. The usefulness of this improvement will be at once apparent. The camera in all other respects remains the same as the old pattern. The pull-out front and focussing mount to lens are unchanged. The finish of the complete instrument is perfect. The price has not been altered.

Thornton Pickard Time and Instantaneous Shutter with new Patent Disappearing Cord. Made by the Thornton Pickard Manufacturing Company, Ltd., Altrincham.

Every user of this now familiar type of shutter who has, at one time or the other, experienced the annoyance caused by the string and tassel becoming entangled before or during the exposure, and so spoiling a plate, will welcome the new patented device which the Thornton Pickard Company have introduced this season. The improvement is termed the "Disappearing Cord." After the shutter

has been set, which operation is done in the usual manner by pulling the cord, the winding cord runs back into the shutter, and is re-wound on a spring drum. The advantage of this will be appreciated at once. When the exposure is being made the cord is out of the way, and therefore cannot wrap round the pneumatic release or get caught in the shutter mechanism when photographing in a wind and the exposure spoiled. This device can be fitted to new or old shutters at a reasonable cost, and is well worth the money.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
2 to 7 ..	Kodak Exhibition	Cardiff, Andrews Hall.
6	West London Photo. Society ..	Outdoor Work: Arranging Summer Programme.
9	Southampton Camera Club	Demonstration of Development, Reduction and Intensification, and Toning of Slides and Bromide Paper with "Tabloid" Chemicals. Messrs. Burroughs, Welcome & Co.
9 to 14 ..	Kodak Exhibition	Swansea, Albert Hall.
10	Royal Photographic Society ..	Progress in Enlarging. Mr. Howard Farmer.
10	Nelson Photographic Society ..	Enlarging Demonstration. Mr. F. Pinder.
10	Birmingham Photo. Society ..	An Exhibition of Enlarged Negatives, Transparencies, &c.
11 to 18 ..	Plymouth Photo. Society ..	An Exhibition of Members' Work.
11	Everton Camera Club	Half-day Outing.
11	North Middlesex Photo. Soc. ..	The Life and Work of George Tinworth. Mr. H. Barnard.
12	Everton Camera Club	Half-day Outing.
12	Richmond Camera Club	General Meeting.
12	Camera Club	Annual Dinner.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

APRIL 28.—Mr. Haddon in the chair.—Mr. A. G. Bull, of the Northampton Institute, gave a lecture, entitled "Some Experiments with Tricolour Filters." Slides were exhibited of three-colour negatives, transparencies, and the finished result. Experiments were made showing how the theoretical requirements of the three-colour methods were met in practice, the various filters, and their effect upon the spectrum were explained and illustrated by means of a very ingenious and elaborate projecting apparatus.

The various screens performed their functions of absorption, and transmission of the spectrum, but the photographic plate did not reciprocate properly, hence the results were not always so good as they should be; but the introduction of many new dyes, pinachrome, orthochrome T., ethyl red, etc., had put much more power into the hands of the tricolour worker. Factorial development was a necessity in the production of the three negatives, which must be alike in gradation and density. A cell of solution of quinone was mentioned as a useful addition to the filters, in order to cut off the blue and violet rays not visible to the eye, but which had an effect upon the photographic plate, which was not at all beneficial to the rest of the spectrum.

CAMERA CLUB.

WHEN an observant man has the opportunity of being thrown in with any particular phase of human industry, and has the help of a camera to record his impressions, he is much to be envied. And it is to be feared that most persons who possess such advantages seek their opportunities abroad rather than in their own country. For this reason, Mr. S. W. E. Schrivell, who is a hop grower in Kent, and who gave an admirable lecture descriptive of a hop garden in that favoured county, is to be much commended. He has sought and found much that is picturesque and interesting within the borders of his own domain, and has been able to give a marvellously complete picture of a Kentish hop garden, and all that it contains.

And perhaps there is no place within a short journey of London Bridge that affords a more varied picture of human nature than does a hop garden when the picking season comes round. It is the annual opportunity for hundreds to get away from their usual squalid surroundings at the East End of London, or elsewhere, and spend a time amid healthy conditions in the Kentish wolds, and persons whose ordinary rule of life is to avoid work of any kind, if they can, are not averse from the pleasant toil of picking the fragrant hop blossoms from the bines. The lecturer described every phase of the labour, and explained it all in a racy fashion as he went along, his remarks being illustrated by a first-rate set of lantern slides, which were from negatives, as he explained, by Mr. Cornell, of Tunbridge Wells. These pictures contained some admirable specimens of good grouping, while some of the studies of gipsy life were beyond praise. The lecture was given on the 25th ult., and a cordial vote of thanks

was awarded to Mr. Schrivell as an acknowledgment of its excellence.

On the 28th, the Club was occupied with a very different subject and a large audience assembled to hear Mr. H. Blackwell discuss on psychic photography, in which he is an earnest believer. He stated that he had had many wonderful manifestations of this phase of photography, and that he could present an array of facts and testimony suggesting an enlarged scope for the use of the camera. In recounting some of his own experiences, the lecturer proceeded to give a short history of his subject, which we will endeavour to summarise.

In the year 1851 a photographer named Boursenell, employed in Fleet Street, quarrelled with his partner because so many of the plates he handled were marked with blemishes—curious patches which sometimes took the form of hands or faces. A Miss Houghton, also of London, had similar experiences, and in 1882 published a book called "Chronicles of Spirit Photography," which contained more than fifty reproductions of pictures taken by Mr. Hudson. Other photographers, both in this country and America, reported having obtained similar abnormal appearances on their plates. Dr. A. Wallace, F.R.S., appears to have been the first man of scientific training to testify to the same occurrences, and he spoke in a public lecture room of the reality of these appearances, both on the part of professional and amateur photographers. The same observer gives in his book, "Miracles of Modern Spiritualism," the names of those who had secured these abnormal effects.

Next, Mr. Blackwell referred to the researches of Sir William Crookes, and his successful endeavours to produce on photographic plates portraits of unseen sitters, and quoted from Sir William's book "Researches in Spiritualism," an account of the way in which he, in the old wet plate days, had five cameras at work under the electric light, and secured forty-four negatives, some very good, and others failures.

After quoting from some American authorities, Mr. Blackwell showed on the lantern screen a number of pictures, in the majority of which he was represented as sitting, with shadowy forms by his side. These pictures, he stated, had been selected from a collection of more than four hundred, of which he was the owner, and declared that they had been taken under conditions which gave no negative any suspicion of fraud.

Mr. David Christie Murray, the well known novelist and writer upon philosophical subjects, who occupied the chair, said they had all been interested by Mr. Blackwell's discourse; but he did not think anything in the way of evidence of the reality of these appearances. One could accept the personal dictum of any man upon a subject of this kind, and he would say it without meaning the least disrespect or offence to the lecturer, who, with all honesty of purpose, might have been deceived. He had had experiences of his own, not photographic in their nature, of a most wonderful kind, and he believed from that that telepathy was a real, established fact.

A long discussion followed the chairman's remarks. Three or four gentlemen spoke of having had appearances on photographic plates which bore out the lecturer's statements, but the general feeling of the meeting appeared to be hostile, while some did not hesitate to state their belief that the pictures shown were faked. The meeting closed at a late hour, with the usual compliments to the lecturer and the chairman.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION, EDINBURGH BRANCH.

APRIL 15.—Present: Messrs. Salmon, Bibbs, Warren, Banks, Drummond, Young, and Moffat, hon. secretary. Mr. Bibbs occupied the chair. Apologies of absence were received from Messrs. Crook, Balmain, and Crawford. The following subjects were discussed: (1.) Which is the better business method for photographers? Credit at time of sitting or credit. Most of the members present advocated the former method, but it was pointed out that it depended very much upon who the customer was; for well-known people it was more profitable to get them as credit customers than make them pay cash down. (2.) Should photographers allow their copyright photographs to be reproduced in the local papers, free of charge? It was pointed out by the secretary that at present it was the custom in Edinburgh for photographers to allow the two Edinburgh evening papers to produce their copyright photographs free of charge. The question

for which was the advertisement they got by having their names acknowledged as from their photographs. The meeting, after considerable discussion, were strongly in favour of members of the Association combining to charge a modified fee for these copyright photographs. It was ultimately agreed to bring this matter up again at the next meeting.

An interesting discussion also took place on the free portrait trade and residues.

RICHMOND CAMERA CLUB.

APRIL 28.—Dr. Rodman showed a stereoscopic radiograph of a shell which the details of its internal convolutions were very well displayed. This is probably the first attempt at producing stereoscopic effects by means of the X-rays. Dr. Rodman explained that to produce the effect the shell was first placed upon a photographic plate two inches from one side of the vertical line through the centre of the illuminating tube and at a distance of ten inches below it. After exposure it was placed upon a second plate at a distance of two inches from the other side of the vertical line and again exposed, the exposure given in each case being about twenty-five seconds.

The business on the agenda for the evening was the exhibition and judging of members' competitive prints. Mr. Cembranc acted as judge, and awarded the club medal to Mr. Huddy for three fine hole-plate prints, and he adjudged the second place equally to pictures shown by Mr. Gibson and Mr. Sargent.

HULL PHOTOGRAPHIC SOCIETY.

APRIL 30.—There was a splendid attendance to visit Barrow and Harrow Haven, the latter forming material for more plates than one could spare. The lanes en route from New Holland were alive with amateurs and cameras, who eventually got into smaller parties, and it is hoped much good work will result therefrom. As to the social part of the afternoon, this was everything that could be desired, and the members who did not trouble to carry a camera thoroughly enjoyed advising and assisting those who had, in some cases, two. The early part of the day was somewhat unpromising, but by train time it cleared off, and was for the rest of the afternoon charming, and accompanied with a high wind, which dropped for the evening. The bulk of the exposures being made after tea. The half-hour so at the tables is always a sign of animation, and that at Barrow was no exception to the rule. After satisfying the inner man a move was made, and the most serious work was done, and by the time the light failed all traps were packed up, and a charming walk of three miles along the Lincolnshire coast of the Humber brought a most successful outing to a close, proving that the special efforts of the new president and the secretary had borne that fruit they richly deserved. Prints from the negatives are to be submitted at the monthly meeting on Thursday, May 5, for criticism and each other's edification, which will be kept up through the summer, and it is thought, to the pleasure and instruction of younger members, who are to receive every possible attention and encouragement.

The next outing is to Westella, May 14, by 'bus, train, or "bike." and should call for even a larger attendance and greater enthusiasm than ever.

NORTHERN Photographic Exhibition.—The successful termination of this exhibition was celebrated on Friday evening at the Hotel St. George, Liverpool, by a dinner given to the hon. secretary, Mr. C. E. Inston, to whose hard work and perseverance the great artistic, as well as financial, success of the exhibition was due. After dinner the chair was taken by Dr. Llewellyn Morgan, who read a letter from Councillor John Lea, Chairman of the Arts and Exhibition Subcommittee, regretting his inability to be present. After giving the royal toasts, the Chairman proposed "Our Guest," and presented Mr. Inston with a handsome silver tea and coffee service, as some slight recognition of his work as hon. secretary. Mr. Inston, in returning thanks, said he considered that all the credit was not due to himself, a great deal being due to other members of the committee. The remaining toast, "Our Society," was proposed by Dr. John W. Ellis, and responded to by Mr. Fred Schierwater, President of the A.P.A. Several musical items were rendered by Messrs. Thomas Steel, J. Ryalls, George Theakstone, and Harry Gandy, Mr. Edward Hugh acting as accompanist.

News and Notes.

THE Thornton Pickard 1904 Catalogue is to hand. It is very complete and well illustrated, and contains many new specialities in shutters and cameras. A copy containing full particulars and prices will be sent gratis and post free on application to the Thornton Pickard Manufacturing Company, Ltd., Altrincham.

THE Royal Photographic Society of Great Britain.—An ordinary meeting will be held at 66, Russell Square, on Tuesday, May 10, 1904, at 8 p.m. "Progress in Enlarging" (with examples and specimens) will be given by Mr. Howard Farmer. "Irradiation as a phenomenon in negative making and printing and its application to colour photography" (with specimens), by Mr. Howard Farmer and Mr. Guy Symmons.

HEPORTH Manufacturing Company, Limited.—This Company has been registered with a capital of £4,000 in £1 shares. Object, to acquire the business of cinematographers, now or lately carried on by C. M. Hepworth and H. V. Lawley at Walton-on-Thames and 17, Cecil Court, Charing Cross Road, W.C., as Hepworth and Co., and to carry on the same. No initial public issue. The first directors are C. M. Hepworth, S. Barker, and E. J. Humphrey. Registered office, 17, Cecil Court, Charing Cross Road, W.C.

MESSRS. HOUGHTON, Limited, have kindly sent us a print from the flash-light negative taken on the occasion of the inaugural dinner of the Company, held at the Trocadero Restaurant on April 9. We shall value the print as a souvenir of an interesting celebration. Technically it reflects great credit on its producers, Messrs. J. Jacks and Co., of 22-24, Glasshouse Street, London, W., the exposure being full, whilst the likeness of each person present at the dinner is well rendered.

THE Cripplegate Photographic Society held its annual social evening on Saturday, April 23. A most enjoyable programme was rendered, mostly by members, and the society is to be congratulated on having such excellent musical talent among its members. Some hundred or so of members and friends gathered together in the pretty and comfortable hall of Cripplegate Institute, and altogether a most enjoyable evening was spent. The medals awarded at the recent exhibition were presented during the evening.

THE Photographic Dealer's Annual for 1904 is to hand. In addition to containing a mass of reliable information likely to be of great help to the dealer, the advertisements themselves of which there is a goodly collection, will also prove useful for reference. Among the articles we notice "The Testing of Photographic Lenses," by S. D. Chalmers, M.A.; "Recent Changes in Modern Chemistry," by Edwin Banks; "The Care of Photographic Stock," by A. Lockett; and "An Outline of Tricolour Photography," by A. C. Jolley.

ART Union of London.—The general meeting of the members of the Art Union of London was held last week at the rooms of the Society of Arts, John Street, Adelphi, when the annual report of the council was presented and the prizes of works of art distributed. As the subject for the coming year's presentation etching the council have chosen the picture by Mr. Alfred East, A.R.A., entitled "The Miller's Meadow," which was exhibited in the New Gallery Exhibition of last year. The picture, which was generally recognised as one of Mr. East's finest compositions, was selected by the Royal Commission as a representative British painting for the coming exhibition at St. Louis. Unfortunately, the necessity for its being in the engraver's hands until the present moment prevented its being sent to America.

THE Duke of Argyll, in giving the toast of "The Chairman, and Prosperity to the Royal Society of Painters in Water Colours," at the centenary dinner of the society, said the society had been established for a long time, and it was the father if not the patriarchate of the art of water-colour painting. After remarking that they all deplored the fate of the distinguished Russian artist Verestchagin, he recommended artists to visit Canada, where they would find every characteristic they wished for. Another reason which should induce some of them to go to Canada was that modern art in that country was more appreciated than it was in Europe. We were apt here to slavishly adore a picture simply because it was by an old master. For that reason alone it would be well if some of them were to visit Canada and the United States.

FREE Newspapers.—Not content with the monster newspapers which they receive in exchange for a cent Americans are beginning to discuss the possibility of being supplied with free newspapers, without money and without price. The idea is that the advertiser should pay the entire cost of production and provide the newspaper proprietor's profits. This is declared feasible on the ground that a newspaper given away for the asking would constitute the richest of all advertising bonanzas. Will English advertisers take this view, however, and hold to it? We can see in the future the "Daily Thunderer" advertising for subscribers to read that paper; one guinea a year offered to every one who will undertake to wade through the contents of its mammoth sheet, the inducement being that its advertisements are drawn up by the leading literary writers of the day.

THE Blairgowrie and District Photographic Association has arranged to hold an international exhibition—the fourth promoted by the Association—just after the Scottish Salon of 1905—pictures shown at the Salon will be forwarded to Blairgowrie, free of charge. The open classes are: Champion, landscape, seascape, and river scenery; portraiture and genre, including animals; any subject not included in above; lantern slides; and illustrated lecturette. The associates of the Scottish Photographic Federation have one class—any subject—reserved for them, and the societies forming the Federations are offered a special prize for the best collective exhibit. A special silver plaque will be awarded to the best picture in the exhibition. Messrs. J. Craig Annan, Glasgow; Wm. Crookes, Edinburgh; and Arch. Cochrane, Glasgow, will judge the exhibition; and Mr. Alex. Keighley, Keighley, will judge the lecturettes.

ALPINE Photographs.—The hall of the Alpine Club, 23, Savile Row, is well filled with photographs of mountain crest and peak, seas of ice, fairy-like snow pictures, and delightful glimpses of the world above the clouds, which make the exhibition in its way unique. That the everlasting hills change but little is true, but the new methods of expression and original points of view which many of the exhibitors exemplify lend the necessary charm of variety to the Alpine Club's long succession of similar displays. Of the numerous clever works perhaps the most notable is No. 58, "Lakes of the Val Pivoia from the Col Tanicola," by Mr. E. J. Garwood, a fine piece of technique and a striking subject. Much the same may be said for Mr. Henry Speyer's "Signalkappe." A mountain top soars above a sea of clouds which look like waves of mist beating against its flank. Other notable exhibits are those contributed by Mr. John Gunston ("Mer de Glace"), Mr. J. W. Wyatt ("The Rathhorn"), Mr. J. J. Withers ("Montanvert"), and Mr. Sydney Spencer, whose graceful and decorative effects of melted snow, dark crags, sunshine, and fir trees at Pontresina merit approval. Dr. W. Hunter Markman shows a number of Himalayan scenes, in some instances of peaks which he was the first to scale in 1903.

At the Mansion House Police Court on May 2, William Freise Greene, of 8, Cliff Villas, Dovercourt, appeared upon a summons before Mr. Alderman Burnett charged with obtaining £72 from Mr. Favina, secretary of the Commercial Intelligence Bureau, Eastcheap, and £60 from Mr. Aitken, East India merchant, of 29, Mincing Lane, without disclosing the fact that he was an undischarged bankrupt. Mr. Cohen prosecuted and Mr. Langford defended. The accused, who had been a photographer in Regent Street, failed in 1891, with liabilities amounting to £2,152, and assets nil. He had not since received his discharge. In August last a petition was again presented against him, when his liabilities were set down at £227. The defendant, who was described as an inventor and patentee, appeared to have shortly before his second bankruptcy obtained loans for the amounts in question from Mr. Favina and Mr. Aitken without disclosing the fact that he was an undischarged bankrupt. In cross-examination Mr. Favina said the defendant was the owner of several inventions but he did not know whether they were valuable or not. Mr. Langford: Is he the original inventor of the cinematograph?—The Witness: I cannot say. Do you doubt it?—I do rather. Then he is the inventor of printing by electricity and of animated pictures?—He has taken out patents in connection with them. Did he not register the Animated Picture Syndicate, Limited, and were you not anxious to put money into it?—No, I was not. What I wanted was to act as an agent for the introduction of purchasers of the patent. And proposals were made by which you were to have a substantial interest in the invention?—I was to have an interest. Mr. Aitken said the defendant told him he had sold a motor engine patent to a Cardiff firm for £15,000,

and required £50 of the £60 as a temporary loan. The defendant who reserved his defence and pleaded not guilty, was committed for trial, being allowed bail in one surety of £100.

SIR ERNEST WATERLOW, R.A., in his speech at the centenary dinner of the Royal Society of Painters in Water Colours, said that the members and associates were celebrating this year the 100th anniversary of the founding of the society. It was an event which no body of artists in this country, except the Royal Academy, had hitherto celebrated. Its history was recorded down to the year 1804 in the two large tomes of Mr. Roget. From that time, however, they had been without a chronicle, and he mentioned this in the hope that there might be a historian among them to bring the history up to date. Their historian reminded them that the Annual Register for 1804 recorded the death of Nelson, but failed to record the birth of the society. It was truly lamentable that such a sturdy infant, as they might take it the society was, should be unregistered and therefore be unable to produce a birth certificate. The fact, however, remained, and they could only impress it upon those present that the Annual Register was incomplete. The coming together of water-colour painters for the first time on November 30, 1804, laid the foundation not only of this society, but of the success of an art which had since extended its peaceful influence to all civilised countries. From that time forward the art of water-colour painting took strong hold upon the public favour, and the election of a new member of the society ensured the attention of the writers of the day to his work. A propos of this, they found no less eminent a personage than Thackeray in his critical essays referring to one of their members: "A new painter somewhat in the style of Harding is Mr. Callow. This was written in 1840, and Mr. Callow was still an honoured and most active member of the society, painting as well as ever at the ripe age of 92. He trusted it would be the constant aim of the society so to improve upon the methods and practice of their predecessors that it might be said of them in the future, as they could say of those who had gone before, that they also had done something worth of remembrance for the essentially British art of water-colour painting."

PROPOSED Optical Convention.—At the instance of the Optical Society a meeting was held on April 26, at the Society of Arts, to consider the advisability of organising an Optical Convention in this country. Dr. R. T. Glazebrook, who occupied the chair, said that the need for further co-operation between the various members of the optical industry was widely recognised—more fully, perhaps, in Germany and in France than in this country. It was this fact that had led some members of the Optical Society to issue a letter inviting an expression of opinion as to whether a convention should be held for the discussion of matters of interest to the optical trade. The reply had been favourable, and this meeting was the result. This convention, it was thought, should be independent of existing organisations, and he himself hoped that along with it there would be an exhibition of optical instruments to show what the English optical trade could do. The resolution in favour of such a convention, to be held in London, was proposed by Mr. C. Hyatt-Woolf, who said that it was remarkable that up to the present so important an industry as the optical had not seen the necessity of combined meeting and inquiry. He thought that the convention should not be confined to the education of opticians and the enlargement of their sphere, but also to the education of the public as to the progress of the optical craft. Mr. Cornbeck, in seconding the motion, said that he found that among scientific men there was a generally accepted idea that the British optical industry was dying, if not dead; and, holding this opinion, they could not be expected to take a keen interest in the optical craft. But there were still some optical industries in this country which surpassed those of any other country, while in others we had our own. The convention would aid in bringing about that close touch which was so desirable between scientific and practical men. The motion was supported by a number of speakers, including Mr. W. M. Christie, the Astronomer Royal, who said that lately he had been pleased to notice a distinct awakening in the photographic branch of the British optical industry, and it was carried unanimously. It was further agreed that an organising committee be appointed, and suggestions were invited and received for names of gentlemen who should be asked to serve.

When ordering half-tone blocks, photographers will usually get better results if the block-maker is given a certain amount of

ration. The following excerpts from notes on the subject in the "American Printer" should prove useful:—Obtain the best possible photographs or drawings of subject to be reproduced. State the style of finish preferred—straight edge, oval, circle, outlined, or cut-top, vignetté, or with fancy drawn border. State the number of inches wide you want each plate, or the number of inches high. Give clear instructions as to parts not wanted, the fixing up of incorrect portions, or making additions. If a price has not been quoted, state about how much the job will stand for extra work of artists, photographers, or finishers. State any special orders concerning printing; mounting plates can be blocked flush on either side or on both sides. Say how much time can be allowed. Carefully protect plates against rough handling in transit. Now some don'ts: Don't rely on the backs of unmounted photographs. Don't send untinted or unfixed photographic prints; better send the photographer's negative. Don't expect half-tones at regular rates from coloured plates. Don't give dimensions, both length and breadth, of plates required. Don't send smaller photos than plates are to be, if it can be avoided. If the plate is to be used in a newspaper and stereoscopic with type formes, then order, according to the subject, the half-tone to be made through a 55, 65, or 75-line screen and on zinc, for on this metal engravers are able to get greater depth on the plates, a valuable help in obtaining results from half-tones when compared from stereotyped plates. If the newspaper publisher prints plates from half-tones, still order them made through a coarse screen either the 85, 100, or 120, according to the subject, and to be made on zinc on account of the cost price, and the printing quality. Depth most helpful when cheap ink and coarse paper are used. On the other hand, the half-tones required are for the higher grades of printing, such as trade papers, high-class magazines, catalogues, booklets, etc., the printer will order his half-tones made either through 133 screen, 150, 175, or 200, according to preference, quality of paper to be used, or the detail required in the plate. A portrait will look better than any other subject made through a coarse screen. In reproducing machinery, scenery, and mechanical articles in catalogues, the finer the screen the more true to the copy the result will be when printed.

ROYAL INSTITUTION.—The annual meeting of the members of the Royal Institution was held on May 2, Sir James Crichton-Browne, D., treasurer and vice-president, in the chair. The annual report of the Committee of Visitors for the year 1903, testifying to the continued prosperity and efficient management of the Institution, was read and adopted, and the report on the Davy Faraday Research Laboratory of the Royal Institution, which accompanied it, was also read. Seventy new members were elected in 1903. Sixty-two lectures and twenty evening discourses were delivered in 1903. The books and pamphlets presented in 1903 amounted to about 229 volumes, including with 694 volumes, including periodicals bound, purchased by the managers, a total of 923 volumes added to the library in the year. Thanks were voted to the president, treasurer, and the honorary secretary, to the committees of managers and visitors, and to the donors for their valuable services to the Institution during the past year. The following gentlemen were unanimously elected as officers for the ensuing year:—President, the Duke of Northumberland; treasurer, Sir James Crichton-Browne; secretary, Sir William Bouverie; managers, Dr. Henry E. Armstrong; Sir William Abney, Sir Sheldford Bidwell, Sir Alexander Binnie, Mr. J. H. Balfour Browne, K.C., the Hon. Sir Henry Burton Buckley, Sir Thomas A. Blane, la Rue, Bart., Dr. J. A. Fleming, Sir Victor Horsley; Lord Kelvin, Dr. Ludwig Mond, Sir Owen Roberts, Sir Thomas Henry Anderson, Sir Felix Semon, and Mr. W. H. Spottiswoode; visitors, Mr. J. Mitchell Bruce, Mr. J. B. Brodin-Morison, Dr. F. Clowes, Mackenzie Davidson, Mr. W. B. Gibbs, Mr. Francis Fox, Mr. C. Melchers, Mr. R. Mond, Mr. J. Callander Ross, the Hon. Walter H. Russell, Mr. Maures Horner, Mr. A. A. Campbell Swinton, Mr. J. Veze, Dr. G. Johnstone Stoney, and Mr. G. P. Willoughby. A demonstration of "Photolinol" was given before scientific and press representatives at the works and studios of Photolinol, Limited, 10, Holland Park Avenue, London, W., on Friday last. An extensive selection of work showing the capabilities of the process was on view, and many of the examples might be classed as works of art. Some charming coloured effects were also shown, and an ingenious studio arrangement, the idea of Mr. Otto Fulton, one of the inventors of the

process, proved what could be done with Photolinol as a studio accessory. Some of the chief advantages claimed for this photographic linen are extreme ease of manipulation; having a bromide emulsion it may be enlarged on or printed by contact in the same manner as bromide paper. The material is practically indestructible, waterproof, and impervious to the action of the sun, and has a high transparency. It can be rolled, pasted, or stretched without the slightest injury to the photograph. The picture thoroughly permeates the fabric, and has every appearance of being woven into the material. When coloured it presents the appearance of a solid oil painting, by reflected light, and by transmitted light, it gives a perfect coloured transparency. Without close inspection, or touching the material, it would be possible to mistake it for a stained glass window of most costly design and execution. Pictures up to 15 feet height and any reasonable length can be produced. It also serves as a basis upon which the artist may produce a picture in oil or water colour, the foundation of which may be a photograph taken by himself or by others, the material being exactly similar to the canvas usually used for oil paintings. It can also be used as a foundation for art needlework. For the production of photographic enlargements where at present bromide paper is used, also for backgrounds for photographic studios. For pictorial window blinds, illuminated posters for the theatrical profession, show cards, and fashion plates, etc. Messrs. J. Griffin and Son, Limited, of Sardinia Street, W.C., have been granted the sole agency for Great Britain and the Colonies for the plain materials.

THE St. Louis Exhibition, which was opened on Saturday last, is at last an accomplished fact, and the result of five years' constant labour of over 30,000 workmen is open to the world's inspection, while newspaper readers are probably already aware that nearly 300,000 people were present when President Roosevelt set the great cascades going, unfurled all the flags, and started the machinery by pressing a button in far-away Washington. Of the British exhibits, which will perhaps be the first item of interest to the British visitor, our country will be found to be very fairly represented in many departments, as may be judged from the fact that the official catalogue is a bulky volume nearly three inches thick. According to the "Times" correspondent, it is perhaps strongest in the sections of art, the liberal arts especially, photography, chemistry, mining, and metallurgy, and social economy, and it is noteworthy that in these cases the Royal Commission appointed a year ago, with the Prince of Wales as president and Lord Peel as chairman, has taken upon itself the task of superintending the organisation of a collective exhibit. Applications made to individuals before the Royal Commission came on the scene with a supply of funds to back combined and systematic effort proved of little avail. In regard to manufacturers, in many cases no response at all was made to the letters. In others, when replies were sent, the writers seemed disposed to detect an insult to their intelligence in the suggestion that they should exhibit goods in a country protected by hostile tariffs; or they intimated that they were so full of orders that to exhibit would do them no good; or they displayed that melancholy self-sufficiency which thinks it has nothing to learn from others, and stated that they did not propose to educate the foreigner in their own superior methods. The policy of arranging for, and often paying the expenses of, collective exhibits—a new one for Great Britain—was therefore found to be inevitable, if, as was plainly desirable, this country was to take an adequate part in the Exhibition. The Governments of other countries have long adopted this method of advertising their productions to the world, and have not hesitated to spend liberally in order to carry out their purpose. For example, on the present occasion Germany, although her trade interests with the United States are less than those of this country, is spending more money on her collective exhibits, and in addition she has allocated a large sum to enable some of her artisans and mechanics to pass a fortnight in inspecting the exhibition and in learning what her trade rivals are doing. It can scarcely be supposed that she spends her money just for the fun of the thing, without some expectations of gaining solid advantages from the expenditure, and perhaps some day the people of this country will come to believe that tangible benefits are to be obtained from participation in international exhibitions. But at present it must be admitted that such exhibitions are not popular among us.

Correspondence.

THE KODAK COMPETITION.

To the Editors

Gentlemen,—We have pleasure in informing you that the following well-known gentlemen have consented to act as judges in the Kodak £1,000 competition, for which entries will be received until June 30:

Sir William de W. Abney, K.C.B., R.E., D.C.L., F.R.S.

J. Craig Annan, Esq.

Frank M. Sutcliffe, Esq.

Will you have the goodness to convey this intimation to your numerous readers in the next issue of the BRITISH JOURNAL OF PHOTOGRAPHY?—Yours faithfully,

KODAK, LIMITED.

41-43, Clerkenwell Road, E.C.,

April 28, 1904.

PROTECTING PROOFS.

To the Editors.

Gentlemen,—With very great interest I read your "Ex Cathedra" paragraph on "Frauds on Photographers." As I was a victim of these malpractices for many years, I from time to time tried many methods by which I may impress upon sitters that the rough proofs I send out are my sole property and must in no case be retained by them. But no method has been a complete success until I adopted the one I now employ, an illustration of which I enclose that you may see for yourself, and if you think the idea as good as I find it you may pass it on for the benefit of your readers.—I am, yours faithfully,

HENRY J. COMLEY.

"The County Studio," 10, Russell Street, Stroud,
May 2, 1904.

[Our correspondent encloses a print perforated in three places with the word "Proof."—Eds. B.J.P.]

A DISCLAIMER.

To the Editors.

Gentlemen,—A warning notice directed against me and published in your magazine was brought to my notice some time ago. I have been doing a mail order business up to about 50,000 dols. per annum, and like all American dealers, I was obliged to exchange used cameras and lenses. Quarterly I issued bargain lists, requesting my customers to state first, second, or third choice, reserving the privilege to substitute other goods, however, with the assurance to the customer that money would be refunded if any of the goods proved unsatisfactory.

Mr. Walter Bruce, the writer of the article, sent 8 dols. for a lens, which upon receipt of his order was sold. We sent another, which he returned. A refund check was mailed, but by an oversight was enclosed in another customer's letter; however, another refund check was mailed to him on November 30, and was received by him on December 1. He did not cash this check before December 26.

To again return to the accusations published by you, I desire to state that I have manufactured photographic lenses for over six years. Messrs. John J. Griffin and Sons, Limited, had purchased goods from me very extensively, as per order enclosed. I enclose you German catalogue, showing you plainly that the goods were manufactured by me. Mr. Bruce cannot name the five friends in his city which he claims have been swindled.

If "Amplisopes" would be inferior, they would not have been bought by all. "La Revue Scientifique," Paris, "Scientific American," New York, and all photographic magazines, would have never praised the goods, and if you will look over the records, you will find that I have been the inventor and first manufacturer of supplementary lenses. Focussing finders are in use in England, and Mr. George Eastman at a time seriously considered the same.

Your article has been the means of great loss to me. I have been

obliged to turn over my business to my clerks at a sacrifice. You have without investigation ruined the tedious work of many years and your action is so extremely unfair, that it is not in line with your long experience and your standing as a publication, and it is no encouragement for the younger element to push ahead.

I have now an opportunity to connect myself with the above having assigned to them an exceedingly valuable patent, as copy enclosed, but before such is possible you must make good the great wrong you have done me.—Yours truly, N. NEHRING.
The Scientific Lens Co.

Manufacturers of High-grade Lenses,

704-714, East 166th Street, New York,

April 19, 1904.

[Accompanying Mr. Nehring's letter was a catalogue (in German) his Amplisopes, and a copy of "Western Camera Notes" (Mimnapolis) in which that periodical states that its business relations with Mr. Nehring have always been satisfactory. Three original letters from American photographers were also enclosed, and these testified that his goods were as represented to the writers. Finally, Mr. Nehring sends us the original order from a London house for a large number of his Amplisopes. We are extremely sorry if the publication of Mr. Bruce's letter exerted any adverse effect on Mr. Nehring's business, and trust that the foregoing disclaimer and these appended evidences of Mr. Nehring's bona-fides will exonerate him from the accusations made by our American correspondent.—Eds. B.J.P.]

PSYCHIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—In regard to spirit photography, Mr. Boursnell, photographer having a shop and studio in Uxbridge Road, is the only taker of spirit photographs in this country. Since 1895 he has been taking them regularly by the side of clients who applied to him. He is naturally clairvoyant, which means that he can see spirits both in daylight and darkness, and like all clairvoyants, is a spiritualist, for birds of a feather flock together. He soon found that he had to contend against sceptics, and put himself in a state of defence, entrenching himself the best way he could in the stronghold of truth. To that end he had cards printed on which were code of rules constituting the conditions on which he would meet the demand for a spirit photograph. One of the rules was that the applicant must bring his own plates, three or four in number, and that they must be already marked with the name or initials of the owner. Another of the printed rules was that the applicant must go into the dark room himself (if a photographer, whether amateur or professional) to put plates in slides, and again to develop the plate after due exposure. Mr. B.'s rôle in the performance being confined to the small part of taking at the camera the photograph of the client on the platform. And it was here where his service as clairvoyant was indispensable, for he would see a denizen of the spheres, a man, a woman, or child, posing calmly by the sitter's side. After usual exposure on the sitter and covering the lens the camera has to remain undisturbed for a minute or so to finish taking the spirit. The spirit being less dense, takes a longer time to photograph, and mysteriously enough, the cap is no hindrance to the spirit light-rays impinging on and focussing through the lens. There is thus another light besides the everyday commodity we are familiar with. In less than fifteen minutes all three plates brought and produced by a client will have been exposed and developed, and a spirit picture revealed on one of them, sometimes on two. If the applicant is not a photographer he must enter the dark room with the operating medium before and after exposure.

During nine years Mr. Boursnell has catered for hundreds of customers of every rank, including army officers, university professors, clerics, Jesuits, photographers, medical gents, members of Parliament, from all parts, including Paris.

The Boursnell photographs are a series by themselves, and exceed over all the previous ones mentioned in Mr. Henderson's ancient history in his recent letter anent the seventies. Mr. Boursnell is now seventy, and feeble, and I do not know of any other to be relied on for a spirit photograph.

J. E. STERLING.

91, Latchmere Road, S.W.

P.S.—I had the honour some five years ago of submitting to Mr.

Anderson at the rooms of the Land Photographic Society a number of specimens of Mr. Boursnell's psychic photographs. He was much pleased, and apparently satisfied. He promised me that he would suddenly on Boursnell with half-a-dozen marked plates in his bag, and demand a spirit photograph on one or more of them within the usual limit of time—three or four minutes for each. Had he done so he could have produced some light on the subject in recent letter, which vouchsafes no information, only a cry for help from other quarters. In 1895 I showed Mr. J. Traill Taylor, then editor, some of Mr. B.'s photographs of spirits, and he, I could see they were not "fakes," but genuine, and told me with every expression of satisfaction. Last October Mr. Boursnell was the recipient of a beautiful illuminated address from a large company of gentlemen of high social standing, to recognise his gift as a spirit photographer, and his immaculate probity and dealing. It can be seen framed at his house.

A RECORD in Block Making.—A few nights ago several artists were invited by the "Daily Chronicle" to Portsmouth to draw the sad scenes of the burial of the Submarine A1 victims. The firm of Carl Schuchel, Ltd., received their finished sketches at 11.15 p.m. In an hour and twenty minutes the chief in person hurried over to the "Daily Chronicle" office with plates equal to about three-quarters of full-page size; all perfectly finished; thoroughly deeply etched, clear and clean at all points. Thus Portsmouth and other readers of the "Daily Chronicle" have fine illustrations of the historic scenes on their breakfast table. The record which secured the warm congratulations of the editor of the "Daily Chronicle." What a far cry to the days of forty years ago, when, in publishing the news of Lord Palmerston's death, a dingy illustrated journal announced that in a few weeks it hoped to present a portrait of his lordship.

ON Lead Poisoning and Water Supplies.—The second volume on the above subject has recently been issued by the medical officer of the Local Government Board. The former volume contained information concerning Dr. Houston's study of waters derived from moorland filtering grounds in Lancashire and Yorkshire; the present volume gives details of an extensive series of laboratory experiments bearing on the general subject and conducted by Dr. Houston. They have been published in order to facilitate the interpretation of the results obtained when studying the solvent or erosive power of a water on lead pipes, with the view of counteracting these dangerous qualities. Particular attention is directed to observations on "standards" (p. 10) in this volume, where methods of measuring the solvent and erosive powers of a water upon lead are given enabling an opinion to be formed as to the degree of risk arising from the contact of such water with lead surfaces. The report is illustrated with drawings of the apparatus employed in the investigations, and photographs have been reproduced to show the actual amount of deposit remaining in tubes in which erosion of lead by water has been allowed to take place. From the nature of this report it will be understood that the substance of it consists of the tabulated results, together with brief descriptions of the experimental methods adopted. The main conclusions arrived at were stated in the previous volume, but a general summary of all conclusions is also given in Section IV. of this volume. Reference to this summary will be found useful to those who are concerned with the consideration of dangers of lead poisoning arising from water supplies. The summary starts with an explanation of the meaning of the term "erosion," and proceeds to state that bright lead is rapidly eroded by rain and by snow water, as well as by distilled water; then follow the names of substances which do not influence the erosive power of water when introduced into it, as well as of substances which delay and inhibit the action. Moorland waters are next considered in regard to their erosive property, and the conditions which increase, diminish, or prevent their erosion are stated. Then follow cases which do not fall under the above classification, together with remedial measures which may be adopted to avoid danger. A similar classification and consideration of waters as regards plumbo-solvency then shortly entered into, and, finally, the conclusions arrived at in chemical and bacteriological experiments as to the cause of acidity in moorland water are given. The summary terminates with a selection of conclusions which have already appeared in the former volume.

Answers to Correspondents.

- * * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.*
- * * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- * * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.*
- * * *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPHS REGISTERED :—

- G. H. Henshall, 8, Violet Road, Linacre, Liverpool. *Photograph of Raby Mere, Bromborough, Cheshire.*
- J. Shivas, 88, Queen Street, Peterhead. *Photograph of View of Peterhead.*
- R. P. Gregson, 37, Church Road, Lytham. *Photograph of the English Association Football Team v. Wales, 1904. Photograph of the English Association Football Team v. Ireland, 1904. Photograph of the English Association Football Team v. Scotland, 1904.*
- H. Wiggins, South Parade, South Shore, Blackpool. *Photograph of Stormy Sea at Blackpool.*
- H. Waters, 117, Crown Street, Ipswich. *Photograph of H. Wilmetts, Neger Comedian on Pedestal.*

J. H. HELSLY.—We must trouble you to put your query in a more definite form, as we do not understand what you mean by a formula for "sensitising, developing, and fixing solar prints."

ADDRESS WANTED.—"PICTORIAL" says: "I should be obliged to you if you can give me the address of S. Hildesheimer and Co., London and Manchester, postcard firm." In reply: Finsbury, London, E.C., will be sufficient address.

R. W. BROWN asks: "I should be obliged if you could inform me where I could purchase a camera for taking photo post-cards to be finished in a few minutes. I am thinking of doing the same here during the season, but am at a loss to know how they are done." In reply: We are not aware that there is such a camera on the market.

COPYRIGHT IN INDIA.—"H. C. S." (Bombay) asks: "Could you inform me whether there is a Copyright Act in India, and if so, where should I apply to have photographs registered?" In reply: We must confess that we are unable to answer the question as to copyright in India. As our correspondent is resident in India, we should advise him to inquire there.

TRIPOD asks: "Will you kindly supply me with the names of two or three of the best books on posing and lighting for artistic portraiture in studio? I do not want little handbooks; good standard books will be of most use." In reply: We advise you to get "The Studio, and what to do in it," by H. P. Robinson; "The Lighting in Photographic Studios," by P. C. Duchochois; "Artistic Lighting," by James Inglis; "The Pose in Portraiture," Photo Miniature No. 2.

RESIDUES.—H. HOLDEN says: "I should be glad to know (1) the best way to collect the precious metal from used toning and fixing baths. (2) Could both baths be treated in one operation, that is, together? (3) And should I not obtain gold and silver residues, as there is sure to be a little gold left in the old toning bath." In reply: (1) The gold may be precipitated from the toning baths by an acidified solution of protosulphate of iron; and from the fixing baths by a solution of sulphide of potassium. (2) The baths should be kept separate. (3) Yes.

VALUE OF LENS.—Q. W. L. asks: "Would you kindly inform me what is the value of a portrait lens by C. C. Harrison, New York, No. 5,217? It was made in 1858, and will take a full-length portrait 34, by 25, or larger, the whole of the figure being sharp." In reply: We are not valuers of old apparatus, so can give no actual opinion. We should imagine, however, the lens has comparatively little commercial value at the

present time, as when portraits of the size mentioned are required they are produced by enlargement.

OPINION WANTED.—C. DE B. (Jersey) says: "I enclose you four rough prints, two before retouching and two after. May I ask you if you would kindly give me your opinion of the work, and how many ought one to retouch of that size in a day? I am rather slow; I can only just manage to do five or six. Could I apply for a berth and say that I can retouch?" In reply: We cannot say much for the work; we should advise our correspondent to improve it before applying for a situation as a retoucher. He might do well, perhaps, to read the article on another page.

SPOTTY PRINTS.—T. R. HAMMOND writes: "For some time past I have been troubled with spotty prints, and have failed to trace the cause; I should therefore be obliged by your advice. The spots appeared the morning after mounting. I have tried covering up during drying, but still they appear. All baths are made up fresh. I have worked under the same conditions for three years without trouble until now." In reply: Judging from the appearance of the spots, we should say that they are caused by minute particles of injurious matter coming in contact with the prints while they were wet. Is the water free from iron?

CHARGE FOR USE OF DARK ROOM.—G. W. LANE writes: "I am a photographic dealer, and have just had a very convenient dark room made, which I intend 'letting' for the use of amateurs. It is fitted with running water, sink, and all the usual accessories. I should be glad if you could give me a scale of charges usually made." In reply: There is no regular scale of charges; every one fixes his own according to his ideas. Some dealers make no charge to their customers for the use of a dark room for changing plates. Others make a charge according to the time the room is occupied, and again others according to the purpose required, i.e., plate-changing or developing, etc.

COLLOTYPE.—"RUSTICUS" writes: "I have read your very interesting article in to-day's B. J. on colloid printing. You mention in the latter part that there one or two simpler modifications of colloid, without a glass plate, particularly useful for post-card work. When only a few copies (comparatively) are required off each negative, can you give me any information about these: Is 'Sinop' such a one? or should I find it in Fithian's 'Practical Colloid'?" In reply: "Sinop" is well suited for the production of picture post-cards, but with it a glass plate is employed. The Photo-auto-copist is also good; with it plates are not employed. The address of the Auto-copist Company is 64, Queen Victoria Street, E.C. Fithian's is a good general work on colloid.

PHOTOGRAPHING IN AMERICA.—E. PHELP asks: "Will you be so kind as to give me an answer to the following question:—Is there any statutory prohibition to taking photographs of public or state buildings in the United States of America? With a desire to photograph public or state buildings, would you advise me to carry a passport? My reason for asking this question is that I am an amateur photographer, planning a holiday in U.S.A. for the next two months, and do not wish to carry my camera all the time if there is any great restriction on same." In reply: So far as we are aware there are no restrictions as regards photographing public buildings in the States. But you can make sure on the point by applying to the American Consulate in London. No passport is required in America.

SUPPLEMENTARY LENSES.—E. Y. E. N. asks: "(1) What focus spectacle lens should be added to a 5in. Busch anastigmat (f.6) to convert it into a 3½in. focus lens? (2) The front is the most convenient; is this the best position? (3) Would it be possible to get two such spectacle lenses to fit exactly a pair of stereo lenses? (4) Is this a right calculation for query 1? Assuming a 12in. spectacle lens is used, then $\frac{12 \times 5}{12 + 5} = \frac{60}{17} = 3.53$ (nearly)." In

reply: (1) To find the focal length of supplementary lens necessary to reduce or increase the focal length of a given lens, multiply the focal length to be altered by the final focal length desired, and divide the product by the original focal length less the final focal length $\frac{f \times F}{f - F} = \frac{5 \times 3\frac{1}{2}}{5 - 3\frac{1}{2}} = 11\frac{1}{2}$, therefore a

positive lens of 11½in. focus will give you the focal length required. (2) It is the most convenient in practice, and positions that supplementary lenses are usually fitted, and properly mounted, the best. (3) We expect you would have to get them made to the size. (4) The formula given above is better.

UNSUCCESSFUL SUIT.—J. BAILEY writes: "I enclose herewith cutting from the 'Southampton Observer and Hampshire News' of April 16 last, which I think may interest you. I was plaintiff in the case there reported, and although the defendant did not appear, nor was he defended in any way (except by the judge), you will see that I was unsuccessful in claiming damages. It is evident there was negligence somewhere although according to the judge's ruling in this case it was not negligent of a driver to run over and smash one's camera. The judge's decision notwithstanding, it is still an open question as to whether my operator, who was in charge of the apparatus at the time, or the defendant's driver was guilty of negligence. I shall be pleased to hear your opinion on the matter, and whether you think I have good grounds for appeal, the case being undefended." In reply: As the case was undefended, and the judge decided against you, evidently had a good reason for doing so, as the report of the case proves. Your man was clearly at fault in leaving the apparatus unprotected as he did. As to the question of your appealing, you had better consult your solicitor about that.

COPYRIGHT.—J. SHAW says: "(1) In January last I sold a print to a person to use for his post-cards, no written arrangement entered into as to the use he intended it for, but he said he would issue post-cards, which he has done, as I have seen some of them (I had not this photograph copyrighted). (2) In March I find this same photograph issued by another firm in post-card form (the week following I copyrighted my photograph). This week I find the same firm has issued letter-cards with their name on cover, which they have not applied for in permission in any way for use of same, nor paid me anything. This week they have prepared for sale 20,000 letter-cards ready for delivery to shops in Blackpool. (3) Could you inform me I have any claim on this firm for reproduction by them? If so, should I place it in the hands of a solicitor and ask for a sum, say 20 guineas, and threaten to take proceedings against them if no satisfaction? (4) What would be the cost of such fees I would have to find if I proceeded against them, if I have any case against them, and which way must I proceed? In reply: (1) As the copyright was not registered you have no claim. (2 and 3) You cannot recover penalties for anything done before registration; but you may obtain an injunction restraining sale after registration, and probably damages. (4) You had better consult a solicitor well versed in copyright law. We can give no idea of the costs.

ENSIGN Film Competition.—In order to simplify the entering of photographs for this competition, Messrs. Houghton, Limited, have decided that competitors will only be required to send mounted prints made from Ensign film negatives, and not the films themselves, but they still reserve the right to ask for any film negative from which a winning print is made.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE BRITISH JOURNAL OF PHOTOGRAPHY" JUBILEE NUMBER (1854-1904).

To celebrate the completion of the fiftieth year of the BRITISH JOURNAL OF PHOTOGRAPHY we shall issue on June 10 next a Special Jubilee Number of the publication, which is universally recognised as the oldest and most influential of its kind in the world.

The ordinary issue of the Journal of June 10 will be more than doubled in size in the text portion, and amongst other features will include, by way of supplement, an illustrated history of THE BRITISH JOURNAL OF PHOTOGRAPHY, with Portraits and Biographies of the Eminent Men of Science, Journalists, and Photographers who have been identified with the conduct of the paper during the last fifty years.

As a souvenir of a unique celebration in photographic journalism the "B.J." Jubilee Number will undoubtedly be in enormous request, as it is not too much to say that the history of the paper during the half-century of its existence is most intimately bound up with the history of photography itself.

Of this Special Issue of THE BRITISH JOURNAL OF PHOTOGRAPHY many thousand extra copies will be printed, as the normal demand for the paper will be very largely augmented. Moreover, it is intended to give the Jubilee Number a specially organised world-wide distribution, so that the greatest possible publicity will be secured for the paper on the completion of its fiftieth year of existence.

EX CATHEDRA.

Photography Half a Century Back.

The reprints we have given from the "Liverpool Photographic Journal" (now THE BRITISH JOURNAL OF PHOTOGRAPHY) seem to have taken some modern workers quite by surprise as to the state the art was in fifty years ago, as they had looked upon it that, at that period, it was in a very benighted state. Now, however, they see that it was not so to the extent they imagined. For example, at the meeting of the Liverpool Society, held April 4, 1854, some prints were referred to that were shown in the Exhibition to illustrate 'photolithography, by which it is understood that the picture is first produced by the agency of light on a lithographic stone, and afterwards copies are printed off by the ordinary lithographic process. Of course, at that period the collodion process was in its infancy, but it will be noticed that the advice given to amateurs by one of the speakers is similar to that now given them with regard to gelatine plates. He recommended them not to be impatient to use new formulæ. A person, he said, working steadily with one collodion would meet with more success than if he ran about from one formula to another. If that advice were followed by many amateurs of the present day, who are continually changing their developers, brand of plates, and makes of papers, they would meet with greater success than they are now doing

* * *

Lens Testing.

The discussion which took place on a paper by Mr. Chalmers, which was printed in the March number of the "British Optical Journal," appears in the April number of that paper. There seems to be some hope that the method of testing used at Kew may be improved. The Kew certificates have found very little favour amongst photographers, and very good reasons might be adduced for the fact. But if a new system be adopted, it is of great importance, not only for the credit of the country, but also as a matter of true economy, that the best should be selected. We think it must be admitted that the Hartmann method is the best. On the 22nd April we were fortunately able to publish a translation of a paper by Dr. Hartmann upon the subject, and those interested in the subject would do well to read it. To illustrate the accuracy of the Hartmann system, we may mention three facts. The Hartmann instrument depends largely upon the use of the telescope. If the lens under examination had a focus of 20c. and the telescope of the optical bench a focus of 100 c.c., then the conjugate foci of the two combined would stand in such relation that if the shorter were displaced by 1 mm. the longer will be displaced as much more as the square of the ratio of the focal lengths of the

B

instruments. In this case the ratio is 1 to 5; therefore the displacement of the greater conjugate will be $1 \text{ mm.} \times 5 \times 5 = 25 \text{ mm.}$ The great sensitiveness of such a method must, of course, permit of great accuracy of measurement. Secondly, the ground-glass screen is not used for focussing. What this means may be understood from particulars taken from Dr. Hartmann's previous paper published in *THE BRITISH JOURNAL OF PHOTOGRAPHY* on the 20th February, 1903, p. 146. A series of measurements was made with red, orange, green, and blue light, separately. It was found that the mean error of focussing with the telescope was $\pm 0.062 \text{ mm.}$, whilst a similar series obtained by use of a fine-ground glass screen and a magnifier showed a mean error of focussing of $\pm 0.2 \text{ mm.}$ Thirdly, the errors of the optical instrument used in testing are accurately determined and deducted from the results. If the authorities at Kew are permitted to give certificates expressing the data of a lens, quantitatively, those data should be as accurate as possible. Any doubt about them must inevitably bring discredit upon the Institution. We know that the Hartmann system is used in Germany by certain opticians as a test. Such being the case, what value would attach to a Kew certificate if the standard of accuracy were below that of a Continental manufacturer?

* * *

The Object of Lens Testing.

Whilst drawing attention to this subject, it may be well to point out that the nature of the test should be determined by the work the lens has to perform. This is referred to by Dr. Hartmann in his last paper. In the final paragraph he says that his apparatus is not intended to give information of the kind that usually interests the photographer. More often than not the photographer looks for certain qualities in the lens which have no exact meaning. In such cases a few camera trials will give him more information as to what he requires than a Hartmann test. We might instance as an example the amateurs whose æsthetic ideas are associated with coma and astigmatism, and who are so intolerant of the school which seeks to produce pictures giving the greatest accuracy. The Hartmann tests are purely scientific and tell you in figures the optical results the lens will give. The question might also be asked, Does the user of a lens, in most cases, know what qualities will suit him best? The remarks of one speaker in the debate on Mr. Chalmers's paper prompt us to express the doubt. He is reported to have said "that the exposure was usually made at $f/64$ in photo-mechanical line work, and practically the only advantage of a high-class lens was that focussing could be done at a large aperture. Thick lenses were disadvantageous to process work, owing to the necessary increase of exposure." In the first place, such a statement implies that the majority of photo-line-etchers use lenses of an inferior order or do not understand their use. With a good lens there is no gain, but rather a loss, of sharpness in reducing the aperture below $f/32$ for photographing a line subject the same size as the original. At the same time, it is best to use the same aperture for the exposure as for focussing. If the results are not satisfactory and the greatest accuracy is required, then the focus should be found by trial and error. Thick lenses, of course, imply a certain loss of light from absorption, but if "thick lenses are disadvantageous," why should the only practical advantage of a high-class lens be "that focussing could be done at a large aperture"? Would not the loss of time in exposure be compensated?

* * *

Ancient Lights.

The question of "Ancient Lights" is one that is interesting to photographers in, perhaps, more ways than one. If the light

in their studio is blocked out by some new building it becomes a very serious matter to them particularly if they can obtain no compensation for the injury done, and in many instances that is the case. In other cases the question of "ancient lights" may be interesting to them from quite a different point of view, that is, when they are called upon, as a matter of business, to take photographs of buildings and their surroundings; in law cases, where the question of ancient light lead to litigation; then it brings grist to their mill in the shape of substantial fees for their work. It may here, perhaps, be well to explain to many what is the law with regard to ancient lights. Any one can erect on his own premises anything he likes, regardless of the light he may stop off from his neighbours, provided the neighbour's unobstructed light has not been enjoyed for more than twenty years. If it has, then putting up anything that will obstruct it becomes illegal, as he is entitled to retain, unobstructed, his ancient lights, and he can obtain an injunction to restrain, or recover damages. We know of several cases where photographers and others have obtained very substantial damages where their ancient lights have been interfered with. A case of very great importance in connection with this subject was decided one day last week in the House of Lords by the Lord Chancellor and other Lords. It was an appeal from a judgment of the Court of Appeal reversing an order of Mr. Justice Joyce. It involved an important question of obstruction of ancient lights, and had twice been argued before their Lordships. Briefly stated, the case was this, as we gather it from the daily Press reports of the case. A building was put up that obstructed the light that had been enjoyed for over twenty years, and it was sought to have it pulled down. It was not contended that the new building would not stop off more light than the old ones did, but the appellant contended that the amount of light that would be left would be sufficient for the respondent's business in ordinary trade, and this was the view taken by the House of Lords. The Lord Chancellor, in delivering judgment, remarked that if the respondent could restrain in the way he thought he could, and the Court of Appeal had decided that he could, towns could not grow, and expansion would be unduly restricted. In the end judgment was given for the appellant with costs, and costs in the Courts below. It should be kept in mind, in this case, the respondents were a firm of grocers, the "Home and Colonial Stores," and the new building still left them sufficient light for their ordinary business purposes. Had the case been that of a photographer it might possibly have ended differently. A certain amount of light stopped off from a grocery establishment may not materially interfere with the carrying on of the business. But in the case of a photographer it might be widely different, as any material obstruction of his studio light might, especially in confined spaces, seriously effect the quality of the work he produces.

The Royal Academy and Sartorial Art.

The Royal Academy Exhibition was opened to the public on Monday last week, and it has been exceedingly interesting to read the critiques on the pictures shown that have appeared in the daily Press, and the diversity of the opinions expressed on their merits. We always look forward with interest for what our good friend the "Tailor and Cutter" has to say about the paintings of portraits in the annual show, and this year it is, as usual, very severe on many of the artists. Here is an example: "After carefully inspecting the pictures of the year, we have come to the conclusion that many of the painters cannot draw with any degree of accuracy, and some of them blend their colours in such an

original way that they border on the grotesque." Our contemporary then goes on to criticise some of the pictures in detail. One is Professor von Herkomer's portrait of the Right Hon. Joseph Chamberlain. Of this it says that an "at breast pocket is placed too low down, and the coat has but one button, and the vest two, that are far too large, the collar of the coat is too heavy, and the lapel is veryumpy. Mr. Chamberlain's trousers also come in for condemnation; they are said to be not of a good colour, being strongly suggestive of inferior material, worn too long, and which has, consequently, turned a greeny brown, whereas the protected parts are black. Nevertheless, Mr. Chamberlain's clothes are better than those of Mr. Goscombe John, A.R.A., as depicted by Mr. Arthur Hacker, A.R.A., in No. 3. The sculptor's coat is a smudge of black and has no buttons. These are also missing from the vest, which overlaps one way at the top and another at the bottom. Bad, too, are the coats of Mr. Russell J. Kerr, M.P., painted by Mr. Frank Bramley, and of Sir William Emerson (119), for which Mr. Shannon is responsible. According to the tailor-critic Sir William's frock-coat has, among many other faults, no collar on the right side, and the outside edge to the lapel is "like a dog's hind leg." But the severest criticisms are reserved for Mr. Seymour Lucas, A.R.A., whose holiday in Spain will be overcast with gloom the "Tailor and Cutter" circulates in the Peninsula. Mr. Lucas's portrait of Sir John Neilson Guthbertson, the leg-coverings (he refuses altogether to call them trousers) fill the critic with despair; from the tailor's point of view he has seen nothing so bad. It would most seem to be the idea of the "Tailor and Cutter's" critic that men were made for tailors. He did not tailors for men, and that every one could be clothed according to the tailor's notions and in accordance with the wearer's comfort. If, however, the wearer has his garments made according to his liking, and the artist portrays him in such clothes he must expect rating from the sartorial organ. Why do not artists, before attempting to paint a portrait, study the dummies shown in clothiers' windows, and their "graceful" poses; they would then escape the ire of the "Tailor and Cutter," speaking of painters not being able to draw with any degree of accuracy, it may at once be admitted they cannot, that if the fashion plate issued with the number of our contemporary that contains the strictures on the R.A. pictures, is to be taken as its criterion of art. The drawings of that, and the pose of the figure is—well! But after all we must, we suppose, accept it as the sartorial ideal of Art.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon (the 9th inst.), the Duke of Northumberland, K.G., President, in the chair. The Chairman announced that he had nominated the following Vice-presidents for the ensuing year:—Sir William Abney, K.C.B., Mr. Alfred Bidwell, Right Hon. Lord Kelvin, Dr. Ludwig Mond, Sir Thomas H. Sanderson, G.C.B., Sir Felix Semon, Sir James Crichton-Browne (Treasurer), and Sir William Crookes (Honorary Secretary). The following were elected honorary members:—Professor E. H. Riefler, Professor J. M. Crafts, Professor E. W. Morley, Professor C. Pickering, Professor L. P. Cailletet, Professor and Madame Curie, Professor H. L. Le Chatelier, Professor G. Lippmann, Professor J. W. Bruhl, Professor G. H. Quincke, Professor E. Fischer, Professor F. W. G. Kohlrausch, Professor H. Landolt, Professor L. Boltzmann, Dr. H. Kamerlingh Onnes, Professor H. A. Lorentz, Professor G. Lunge, Professor P. T. Cleve, and Professor P. Zeemann. The special thanks of the members were returned to Mrs. Frank Lawson and to Sir Thomas Sanderson, G.C.B., for their donations to the fund for the Promotion of Experimental Research at Low Temperatures. The following were elected members:—Mr. P. M. Brophy, Mr. W. J. Canter, Mr. Eyre Crowe, Mr. H. T. Ellis, Miss E. Morgan, Mr. Berkeley Portman, and Mr. Burnett Tabrum, J.P.

DIAGRAM LANTERN SLIDES.

II.

WHEN dealing with this subject recently we made a half promise to give further hints on the making of this particular class of slide—a promise we now proceed to redeem. Slides, where there are no half-tones, no picturesque features to occupy the mind, nothing to lead the observer's attention from trivial irregularities or spots that may be present in broad expanses of pure white, require a delicacy of handling and a care in every stage of their production, speaking, of course, of their mechanical manipulation, far in excess of what is needed for an ordinary view-slide. The tiniest speck of dust, a broken line instead of one crisp, sharply-cut and even, a slight stain due to the use of plates kept too long, are fatal departures from perfection; they attract and distract attention—to the defect and from the lecturer's remarks. No one but an experienced lecturer knows the annoyance of seeing or hearing whispered comments or heads brought together or in disparagement of a slide so departing from a high mechanical standard. Nowadays there are always a number of photographic amateurs in every audience, who, if their skill in slide-making equalled their power of fault-finding, must be among the most able experts who ever handled a camera or developed a plate, or, more especially, pressed a button. The only method of over-reaching them is to produce a perfect slide. The method of giving white lines on a black ground overcomes many difficulties; but, as the photographer has mainly to carry out his client's instructions, and as the white ground is still generally adopted, he will have no choice, and will have to supply the "usual thing." To avoid broken or uneven lines, correct exposure in making the negative is necessary, and is also very helpful in obtaining solid blacks; an under-exposed plate is difficult to get thoroughly opaque, and is liable to give grain, through showing the texture of the paper. We have seen many slides defective through imperfect definition at the margin, a fault very liable to occur when copying a small original. The virtues of a modern anastigmat are conspicuous here; but, as many photographers do not yet possess such a lens in their outfit, they must obtain the needful crispness of line by well stopping down their lenses of the old type, and avoid grain by careful and even illumination and full exposure. Where slide-making is frequent it is highly desirable to use a special plate—either a "process plate" or, which is still better, a "photo-mechanical plate," some manufacturers producing both kinds, the latter being the slower still, but giving the greater density. It is, however, in the production of the transparency (and here also the use of the special plates named is of advantage) that particular care is necessary. Our recommendation to make an over-dense slide, and clear it by the reducer is important, and has the further advantage of giving such perfect transparency in the whites that if occasion arise to use the knife to pick out a dust spot, or to remove a line or letter, it can be done without showing the erasure on the screen, as would be the inevitable result if grain or the faintest greyness in the white ground were present. A single experience would teach this without instruction; but it is well to refer to it for, as such patching would usually be done afterwards, the experience would be bought dearly, as either an imperfect slide, or the reprinting, when perhaps everything had been put away, would result. A further hint may be here given. Particular care should be given to the washing, as this stage is fruitful in the deposition of small opaque particles, which could never be seen in a view, but which put with large expanses of white, would at once be noticed. Hence the plate, before being placed in the rack to dry, should be carefully rubbed with a pledget of wet cotton-

wool, and care be taken that no dust be raised in the drying apartment, and, above all, that the slide be not placed resting on a shelf or table, as any possible dust particle would instantly be drawn up by surface tension, and probably deposited in a conspicuous portion of the diagram.

We may here observe that, not only for lantern slides, but for all negatives, especially portrait negatives that are to be afterwards retouched, a plate is far better put to wash upright in a tank than horizontally under the tap.

Surface stains, from an over-kept plate, and showing, by reflected light, iridescence which would not matter, and by transmitted light a yellowing of the whites which would matter, are easily removed by rubbing with cotton-wool, wetted with a very dilute solution of ferricyanide—one grain to the ounce is ample for the purpose.

A remarkably effective slide, which is of the nature of a diagram, is made by taking from a half-tone process-block print an enlarged photograph of, say, the head only of a popular character, and of such size as to fill the screen. A series of dots only will appear, with scarce a semblance of features. The same head can be next shown on a smaller scale when, of course, a proper representation of a face will be seen, the tones being produced by dots of various sizes. If the block is available, time and trouble will be saved by getting the printer to pull a print on to a waste celluloid dry-plate, from which the image, or the silver-salt, has been thoroughly removed. An excellent negative may thus be produced. A chloride film fixed thus gives the clearest transparency.

When anything has to be added to a finished slide, either by altering a diagram or writing a title or explanation, as simple a plan as any is to scratch deeply with a sharp needle, rub fine lamp-black in, or what is more readily obtainable, the powdered "black chalk" (known among artists as stumping sauce), finishing by removing the surplus black with a camel-hair duster, and not by blowing it with the breath, which would tend to become "dirt"—that is, matter in the wrong place, as Lord Palmerston is credited with calling it. If Indian-ink be preferred, it should be freshly rubbed up, and if it requires moistening, on no account must it be wetted by the mouth; it then would inevitably run "clotty." The addition of a little oxgall makes Indian-ink "bite" well.

Where slight alterations or additions are required to a slide, much may be done by treating the surface with retouching medium, and adding what is necessary by means of the usual finely-pointed lead-pencil.

Occasions may arise when a copy of a process-block print is wanted in a hurry. A good result may be obtained by getting a print on celluloid as just explained, or it may even be made on thin tracing-paper, pasted upon glass, and then varnished. An emergency slide can be made out of an albumenised paper print. It should be placed for a while in boiling water to remove as much of the size as possible, then pasted on to the glass, and well dried, and finally heated and rubbed while hot with a piece of paraffin (a piece of paraffin candle will answer the purpose admirably).

We may now conclude our survey by concentrating our advice. If perfection of slides is aimed at, obtain fully-exposed negatives and scrupulously clear transparencies.

BEAUTIFUL peeresses and actresses are expressly excluded from the latest beauty competition on the ground that they already enjoy a monopoly of the "beauty pages" in the leading magazines—"Sketch," "Tatler," etc. Messrs. Gee and Watson, of St. Bride Street, London, are offering a prize of five guineas (and three guineas to the photographer) for the photograph of the most beautiful woman in the United Kingdom (not titled nor an actress) which they receive before the end of May.

AMERICAN NOTES AND NEWS.

HAND CAMERAS AT THE WORLD'S FAIR.—Intending visitors to the World's Fair will be interested to know (writes "Wilson" that official notice has been received by the Eastman Kodak Company to the effect that hand cameras up to 4 in. by 5 in. size will be admitted to the ground without charge, but cameras may not be used with tripods, however, but must be literally hand cameras. It is but fair to add that the effect of the Eastman Kodak Company toward the acquirement of this concession have probably had much to do with bringing it about. The coming Exposition will be the first in the country that has viewed the matter of photographic concessions from the hand camera workers in this spirit of breadth and liberality, and we opine that the management will have no reason to regret having made the concession. Its effect upon the Exposition ought to, and we believe will, be distinctly good from an advertising standpoint, and its value to the visitor who desires to take away with him interesting, instructive, and otherwise valuable records of the great meeting will be inestimable.

NEED BIG CAMERAS.—Modern warfare does not really lend itself to photography. Action nowadays is too spread out unless under extraordinary circumstances, for one to get much of it within the scope of any camera. The new panorama camera has promising possibilities (says a contributor to "New York News"), but even that will fail in most cases. I went through two wars before I succeeded in getting a good picture of real fighting. Soldiers are taught now (and good teaching is, too) to conceal themselves as much as possible while in action, even when not actively participating in any movement. The immense range of modern firearms means that a given area is swept with projectiles during a battle, and troops to within supporting distance are generally well within range and lie down when not in motion. Then, much depends upon the character of the terrain. I have often been right with troops on the firing line, with my camera in my hand, and yet waited for hours before I could get a single picture that promised any adequate photographic results.

THE POSE OF THE HANDS.—"W. E. W.," in "Wilson's Photographic Magazine" for April, points out that one of the greatest difficulties in posing hands has been the nervous consciousness of the sitter; but this fact is, fortunately, becoming a thing of the past. The greatest troubles nowadays are the slight exaggeration of the short focus lens, and the belief in many minds that hands are smaller than they really are. Do (he adds) let the sitter hear a word about her hands—try to let her forget them. Do not let the hands be placed symmetrically, so that the head looks like the apex of an isosceles triangle. Hands look more prominent on dark dresses than on light ones. A hand may be partly hidden by the fold of a dress, or its size may be apparently reduced by placing it sideways to the camera. If it is a natural pose, a hand supporting the cheek or chin usually looks well. If the fingers are relaxed, the hand looks smaller and more natural than when the fingers are stiff. Treat each pair of hands on their merits, usually by leaving them to the natural unconsciousness of the sitter, and the difficulties of posing the hands will to a great measure disappear.

NON-CURLING GAS-LIGHT PRINTS.—In order to prevent prints curling, Mr. Milton Wade, in the "American Amateur Photographer," makes the following practical suggestions: Lay out blotters. On these place muslin from which starch has been washed out, and keep the muslin for just this purpose. Take prints from the wash water and lay face down on the muslin. When prints are just dry enough so that films will not adhere, and yet while quite damp, they are rolled film out, around a roller 1½ in. to 2 in. in diameter (I use

piece of background roller, the sort they are shipped round), then a small rubber band is placed round each end and the roller removed, leaving a circular form of the rolled prints. All are prepared in this manner and takes less time to do than to tell, and they are allowed to become stone dry while in this shape, thus allowing the pores of the gelatine film to stretch. The rubber bands are then removed, and if necessary three or four prints at a time are rolled the other way around the roller to make them lie flat. Having been stretched while drying they will not curl again. I find it advisable, when heavy paper with smooth surface is used, to, before placing on the roller, curl the ends of the print backwards with a ruler, to prevent the sharp edge marking across the face of the print during the drying process.

BACKGROUNDS.—It has often occurred to us: Why do the background painters paint their subjects in a blurred way instead of making the objects composing them definite and distinct? Look, for instance, at a professional portrait with a scenic background (remarks "The Camera"), and if you have any artistic feeling, and have not been led by habit to admit such conditions, you will perceive at once the incongruity of the arrangement. When you look at a person in the woods, with the natural trees behind him, your attention is by no means specially attracted to the background, simply because the person is in harmony with the scene. The trees or shrubbery nearest to him have more or less distinctness; the distant objects only are hazy and blurred. If the near objects should appear to you blurred, your attention would be forcibly attracted. It would seem to you unnatural, unreal, and yet it never strikes you as unnatural when you pose a figure before an all-over blurred scenic background. Now, when you consider further that in making a portrait you usually place your subject some distance from the background, and are anxious, for obvious reasons, to get your subject sharply defined, with no desire to sharpen the background, so that you have it considerably out of focus, thus adding further to the blur, why not employ a background in which the foreground is definitely represented—painted with accuracy of detail and true perspective, aerial as well as linear. Scene painting, of course, is an art peculiar to itself, and requires a different handling from a painting which is intended to be viewed at a short distance only; but there is no reason for the conventional way they are painted.

PERSONALITY IN PORTRAITURE.—I was talking to a brother photographer the other day, and as we rattled along on various topics of photography my friend casually remarked that he made pictures from a photographic standpoint, that he did not care what he could get a well-finished picture, but that the latter had to get the expression. "Now, my friend," said I, the "I" being Mr. A. W. Franklin, in "The Photo-Times Bulletin"), "if you should go to a doctor to have him cut off your finger, and he told you in the most matter-of-fact way to have a seat, and then proceeded to cut it off without offering to administer gas or chloroform, without giving an encouraging word or look of sympathy, would you be attracted to him; would that kind of dealing appeal to you? Could you recommend him to your friends, and do you think that doctor could make a success?" When your sitter walks into the studio she naturally needs sympathy. Let us suppose she has never entered one before; can you reasonably expect her to be composed, to have a pleasant expression, if you do not make any effort to entertain her, making her feel at ease? Show your sitter that you are especially interested in getting a good portrait; if not, can you expect to get a natural expression? We are governed greatly by our surroundings, and when we are in strange places, and have strange duties to perform, we feel uncomfortable. We hope for sympathy and a kind look or word from some one will make us feel more at ease. If a

photographer can realise this, and will give his customer a hearty handshake or a word of welcome, he is no longer a stranger. I was once making some negatives of a friend, and while I was picking up the plateholder he said, "Take it quick, while I am myself." I made the exposure and several others, but he insisted that he was in one picture only.

THE SINE AND TANGENT CONDITIONS AS AFFECTING PHOTOGRAPHIC LENSES.

[Translated from the "Zeitschrift für Wissenschaftliche Photographie."]

IN recent publications concerning geometric optics, the relation to one another of two conditions, the so-called sine condition and tangent condition, has either been totally neglected, or treated in a very indistinct manner. But a clear statement of their relationship is very necessary, as these two conditions play a very important part, for instance, in the construction of photographic lenses. As the constructors of these are not always thoroughly educated mathematicians, it is not surprising if they are sometimes wanting in definiteness of thought upon matters connected with these conditions. Such a shrewd mathematician as Herr Thiessen believed he had proved in his treatise, "Contributions to Dioptrics,"* that Professor Abbe in comparing the sine and tangent conditions had mistaken two different angles. Professor Abbe, on the contrary, had only in view a strained and unusual employment of a microscope objective in the statement instanced by Herr Thiessen.

In the following remarks I will endeavour to show in a way that may be generally understood, whether the sine and tangent conditions stand in definite relationship to each other or not, so far as they concern photographic lenses. For this purpose we will take an optical system surrounded by air, that is to say, both contacts, front and back, are with the same medium, air. Photographic lenses are optical systems of this kind. We will then define separately the two conditions.

The sine condition demands that all rays proceeding from an object-point, situate on the axis, shall converge in such a manner, after their passage through an optical system of finite aperture, that the relation of the sines of the angles, formed by the rays with the axis, in front of, and behind, the system, is constant:—

$$\frac{\sin u}{\sin u'} = \frac{\sin \alpha}{\sin \alpha'} = \text{constant.}$$

The error which arises from non-fulfilment of the sine condition is therefore one of the image point situate on the axis. It only occurs in a system of finite aperture, and the photographic objective is such a system. The distribution of light in the image point is no longer symmetrical; that is to say, in the disc, representing the point in the image at the picture plane, the light is no longer arranged in the same order from centre to margin, as it is where it strikes a circle situate in the plane of the front vertex of the optical system. For this reason this error was called deformation by A. Steinheil, who, as is well known, satisfied the sine condition in all the photographic lenses he constructed.† It was consequently known to him long before it was baptized.

* Sitzungsberichte der Royal Prussian Academy of Science, Berlin, vol. xxxv, 1890, p. 18.

† See M. von Rohr's "Theorie und Geschichte des Photographischen Objectives," 1899, p. 307.

with its present name. Charlier, no doubt for the same reason, called the sine condition the symmetry condition.

To repeat, therefore, the sine condition is concerned with the various rays which proceed from one point in the object, which point must be situate upon the optical axis, and the system upon which the rays are incident must be of finite aperture.

The tangent condition demands that the principal rays proceeding from different points in the object, in a plane perpendicular to the optical axis, shall emerge from the optical system, so that the relation is constant between the tangents of the angles they form with the axis, in front and behind the system.

$$\frac{\text{tg. } \omega}{\text{tg. } \omega'} = \frac{\text{tg. } \chi \lambda}{\text{tg. } \chi \lambda'} = \text{constant.}$$

A ray which passes obliquely through the optical system, without refraction, I call a principal ray. Or, in other words, a principal ray is one which forms the same angle with the optical axis, both before and after its passage through the system. In oblique pencils of light the principal ray plays the same part as the axial ray in the axial pencil. It passes through the system without refraction.

The error which occurs through non-fulfilment of the tangent condition relates to surface. It only occurs when the object is one of extension, and its consequence is that the image does not resemble the object. The drawing of the former is incorrect, and the error is consequently called distortion. It is not necessary that the aperture should be finite. Distortion occurs rather with very small apertures. The characteristic of the tangent condition is that it relates to principal rays.

If we wish to picture to ourselves when the sine and tangent conditions should be simultaneously satisfied in one point, this would be the case if principal rays of the system fell upon one point, for which the sine condition was satisfied. But, according to our definition, a point in the object, for which the sine condition is satisfied, must be upon the optical axis. Only one principal ray can fall upon a system through an axial point for which the sine condition is satisfied, and this single principal ray is the optical axis, for it is the only ray which can traverse that point, and then pass through the system without refraction. Consequently, there can be no question of tangent condition, regarding a point in the object, for which the sine condition is satisfied. If aplanatic points are defined as those for which spherical aberration is corrected and the sine condition simultaneously satisfied, then there are only aplanatic points upon the axis. As we have already said, there is no question of tangent condition regarding any object points situate on the optical axis, consequently a contradiction between sine condition and tangent condition can never occur. Confusion can only happen when rays, otherwise defined, are called principal rays. The observant reader will meet with this in the most diverse of recent literary productions. As one instance only, we may mention the description in Dr. J. Clasen's "Mathematical Optics," paragraph 53, page 111, which certainly cannot be understood generally.

DR. R. STEINHEIL.

February 7, 1904.

LIGHT IN CRYSTALS.

[From the "Scientific American,".]

RAYs from a sacred ruby are fabled in the Rabbinical legend to have lighted the ark of Noah. The idea of a crystal as fountain of light has been in all times congenial to the poet's imagination, and nature is less averse to poetry than is sometimes supposed. Many crystals shine in the dark, and some very pretty experiments showing this may easily be made. Many diamonds are thus luminous—a property which may enhance in our eyes the value of these precious stones. rubbed with a woollen cloth or against a hard body, they appear surrounded with light. In particular, the pretty experiment is recommended of rubbing a diamond upon gold, when it shines "like a burning coal excited by the bellows." Friction while frequently aiding luminescence, is not its true cause. The essential condition of shining is previous exposure to light. The gem has been lying in the sun's rays, and these it has imprisoned, and now sets free in the dark. The sunbeams of Laputa were stored up in cucumbers; the real sunbeams are more fittingly stowed away in diamonds, and the crystal prism acts as though because the light it holds is of no mere earthly fire goes on shining even under water, like the fairy palace under the sea. In warm water, indeed, the light becomes brighter or may be made visible when not otherwise so. We read that in the thirteenth century the alchemist Albertus Magnus saw a diamond which shone when it was put into warm water, and this indicates the early discovery of an important law. In all cases where bodies shine after exposure to the sun, heat hastens the emission of light. It does not increase the total amount of light emitted, for though the body shines more brightly in proportion to the rise of temperature, yet the light lasts a proportionately shorter time. Borrowing a metaphor from coarse material things to describe this truly ethereal phenomenon, it has been said that the phosphorescent body soaks up light like a sponge, and heat squeezes it out.

The effect of friction on phosphorescent diamonds has been proved to be independent of electricity, and may be a modified form of the heat effect. Some facts, however, would seem to render this doubtful, as when Dana, speaking in his "Mineralogy" of the phosphorescence of sulphuret of zinc blende, says: "Merely the rapid motion of a feather across some specimens will often elicit light more or less intense from this mineral." The effect of friction in disentangling the imprisoned light may therefore appear to be still mysterious. The property of phosphorescence in diamonds is very capacious. Dr. J. W. Draper, in his Memoir on Phosphorescence, relates that a lady who was a relative had a pair of earrings in which were set two large and beautiful diamonds, both of which he found to be phosphorescent. They shone after exposure to the electric spark, which here took the place of sunlight. She had another pair, and the diamonds in both of these phosphoresced also. Yet in the necklace belonging to this set, containing thirty-eight fine stones, only one was phosphorescent. These were white diamonds. A yellow colour would seem more favourable; thus Du Fay found that of four hundred yellow diamonds all were phosphorescent, while some that were white, rose-coloured, blue, or green were not. We cannot always experiment freely on diamonds, but we may obtain equal beautiful effects with fluorspar crystals, especially those of the variety called chlorophane. A crystal of chlorophane, dropped into water nearly boiling, spreads around it a soft light like that of a glow-worm in the grass on a summer night, delicately tinged with olive green, and illuminating beautifully the transparent form of the crystal. Or the fluorspar may, after dark, be placed on the kitchen stove. It soon becomes visible by its pale glow, then brightens till it seems filled to overflowing with the soft green-white light. The reader cannot be advised to try these experiments on his fine cabinet specimens, for if they be more than slightly heated, they will be cracked and

coloured. Ten or twenty cents' worth of broken crystals may be bought of a dealer in minerals, and the following very pretty experiment made:—The pieces are ground in a mortar and some are powdered, others remaining of various sizes. They are then sprinkled on a sheet of iron that has been heated somewhat below red heat in the colourless flame of a Bunsen burner—the experiment being of course done in a perfectly dark room. The fragments begin at once to shine, growing rapidly brighter. They pass through a fine series of colour changes, the order of colours varying in different specimens. They may have greenish-white or orange changing to light blue, then rose colour, then violet, which, passing through shades of deepening blue, finally becomes dark. The fine powder changes more rapidly than the coarser bits, so that the sheet appears strewn with rainbow colours. Some green fluor used by the writer gave a beautiful effect, the crystal dust turning quickly to an exquisite rose colour, while the unbroken rectangular crystals shone like elfin lanterns, casting around a fine illumination—olive-green, orange, or blue.

Colourless or very clear fluor crystals ordinarily shine feebly, not at all; besides, the green, the violet, and blue generally shine well. Draper had a pale, flesh-coloured crystal of chloroform, which excelled all his other specimens in the splendour of its light. It shone of a superb emerald-green colour after receiving the rays of the sun. The warmth of the hand in a dark place made it shine. There is no fixed relation between the colour of the crystal and the emitted light. At the moment when, after heating, the crystal becomes dark, its colour is permanently discharged. There is also decrepitation, on which account it may be well to screen the operator's eyes. If, in performing the above experiment, the reader grinds the crystals in the dark, he will see that eddies of light follow in the cracks of the pestle. Breaking, scratching, or cleaving a crystal is another mode of eliciting the light it holds thus "veiled in its transparency." Fluorspar is phosphorescent both on heating and by cleavage; other crystals may be phosphorescent by cleavage, which on heating shine little or not at all. While packing up oyster-shells on a block of white marble of the variety called dolomite, the writer was one evening surprised by a flame-coloured glow appearing where the dolomite was struck by the hammer. This spot in the white stone shone like kindled coal, creating the curious impression that the stone was becoming red-hot under the hammer. It was, however, not hot to the touch. The effect was at first supposed to be due to the oyster-shells, which are well known to yield, on polishing, the phosphorescent calcium chloride. It was, however, found that the dolomite, which came from a neighbouring quarry at Hastings-on-Hudson, was phosphorescent independently of the oyster-shells. It is well known that some dolomites have this property. A piece of the stone, rubbed with another, or scratched with a sharp instrument, shows in the dark flashes or streaks of fine orange light. Harder pressure or a smart blow of the hammer gives a flame-red glow. The orange streak is nearly instantaneous, but the reddish glow remains a moment before dying out. Pieces of ordinary hard and fine-grained marble do not phosphoresce, and among dolomites the softer varieties with large crystals give the best results. More lively in its manifestations than this dolomite is a kind of stone found in northern New York, and called significantly "hell-fire rock." Anyone scratching with a sharp instrument a piece of this sulphurous-looking stone will see, in the dark, the true Mephistophelean fire. The streak is yellow, resembling that of sulphur matches.

The most beautiful exhibition of this kind was made by rubbing together briskly two fine pieces of rose quartz. The crystals, each the size of one's fist, were completely illuminated by brilliant flashes, which shed a light around, rendering the operator's hand visible. The flashes were instantaneous, resembling the illumination from electric sparks. The colour

of the light was generally white or light yellow, but sometimes the crystals sparkled orange colour when their angles struck together and chipped. The experiment was of course most conveniently made by rubbing together broken surfaces of the crystals, so as not to impair handsome specimens. Smoked quartz and other varieties gave sparks as well as the rose. In making the above experiments an accident illustrated how it so often happens in the history of science that the investigation of one thing brings another to view. In the dark a finger was inadvertently thrust through a hole in the broken mica chimney of a drop-light, whereupon the bent edges of mica emitted a faint flash of light. The edges of the sheet must be struck obliquely, for it is the cleaving of the thin laminae of the mica crystals which causes emission of light. It is interesting to note that the separated laminae possess charges of opposite electricities, although from other evidence we suppose the phenomena of light and electricity independent. Phosphorescence on cleavage is a property of a number of other crystals. The interesting case of loaf-sugar has been described in a former number of the "Scientific American." The most beautiful example of all is said to be the phosphorescence of nitrate of uranium crystals. Each crystal broken in the dark is all lighted up, and, provided they are thoroughly dry, it is only necessary to shake up a bowl or bottle of the crystals to cause a splendid display. This is of especial interest on account of the connection of this substance with the discovery of radium. Seeing that the shattering of the crystalline bonds causes emission of light, one naturally inquires whether crystals ever give out light in forming. We find that some crystals do, a most beautiful illustration being found in the crystallisation of arsenious acid, the common "white arsenic" of commerce. As this experiment requires some laboratory apparatus, and as success in it involves careful attention to certain details, it is reserved for a future article. A solution of the substance, properly prepared and set to cool slowly in the dark, sparkles as each tiny crystal forms, while the effect on shaking the solution resembles a fine display of the phosphorescent light at sea.

It is said that molten silver phosphoresces at the moment of solidification, and that water, when made to freeze with great rapidity, emits a flash of light clearly visible in the daytime.

A. C. MAURY.

SOME SPECTROSCOPIC EXPERIMENTS WITH TRICOLOUR FILTERS.

[A Demonstration given before the London and Provincial Photographic Association, April 28.]

OBJECT of the Experiments.—I propose to bring before you this evening a means of testing the filters, plates, and printing colours used in trichromatic photography. This method is most readily applicable to processes such as Lumière's or Sanger Shepherd's where the final colour print is in the form of a transparency. The test consists essentially of a comparison between colours photographically selected from a spectrum of white light by the filters and plates and the colours of the dyes used to reproduce them.

Manner of Reproduction of a Spectrum.—We will firstly consider how a spectrum of white light may be reproduced by a tricolour process. For this purpose we will divide the spectrum into five regions—viz., red, yellow, green, blue-green, and blue-violet. The yellow and green regions will be narrow. The colour filters and plates should be so adjusted to each other that the red negative should record the red and yellow regions, the green negative should record the yellow, blue-green, and blue-violet, and the blue negative the blue-green and the blue-violet regions. That is to say, these regions will be recorded by a silver deposit—the negative—and in printing from these negatives in pigments, the pigment will in each case be printed upon the regions not recorded in the particular negative being

used and should therefore be one which is transparent to all the colours of those regions, while absorbing the colours recorded. According to this argument the printing colours should be as follows:—For printing from the red negative: a pigment absorbing the red and yellow of the spectrum and transparent to the green, blue, and violet. This colour will be a greenish blue. For printing from the green negative: the pigment should transmit the red and violet and absorb the intermediate regions. The hue of this will be crimson. For printing from the blue negative: a yellow pigment should be used that is transparent to the red, yellow, and green regions and opaque to the blue-green and blue-violet.

The reproduction of the spectrum will then be made by printing these three colours in succession from their respective negatives. In this reproduction it will be noticed that the regions of the three primary colours, red, green, and blue-violet, each of which was only recorded by its own particular filter and plate, are reproduced by the superposition of the printing colours in pairs. That is to say that the red region, for example, which is recorded only in the red negative, is in the reproduction rendered by the superposition of the printing colours of the other two negatives, viz., crimson and yellow. Now, the crimson absorbs the yellow, green, and blue-green of the spectrum, and the yellow pigment absorbs the blue-green and blue-violet. So that the only colour that can pass through them both is the red. This region is therefore reproduced by a uniform hue of its own mingled tints. In the same way, the green and blue-violet regions are rendered by the superposition of the greenish-blue and yellow pigments and greenish-blue and crimson pigments respectively, and they are of a similar nature, that is, they consist of uniform hues made up of the mingled light of their own regions. The yellow region recorded by both the red and green filters is reproduced by the yellow printing colour of the blue negative, and the blue-green region is rendered by the printing colour of the red negative. The division of the spectrum into five regions should be so made that these latter pairs of colours match each other as nearly as possible.

Apparatus.—The apparatus used consists of a spectrum camera in which a nearly normal spectrum is produced by means of a prism-grating. An image of this may be projected on the screen by means of a large lens or by moving the lens back so as to focus an image of the grating the colours are combined again to white. Photographs may be taken of the spectrum by this apparatus, and then optical experiments made with them. A beam of white light is diverted by means of an unsilvered mirror, and in this comparison colours can be placed.

Nature of Complementary Colours.—I now wish to demonstrate that the term complementary cannot be regarded as a full and sufficient description of the relation of the printing colour to the colour recorded in the negative. This blue colour which you now see on the screen consists of that part of white light which is recorded by a blue negative, and here is a yellow light which, when mixed with the blue, gives the appearance of white. These two are therefore complementary. If we now form the spectrum of the yellow we find that it consists of only a narrow band of the spectrum. Here is another yellow, which, as you see, also forms white when mixed with the blue. But its spectrum tells us that it consists of pure red and pure green lights only. A third yellow answering the same test comprises all the colours not recorded by the blue negative, and this is the only one which would be of any use in tricolour printing. So that the printing colour must not merely be complementary, but must with certain reservations consist of all the colours not recorded in the particular negative.

A Direct Test for the Complementary Condition.—If a contact

transparency be made from a filter record of a spectrum, and this placed back in the spectrum, it will allow to pass only the light originally recorded. And if a gelatine film dyed with the printing colour be placed by the side of it in the spectrum, and the transmitted light be combined to a uniform patch; this patch can be made white by a slight lateral adjustment of the two if they are complementary. This experiment is not very satisfactory with the apparatus I am using to-night. The reason is that the chromatic aberration of the condenser is sufficiently great to give a red fringe to the cone of light thrown on the collimating lens, with the result that a little of this is lost and the white patch produced by recombining the spectrum is a trifle too violet, so that it does not exactly compare with the reflected white beam.

Different Effects of Filters in Copying Light and Dark Colours.—I cannot show you to-night the varying effects which some filters have in reproducing light and dark shades of the same colour, but I can show you the variations in the record of the spectrum of white light by comparable variations in the exposure. Ives' Red Filter, for example, records with medium exposure the red and a little of the green, while, with fuller exposure (25 times) as much green as red, so that this filter will act differently in copying different parts of the same picture. Another series which I have shows but very slight variation in the character of the record with exposure. This is one of the filters in use at the Bolt Court School.

Comparisons of the Visual Colours of Filters and the Colours Photographically Recorded, and Comparisons of the Printing Colours with the Theoretical Colours.—The variable effects we have just seen which occur with some filters form a disturbing element in any such experiments as these. In dealing with filters such as Ives', perhaps the best photographic record to take are those which (with exposures given in the ratios of the camera exposures) appear during development at the normal time. The negatives of the experiments I am about to show you were made in this manner. A contact transparency from the negative is placed back in the spectrum, it therefore allows only that light to pass which was originally recorded; by combining this light to a uniform patch its hue may be compared with the visual hue of the filter placed in the white beam of light. And the instances shown will demonstrate the uselessness of any visual test in this class of work. By placing back in the spectrum the original negative the colours there recorded will be stopped, and, according to my ideas, the light transmitted should be the same as the light transmitted by the correct printing colour, which in cases of comparison may be placed in the white beam.

For greater convenience these experiments are published in tabular form:—

Filters.	Visual Colour.	Colour Photographed (positive in spec.).	True printing complementary. (Neg. in spec.).	Printing colour used.
Ives	Orange.	Lighter orange.	"	"
	Yellow-green.	Yellow-green.	"	"
	Greenish-blue.	Blue-violet.	"	"
	Orange-red.	Yellow-orange.	Blue-green.	Blue-green.
	Green.	Green.	Crimson.	A less violet crimson.
S. Shepherd	Blue-violet.	Blue-violet.	Very pale yellow.	Yellow.
	Red.	Slightly orange-red.	Blue-green.	Blue.
Lumiere	Green.	Green.	Very pale pink.	Crimson.
	Blue-violet.	Blue violet	Pale yellow.	Yellow.
	Light orange.	Light orange.	Greenish blue.	"
	Light yellow-green.	Green.	Crimson.	"
Klein's for collodion emulsion.	Crimson.	Blue.	Yellow.	"

The colours recorded through the red filter are always more orange than the filter itself when using dry plates, because of the deeper red not photographing. In cases like Ives'

filters, where some green is transmitted by the blue filter, it is rarely recorded.

I have here a rather interesting filter. Its colour is red, but a spectrum positive made from a negative on a Lumière B plate shows the colours photographed to be crimson. The reason is that it transmits a little violet, barely enough for the eye to see, but enough to affect the photographic plate equally with the red. By placing the negative in the spectrum its complementary is seen to be green. Another red filter, one made with Scarlet R.R., shows no visual defect, but when photographically tested is found to transmit the ultra-violet.

Comparison of the Region Photographed with the Region Absorbed by the Printing Colour.—This can be effected by cutting the dyed films and the spectrum negatives into strips and placing a piece of negative and its printing colour side by side in the spectrum, and noting whether the light is stopped by each in the same manner. Taking Sanger Shepherd's filter first, we see that, whereas the whole of the blue and violet is stopped by the yellow dye, some of the blue is allowed to pass by the blue negative, which is the reason why we saw its complementary to be a pale yellow. This is one of those cases where the true printing complementary to the filter record would be quite impracticable for use. Both the green negative and the "minus green" dye, and the red negative and the blue-toned lantern plate match each other very closely in the region stopped, with the usual want of transparency to violet in the former. With all three of Lumière's filters and dyes, the region absorbed by the filter is considerably greater than that stopped by the negative.

A Scheme of Testing.—We will next consider how a fairly complete set of tests may be made, and for this purpose I will take a set of filters which I have used on plates orthochromatised with ethyl red. The filters were composed of the following dyes:—A methylene blue for the blue filter, naphthol green for the green, and a mixture of Biebrich scarlet and naphthol yellow for the red. The dyes used for staining the gelatine reliefs were brilliant yellow, erythrosin, and fast green (blue shade).

(A.) Hues of the Dyes and their Complementaries.—I have here the three negatives taken of this spectrum through the filters on a Castle plate which has been bathed with ethyl red. On placing these back in the spectrum and combining to a uniform patch of colour the light which they allow to pass, and comparing these colours in turn with the printing dyes, we see that the brilliant yellow matches exactly the colours not stopped by the blue negative, the erythrosin is redder than the colours passing the green negative, while the fast green does not quite match the complementary of the red record, being a trifle too green. (B.) Absorption Regions of Dyes and Regions Photographed.—On projecting an image of the spectrum and placing side by side in it, in pairs, the negatives and films stained with the printing dyes, you will notice that the brilliant yellow stops the blue and violet light in exactly the same manner as does the blue negative. The region of greatest absorption of the erythrosin corresponds to the region stopped by the green negative, but the blue and violet are somewhat damped. The fast green absorbs the yellow-green and the violet a trifle too much, and also transmits a trace of the extreme red. Now, although, as you see, the extreme red is not recorded in the red negative, it should not occur in its printing colour. (C.) The Blue-Violet of the Spectrum and its Reproduction.—The part of the Spectrum recorded only in the blue negative will be reproduced by the superposition of the erythrosin and fast green. If I now place the green negative in the spectrum, and cover up the red part, only the light of the region so recorded passes. This you observe is a fine blue-violet colour, while, by superposing the two dyes in the path of the white beam, this colour is seen to have

a purple tinge, due to the want of transparency of the erythrosin to violet and the slight transparency of the fast green to red. (D.) The Blue-Green of the Spectrum and its Reproduction.—I have here a transparency which has been made by exposing a lantern plate first under the green negative and then under the blue negative. The only part that then remains clear is where the plate was protected from the action of light by both negatives, i.e., where they overlapped. On placing this in the spectrum that particular region only is allowed to pass, and on comparing it with the fast green with which it would be rendered, a very close match is seen. (E.) The Green Region of the Spectrum and its Reproduction.—Provided that all the negatives overlap each other, which they do in the case we are considering, the part of the spectrum that is only recorded in the green negative can be picked out by exposing a plate firstly under a contact transparency made from the red negative, and then under one made from the blue negative. The part of the spectrum transmitted by this should match the colour produced by superposing the brilliant yellow and the fast green, which it does very closely. (F.) The Yellow Region of the Spectrum and its Reproduction.—This is picked out in an analogous manner to that used for the blue-green. Two successive exposures are given a plate under the red and green negatives. This, when developed and finished and placed in the spectrum, passes the overlapping region reproduced by the brilliant yellow. The match is seen to be fairly good, although the light from the spectrum is very dull, owing to the region being narrow. (G.) The Red Region of the Spectrum and its Reproduction.—This part is picked out by using the green negative and covering up the violet. The colour produced by placing the erythrosin and the brilliant yellow in the path of the white beam is a little less orange than the spectrum colour it is intended to imitate, which is rather an advantage. (H.) The Unrecorded Red.—By placing the red negative in the spectrum and covering up the green, blue, and violet parts, the deep red which was not photographed is seen on the screen.

A. J. BULL.

PREPARATION AND PROPERTIES OF PURE COLLOIDAL SILVER.

[The following translation from the "Bull. Soc. Chim." Series 3, vol. xxxi., No. 1, appeared in the "Chemical News" of May 6.]

In these new experiments I prepared colloidal silver according to Schneider's method ("Berichte," Vol. XXV., p. 1,281) by mixing 500 c.c. of a 10 per cent. solution of nitrate of silver, 500 c.c. of a 30 per cent. solution of ferrous sulphate, and 700 c.c. of a solution containing 280 grms. of crystallised citrate of soda. A reddish deposit is obtained, which is separated from its ferruginous mother-liquor, by means of a filter-pump, after having stood for half an hour. The precipitate is redissolved in a stream of distilled water, and the solution is treated with about twice its volume of alcohol at 95 deg. The addition of the alcohol causes a bluish-black deposit to be formed, precipitate of sol. The mixture is filtered through a Chamberland cylinder. The alcoholic solution of ferric citrate traverses the filter, and is collected in a recipient ad hoc; the precipitate of colloidal silver is deposited on the outside of the filter in the form of a pasty crust; after some time the filter no longer acts; it is then withdrawn from the liquid, but the aspiration is continued until the crust assumes an iridescent, brilliant metallic appearance, and seems to be dry. Then placing the filter in a glass containing distilled water the sol is allowed to redissolve.

I have observed that the Chamberland cylinder, the pores of which are obstructed by the colloidal molecules of silver, acts as a dialyser, and that on adding water and applying the vacuum we can cause the ferric salts and other impurities to

pass through into the interior, the sol of colloidal silver remaining in the outer solution. The solution may be again precipitated by alcohol at 95 deg., and again purified, as has just been described. If we have been careful to avoid the presence of all crystalloids, and especially of mineral acids, these operations can be repeated several times, and the colloidal silver retains its properties of a sol. Solutions of pure colloidal silver have no longer any tendency to become precipitated as a gel. Thus, while in the presence of the mother-liquid during its preparation the black insoluble gel. is produced in a few hours, solutions of colloidal silver free from electrolytes can be kept for several weeks without any change.

It is interesting, in practice, to notice the action of the alcohol; when we are obliged to leave the colloidal silver in very impure circumstances, it is sufficient to cause the precipitation of the sol by means of alcohol; the colloidal silver thus precipitated retains its properties of a colloid for a very long time, even in the presence of an excess of crystalloid salts, which under ordinary circumstances would rapidly transform the colloidal silver into the insoluble gel. By applying this method of purification, I have succeeded in obtaining, after a first purification, a solution of colloidal silver containing per 100 c.c.:—0.480 grm. of material dried at 100 deg., 0.478 grm. of material stable at a bright red heat, and 0.383 grm. of silver, that is 81.7 per cent. of silver; the difference was almost entirely iron. After two purifications, 100 c.c. of the solution contained 0.300 grm. of material dried at 100 deg., and 0.2897 grm. of silver, or 96.59 per cent. of silver. This pure solution of colloidal silver has all the properties of colloids, which have been published by my friend Posternak and myself, and which have been partly observed by others. The various electrolytes, dilute carbonate of soda, nitrate of potassium, perchloride of iron, sulphate of copper, etc., cause the precipitation of the gel.

If we evaporate the solution in vacuo, and dry the pasty mass collected on a Chamberland filter, metallic silver is formed. On the other hand, the aqueous solution of the sol is very stable. We can even keep this precipitated sol on porcelain in concentrated alcohol. Colloidal silver thus purified dissolves in alcohol, but only in the presence of water; it is insoluble in absolute alcohol. Purified colloidal silver dissolves easily in glycerin at 30 deg. We obtain organosols observed by Schneider, which will be the subject of a future paper. If we treat a solution of pure colloidal silver with another colloid, such as gum, gelatin, or a sodic solution of acid-albumose, we can obtain, by evaporating in the cold in vacuo, a solid mass in which the silver has preserved its physical colloidal state, and can be redissolved in distilled water. I shall return to this in a future paper on these preparations. The summary of all these facts makes us admit with Carey Lea (*"Zeit. Anorg. Chem.,"* Vol. XIV., p. 341) that all the preparations of colloidal silver contain the silver, not in a special allotropic form, but that the fine particles of silver, which were unable to become conglomerated at the moment of their production have remained in the free state in solution.

The transformation of the sol into the gel, and into metallic silver, takes place naturally every time the physical molecules are condensed or brought into contact one with the other, either under the influence of electrolytes, by precipitation, by crystallisable salts, or by reason of the loss of liquid support through dilution; by the evaporation of solutions of pure colloidal silver, or by simple mechanical action, as we have shown by grinding up colloidal silver. On the other hand, the colloidal form of silver is stable in pure solution in water, alcohol, or glycerin. In the presence of other colloids we can again conserve silver in the colloidal form, even in the solid state, as shown by Paal (*"Berichte,"* Vol. XXXV., p. 2,224), with lysalbinic acid.

A. CHASSEVANT.

THE PHOTOGRAPHING OF SPLASHES.

[A paper read before the Royal Photographic Society.]

THE branch of photography to which I draw your attention—that of photographing small objects in motion with the aid of the electric spark, is somewhat unusual, possibly on account of a certain element of danger attending the discharge of a large number of Leyden jars, and probably because of certain technical difficulties. The photographs I have taken are of one of our commonest phenomena—a splash—followed throughout its brief, but eventful history. Through a curious coincidence, these photographs (a series of which I showed at your exhibition last year) are deprived of their originality, as it appears that similar results have already been obtained by Professor Worthington, who published them in a magazine two or three years ago. His results, however, were produced by methods entirely distinct from those to which I refer in this paper. I shall have occasion to use the term "surface tension" whilst describing my slides, and it may be advisable to explain what is meant thereby. The nature of surface tension can be judged only by its effects, one of which is the manner in which every fluid, when unsupported, immediately assumes a globular shape. The only logical hypothesis which will explain this and other phenomena of surface tension, is the inference that, in some manner, the external surface of any fluid, whether molten steel or water, is possessed of a very high degree of elasticity. One may imagine the surface of a fluid to be coated with an elastic film, so thin that even a soap film must have its coating on either side, yet leaving a sandwich, so to speak, of ordinary water in between. Among other phenomena due to surface tension I may mention capillary attraction, the fact that the end of a column of mercury in a barometer is convex, that a needle can be floated on water, and the breaking of a jet of water into drops. This natural force is illustrated by the clinging together of the hairs of a large badger softener after immersion in water. There is no difference in the appearance of the brush, whether totally immersed or dry, but when withdrawn from the water, the surface tension of the water draws the hairs together, an effect that is not due to the weight of water held by the brush, as the force remains the same, whatever the position of the brush. The phenomenon of a splash is due to the same force which I believe is scientifically defined as "that force possessed by the external surface of all fluids which forces it, when unsupported, to assume the shape having the least area"—which is, of course, the sphere.

The first twenty slides are from photographs of the splash caused by a rough steel sphere falling into milk:—the formation of the "coronet," its alteration to a "crater," and later to a flat ring through surface tension. The emergent jet characteristic of this form of splash and its dissolution, and the formation of the concentric ripples are clearly shown. Then follow five slides dealing with the splash, or rather the absence of one, caused by a highly polished steel sphere falling from the same height, each picture of the series being separated by a timing interval of 1-1000th second. Next come two slides of the splash caused by a rough steel sphere falling from a height of 18 inches, showing the large crater formed, and its occasional change into a bubble. In the complete series, the photographs follow each other with the regularity of a cinematograph; each, however, being that of a separate and distinct splash. Repeated experiments prove that a splash is one of the most regular of natural phenomena, provided that each splash is produced under identical conditions, of which the most important is the height from which the object causing the splash is allowed to fall. This condition is easily fulfilled provided the same fall be retained in all cases; it may reasonably be assumed that the same sequence of events will occur during the splash, and this assumption is supported by the photographs. It only remains, therefore, to devise some means by which a spark is timed to occur at the instant at which the ball touches the fluid, the image of the ball being focussed and the room being in darkness. The negative, when developed, will show the ball in the position named. Then, timing the spark for, say, 1-200th second later than the former one, the next negative will show a stage of what is, virtually, the same splash, later than the first photograph by that amount of time. It is by the repetition of this process that I have obtained the photographs which I have shown. The timing is effected by a chronograph of peculiar construction. "Chronograph" is perhaps an unsuitable description, as the function of a chronograph is to record periods of time.

the instrument I employ is a refinement inasmuch as it determines time periods of time up to three seconds with great accuracy. It consists of a train of wheels actuated by a heavy weight. The axle of the wheels is continued outside the case containing the rest of the mechanism, and carries two drums, one of which is fixed to the axle, the other being free to revolve loosely, or by means of a nut, capable of being firmly clamped to the fixed drum so that the two may revolve as one. The fixed drum is divided on its periphery into 300 divisions, and as it revolves once in three seconds, it follows that each division corresponds to 1-100th second. The movable drum has a dial engraved on its surface by which the divisions on the fixed drum can be subdivided into tenths. In this way a reading to 1-1000th second, or any longer period up to three seconds is obtained. Placed vertically, at the zero line on each drum, is a metal stud, and on the plate of the machine are two weak brass springs, which, in their normal positions, rest on a brass bar, from which they are lifted at each revolution of the drum, thus breaking the electrical circuit. When the spring which is touched by the stud on the fixed drum is released, it is led to the apparatus which allows the ball to fall at the instant of the breaking of the circuit. From the spring actuated the vernier drum a second wire is led to and discharges a battery of twelve quart Leyden jars. The chronograph is set in motion with the drums adjusted to the calculated period, but until required it is put in circuit with the jars. The ball is then placed in the releasing apparatus and the high tension connection made. When the jars are charged, the circuit is completed, the ball is released, and spark made automatically; the result being a photograph of the ball in the predetermined position. I have stated that Professor Whithington obtained his results in a different manner, by means which appear to be scientifically more correct. In place of the somewhat complicated "chronograph" which I have described, he used his own chronograph—the attraction of gravitation. He employed two spheres, one to cause the splash and the other to discharge the jars. The "timing" sphere in the case of the first photograph, was allowed to fall from the same height as the "splash" sphere, passing in its fall between two electrodes in series with the Leyden jars and the spark gap. The two spheres were on the same electrical circuit and both commenced their fall at the same instant. The height from which the "splash" sphere fell was constant, while that of the "timing" sphere was adjustable, so that by increasing the height from which the "timing" sphere fell by a calculated amount for each photograph, a series of photographs was obtained free from the magnetic or clock errors to which my process is unfortunately liable, though they are eliminated as far as possible.

ARTHUR C. BANFIELD.

RECORD WORK AND LOCAL PHOTOGRAPHIC SOCIETIES.

[From the Handbook of the National Photographic Record Association.

The importance of record work is now being more generally recognised is shown by so many of the photographic societies having set up record sections, and the interest taken in the movement by librarians of our public libraries and curators of the museums, valuable local collections are now being formed. Many reports have been received, and, as a specimen of the work being done, the following extracts may prove interesting. The first photographic survey started was the survey of Warwickshire, which has been worked in a most systematic and thorough manner, and a collection of prints, now numbering thousands, has been made and deposited with the municipal authorities of Birmingham.

Brentford, Middlesex.—Up to the present there has not been any great effort to systematically work a photographic survey in this district, but Mr. F. A. Turner, librarian, Free Public Library, has tried what should prove a very useful collection, which ought to excite some enthusiasm in the local societies. The local album now contains some 200 photographs by Mr. Turner of buildings which have either disappeared or will soon do so, and in addition to these the section comprises a valuable collection of photographs of water-colour drawings of local interest and the reproduction of many of the old Middlesex maps and prints. And it is expected before the year is out that Mr. Turner will have made a complete series of pictures of the houses and shops in Brentford High Street, where some considerable alteration must take place. In addition

to his work at Brentford, to the Richmond Public Library he has contributed a collection of over 300 similar views.

The Photographic Survey of the Bristol District.—Mr. A. E. Hudd, F.S.A., hon. sec., is now at work in accordance with a scheme drawn up by the Clifton Antiquarian Club, and includes the City of Bristol and about 130 villages of Gloucestershire and Somerset in the neighbourhood.

Dundee and East of Scotland Photographic Association.—Survey section.—O. B. Hatch, hon. sec.—After an exhibition at Dundee of a collection of Sir J. Benjamin Stone's photographs, a survey was started, and the organisation would serve as a model for any society taking up similar work. There are two committees, one having undertaken to do the photographing, and the other, including Mr. MacLachlan, City librarian, Mr. A. H. Miller, F.S.A., literary editor of the "Dundee Advertiser," and other antiquarians, supplying all the antiquarian and literary information. The town is divided into three sections, and each section has a committee of workers. The negatives taken are sent in to a selection committee and those suitable are sent to a firm of printers, and three prints are made from each, one for the photographer, one for the town, and one for the association. The fund for carrying on the work is provided by the Town Council, who have made a grant of £50 a year for three years. Up to the present about 400 negatives have been selected.

The Ealing Photographic Society.—President, Mr. W. T. White. The survey of the Borough of Ealing was commenced in 1902. The six wards of the borough are allotted to various members, and a director appointed to organise the work in each ward. Persons who possessed old negatives, prints, documents, etc., were invited to lend them for copying, and up to date about 300 record views of Ealing have been secured, which will be deposited in the Free Public Library, Ealing.

County of Essex.—With regard to this county, Mr. Wire writes that a paper was read by Mr. Briscoe, Principal of the West Ham Technical School, at a meeting of the Essex Field Club, on a proposed organised survey of the county, and a start was made and a good deal has been done by individual photographers and a survey committee for the memorials of Greater London. Mr. C. R. Ashbee, chairman, has issued four monographs on the Trinity House in Mile End. The Church of St. Mary, Stratford; Bow; the Old Palace of Bromley-by-Bow, by Ernest Godman, and the fourth, just ready, of the Great House, Leyton; all these works being illustrated by photographs of the committee. Another committee, of which Mr. Wire is an active member, are at work on monographs of Stepney Church, Waltham Abbey Church, West Ham Church, East Ham Old Church, and Chelsea Parish. Colchester has been exhaustively done by a resident, and it is to be hoped the Corporation will secure this photographic collection. The Essex Archaeological Society have also published many pictures.

Herefordshire Photographic Society, record section (president, Mr. A. Watkins; C. Gethin, hon. secretary) have succeeded in collecting about 300 prints, which they have mounted in the same style as the National Record Association and deposited in the local museum at Hereford. The collection comprises the following subjects: St. Ethelbert Cathedral, Hereford; ruins of some of the Norman (Border) castles; ancient fonts; remains of several abbeys, etc., and a few old customs. The bulk of the work has been contributed by the president and hon. secretary.

Hull Photographic Society, survey section (Mr. J. W. Atkinson, hon. secretary) have photographed the district of Holderness, East Yorkshire, and have forwarded to the National Photographic Record Association an interesting collection of 63 prints of the churches of Patrington, Hedon, and Paull, Holderness.

Ipswich Scientific Society.—The photographic section of this society has been at work for some years, and a valuable collection of prints has now been deposited in the Reference Library under the charge of Mr. Frank Woolnough.

Survey of Leicestershire.—Major W. J. Freer, F.S.A., president; Mr. H. Alfred Roehling, M.I.C.E., hon. secretary. The survey was started in 1901, when two committees were formed, the archaeological and the photographic, and the following five Leicester and Leicestershire societies are represented:—The Literary and Philosophical Society; Architectural and Archaeological; Society of Architects; Footpath Association; and the Kyrle Society; with a view of making active search of all existing records, etc., and the drawing up of

a complete catalogue of all points of interest relating to archaeology, history, etc.

North Middlesex Photographic Society.—President, Mr. C. Beadle.—This society, established in 1885, holds its meetings at Hanley Hall, Sparsholt Road, Crouch End, London. In the early part of last year the council determined to start a photographic record section for the purpose of securing photographs of buildings or other objects of historical or archaeological interest in the northern part of the county of Middlesex now being so rapidly destroyed by the advancing growth of London. Up to the end of the year some 70 prints have been received, taken by the president, Mr. Marchant, Mr. Mummery, etc., including Salisbury House, in which the notorious Judge Jeffries resided, and of Bury Hall, both of Lower Edmonton, an old 14th century Tudor residence once occupied by Bradshaw, the regicide. At the annual exhibition of the society 33 prints were hung.

Oxford Camera Club (Sir W. J. Herschel, Bart., president) are supporting the committee formed for a complete photographic survey of the county.

The Rotherham Photographic Society have formed a record section, and have drawn up a scheme for a photographic survey, and have published a list of places to be included in the survey, but up to date not much progress has been made with the work.

Photographic Record, Shropshire.—The survey was commenced by Mr. F. R. Armytage, the late secretary of the record committee, and over 200 prints have now been deposited with the Borough Librarian at Shrewsbury, and it is the intention of the book committee to have them mounted in albums for public reference.

Somerset Archaeological Society have formed a photographic record committee, with Mr. C. H. Bothamley hon. secretary.

The Photographic Survey and Record of Surrey.—Right Hon. Viscount Midleton, president; Mr. H. D. Gower, hon. secretary.—This society was inaugurated 1902, and the collection now numbers about 700, and are arranged in six sections—architecture, art and literature, anthropological, geological, natural history, scenery and passing events, and is permanently housed at the Public Library, Croydon, under the charge of the hon. curator, Mr. J. S. Jast, chief librarian of the Croydon Public Library. The prints are mounted on individual mounts, and are stored in suitable boxes so as to allow any print to be located immediately.

The Woodford Photographic Society (Mr. F. G. Emler, president) have been doing some very useful photographic work in their district, and have collected some 200 prints, which are being bound up and will be deposited in the Public Library.

Other societies have been established at Wirral by the Birkenhead Photographic Association, Y.M.C.A. prints will be deposited in the Birkenhead Library, and by the Coatbridge Photographic Association, Mr. G. W. Campbell, hon. secretary.

Many other photographic societies are also engaged in record work of which no particulars have come to hand.

No. 8 of the "Practical Photographer" Library Series has reached us. This month the pictorial work of Frank M. Sutcliffe is dealt with in an able manner, while the greater part of the book is devoted to hand-camera work. Many useful articles, hints, tables, and scales are included.

In a recent issue we noticed the photographic work done by Prince Khilkoff, Minister of Ways and Communications of the Russian Government, and the use of the Kodak and Kodak Developing Machine in warfare, applied particularly to the crossing of Lake Baikal by the Russian troops. Kodak Limited draw our attention to an error which inadvertently crept in: the films were developed on the spot by Prince Khilkoff and were sent to the St. Petersburg branch of the firm to be printed from only.

A new price list is to hand from Thomas Illingworth and Co., Ltd., Willesden Junction, N.W. Enlargements, photographic printing, carbon tissues, mounts, and special frames for photographs are some of the firm's specialities. We understand that the firm has lately greatly improved and increased its plant, and no pains will be spared in future to ensure prompt and punctual delivery. Special discounts are offered to professional photographers and dealers. A postcard to the above address will bring full particulars.

WHERE THE HOUGHTON CAMERAS ARE MADE.

THE average man who handles a camera, although perhaps admiring its finish and the accuracy with which it is made, seldom gives thought as to how or where it came into being. We are all, nowadays, too ready to take things for granted, and do not trouble ourselves much about what is not immediately under our notice. Suffice it is that the article is there and that we possess it, and that it answers the purpose for which we bought it. The making of a camera, instance, is far more complicated, and requires a far greater number of separate and distinct operations, than one would ever imagine, if it were not for the perfection of modern machinery, the construction of a camera, like the "Sanderson," for instance, would cost so much that it could not be sold for less than five times its present price. Practically all our cameras (says "Houghtons' Monthly"), and a great number of the other articles that we sell, are made at works at Hackney, and as many of our dealer friends will not do so, we are interested in the manufacturing side of the goods that they handle, we purpose giving a short description of the work that goes on at the Spratt Bros. branch of Houghtons, Limited. When one enters the whirling mass of machinery amidst which four hundred employees are all busily engaged making camera fittings, and the thousand and one articles connected with the photographic and optical trades, it is difficult to imagine that twenty years ago this vast business was such a small concern, and that the engineering plant consisted of a "two-man power" engine and a single circular saw. Yet that was all that was when the three Messrs. Spratt entered the business, succeeded by their father, who was a well-known instrument case maker in the early days of the Victorian Era.

It is significant to see how business enterprise and forethoughtful men who have realised to the fullest degree the possibilities of mechanical tools have created a business of this magnitude. In the 'forties and 'fifties of the last century, the work was confined to the making of surveying and drawing instrument cases, and the work, of course, was entirely done by manual labour. Now there seems to be a machine or series of machines to do everything. The requirements of the work demand perfection, and if a machine cannot be purchased to do what is required it has to be built on the premises. There are, in fact, more than a dozen machines now running at the Tudor Works that were designed and executed by the mechanicians employed by Messrs. Spratt Bros., and it is largely owing to these fascinating and almost human pieces of machinery that beautifully constructed perfect instruments can be produced at a price that would have been impossible a decade back.

Looking down into the stokehold of the boiler house and watching the stokers bank up the furnaces of the great boilers, one almost imagines that one is on board an ocean liner instead of at a factory, and as the red glow lights up the faces of the half-naked stokers, one cannot help feeling how little the busy scene suggests the photographer's camera and its eminently peaceful surroundings after it has left the works where it had its genesis. Then commences a tour of the various shops. The noisy metal rooms where the tools are made, the brass turning and stamping rooms where curiously fashioned and fascinating machines shape from the solid brass the fittings that form such a prominent feature on our cameras. Machines that are turning out lens mounts and tripod heads and cutting through the soft metal as if it were soap; machines that are stamping out the ends of film spools, the hinges of dark slides, the points of tripods, the struts, bushes, finder covers, and endless other fittings often, in the crude state difficult to identify, whirling, twisting, humming, and throbbing in every direction. Not a machine idle, all going at full speed, for the pressure of work is heavy, and every man in the building seems alive to the part that he and the machine he is responsible for has in the great undertaking.

Then we pass into the cabinet-making shops, where thirty or forty circular saws buzz and sing through their work. The fine grain of wood produces a very different note from that heard when a coal-cut saw is coughing and spitting its way through a rough plank in a builder's yard or a sawmill. Here all the wood employed is of the finest, and the song of the saw is sung in a richer, fuller note. Here one sees the camera in the making. The cases are piled high, yet only the ghosts of what they will be, but solid, substantial shapes for all that, and made so perfectly, joined so faultlessly, that it seems

ity to cover them with leather and hide the beauty of their workmanship. Ascending to the upper floors we find many other operations in progress. Here is a room where forty or fifty girls are French-fitting cameras, dark slides, and instrument cases. Another room contains a young army of men putting cameras together, screwing and taping and piecing all the fragments into one complete instrument. Another room is full of girls lacquering brasswork, another full of workers gluing on leather. Here there are men making iris diaphragms. There are others putting together tripod legs. Every spare inch of space is occupied; everyone busy, everyone with his hands full of work, from the smallest machine boy to the foreman, and everyone useful. Surely, a model factory and a model staff.

Although there are from 25,000 to 30,000 cameras made at the Tudor Works every year, the Messrs. Spratt Bros. in no way confine themselves to camera making, for they still make articles for use by surgeons, astronomers, opticians, and architects, and in this capacity they have large Government contracts for the War Office and Admiralty. Much of this work is of extreme importance, and the precision construction necessary has been excellent schooling for camera-making. Scarcely a month goes by without a new labour-saving machine being added, and the Tudor Works have for years past been the largest, finest, and best equipped photographic apparatus manufactory in the kingdom.

The three brothers, Alfred, Henry, and George Spratt, all take an active part in the management of this department of Houghtons Limited. As Mr. Alfred Spratt said at the inaugural dinner the other day, it is "by their works ye shall know them." No better and more fitting monument to their energy and acumen exists. They have identified themselves with their "works," and well may they be proud of them.

New Book.

Bibliothèque Photographique: Le Téléobjectif et la Téléphotographie." By Thomas R. Dallmeyer. Traduction Française augmentée d'un appendice bibliographique, par L.-P. Clerc. Published by Gauthier-Villars, Quai des Grands Augustins, 55, Paris.

It is very gratifying to see that Mr. T. R. Dallmeyer's work on telephotography commands so much interest that a French version has recently been published. The popularity of the book in this country makes any reference to the text of Mr. Dallmeyer's work superfluous, but we desire specially to bring under the notice of our readers the valuable addition which has been made to it by the translator, M. L.-P. Clerc. This is a résumé of the principal dissertations upon the subject which have been published since 1834, when Peter Barlow and G. Dolland brought under the notice of the Royal Society the value of an achromatic concave lens for increasing the magnification of a telescope. The fact to which Dr. M. von Rohr draws attention in his work on the "History and Theory of the Telephoto lens," that Porro was the first to construct such an instrument, receives confirmation by an abstract of the notice in the "Comptes Rendus de l'Académie des Sciences, 1851," Vol. XXXIII., pp. 128 and 91, concerning the photographs of the eclipse of the sun taken in 1851. A further abstract from the "Bulletin de la Société Française de Photographie," makes it apparent that Porro obtained his idea of the construction of a telephoto lens from Professor Petzval's orthoscope. Much interesting and valuable information concerning telephotography may be found in these bibliographical summaries made by M. Clerc, and we recommend the volume to all who use the telephoto lens.

We have received from Messrs. Dawbarn and Ward, Ltd., 6, Harrington Avenue, London, E.C., a copy of their latest list of publications. It forms an alphabetical subject-title index to a most comprehensive series of handbooks and guides for the photographer, the model engineer, the artist, the amateur craftsman, the electrician, etc. A copy will be sent to any of our readers on application.

THE ILFORD COMPETITIONS.

The following particulars of the Ilford £750 competitions are given in the May number of "Photographic Scraps":—Professional and amateur photographers at home and abroad are cordially invited to take part in this competition. The classes are so arranged that professionals do not compete with amateurs. The name and address of a successful competitor will not be published except at the request of the competitor concerned. Competitors in the Colonies and in foreign countries can, if they prefer to do so, hand their prints ready packed to their dealers, who will arrange to send them on to Ilford at the ordinary rates. Secretaries of photographic societies can obtain extra copies of the conditions, post free, by applying to Ilford, Limited, Ilford, London, E., stating the number of copies required. It will be noticed that the prizes are offered for prints on Ilford papers, or lantern-slides from negatives on Ilford plates. By this means competitors are saved the trouble and expense that would be involved in forwarding their negatives from all parts of the world. In making the awards, however, attention will be paid throughout to the qualities of the negatives as well as to the merits of the prints themselves, and, if it should appear desirable, competitors will be asked to send on any particular negatives for examination. Such negatives should be carefully packed, first in a card-board box, well padded, and then in a wooden case, and be insured against all risks. Restrictions of all kinds have been avoided in order to leave photographers unfettered, both in their choice of subject and their treatment of it.

OPEN TO THE WORLD.

CLASS P. PROFESSIONAL. For Professional Photographers

Prints from negatives on Ilford plates or flat films, any size or subject.

First prize	£35 0 0	£35 0 0
Second prize	25 0 0	25 0 0
Two prizes of	15 0 0	30 0 0
Four prizes of	10 0 0	40 0 0
Eight prizes of	5 0 0	40 0 0
One hundred prizes of	2 2 0	210 0 0

116 prizes £380 0 0

CLASS A. AMATEUR. For Amateur Photographers.

Prints from negatives on Ilford plates or flat films, any size or subject.

First prize	£35 0 0	£35 0 0
Second prize	25 0 0	25 0 0
Four prizes of	10 0 0	40 0 0
Five prizes of	5 0 0	25 0 0
Twenty-five prizes of	2 2 0	52 10 0
One hundred prizes of	1 1 0	105 0 0

136 prizes £282 10 0

CLASS JA. JUNIOR AMATEUR. For Amateur photographers under eighteen years of age.

Prints from negatives on Ilford plates or flat films, any size or subject.

Two prizes of	£5 5 0	£10 10 0
Four prizes of	2 2 0	8 8 0
Twelve prizes of	1 1 0	12 12 0
One hundred and twelve prizes of	10 0	56 0 0

130 prizes £87 10 0

The Photochrome Company, Ltd., 35 and 36, Hosier Lane, Snow Hill, E.C., have sent us some specimens of their latest productions in coloured postcards. They say: "It is a matter for regret that in some cases a great quantity of inartistic work of poor execution has been dumped on the market, with the natural tendency to bring contempt on an otherwise interesting and artistic hobby. The knowledge of these facts has encouraged us to the production of a series of coloured postcards on a scale never before attempted." The cards are very excellent examples of colour printing, and appear to be produced by the same methods and process used in the well-known photochrom pictures adopted by the railway companies, etc.

AMERICAN PROFESSIONAL PORTRAITURE AT THE KODAK GALLERY.

THE Kodak Company have on view this week at their principal London branch, No. 43, Clerkenwell Road, E.C., a collection of photographs which should prove of interest to our professional readers, who will be afforded every opportunity of personally inspecting and examining the prints. The exhibition consists of a number of large direct portraits produced by Stein, Falk, and many other prominent studio workers in the principal American cities. To the best of our recollection no representative collection of Transatlantic portrait work has hitherto been shown in this country, although we ourselves at the Great Paris Exhibition a few years ago saw many examples of it. Readers of the more "advanced" periodical photographic literature of the United States, England, and the Continent are by this time tolerably familiar with the work of those ambitious pictorial portraitists whose avowed endeavour it is to eliminate from their prints all traces of their photographic origin. The consistent manner in which this "sort of" photography, to borrow Lord Halsbury's famous expression, is passed off may give rise to the idea that there exists amongst the public an appreciable demand for such "freaks," as our American confreres contemptuously, if not quite accurately, describe them. For "freaks," as we understand them, are spontaneous productions, whereas photographs of the ultra-pictorial or impressionistic kind—the terms are used for purposes of illustrative convenience—trace their origin to a strenuous energy of effort, which is perhaps both futile and misapplied, and so might be devoted to other and more profitable ends. It is still the "usual thing" of the good and pronouncedly photographic kind which pleases—"all the world" (or most of it) and his wife—oh, yes, especially Son Altesse.

The dominant characteristics of American professional portraiture of the kind submitted to our inspection this week may be succinctly described as combining well concentrated effects of lighting with ease, freedom, and dignity of pose, the print registering every nuance of a well-graded negative. You are conscious in looking at these prints that they are the outcome of a thorough mastery of technique; so many object lessons, in fact, of non-mystical lighting, posing, developing, and printing. As such the collection is well worth studying by our professional readers, who may wish to know what is in request by the profitable clientèles which, we understand, abound in the States.

A feature of this very fine display is that the prints are made on Aristo collodio-chloride, a process in great popularity with American professional workers, the tone being obtained by gold and platinum, a beautifully effective depth, richness and delicacy of effect so resulting. We understand that "Aristo" will be brought more prominently under the notice of British photographers. From the same source also comes the Aristo self-toning (collodio-chloride) paper, which yields results quite comparable in appearance to the best class of albumen prints. Of these papers we shall, no doubt, have future opportunities of writing from practical trial. Our present purpose is to draw the attention of our "bread and butter" readers to a notable show of American portrait work, a study of which should on no account be missed.

WILL "Q. W. L.," who wished to know the value of portrait lens made by Harrison, New York, and to whom we replied in last week's "Answers to Correspondents," kindly communicate with W. Kent, 27, Upperton Gardens, Eastbourne.

WE have received a copy of "The Lecture Agency Date Book" from the Lecture Agency, Ltd., the Outer Temple, Strand, W.C. This "Date Book" has been specially compiled for the use of ministers, lecturers, public speakers, musicians, entertainers, secretaries of societies, and others who are compelled to make engagements a long time in advance, and before the ordinary diaries for the following year are available. It contains space for every day to June 1906, and a table up to December 1910, showing on what date Easter and the other Feast Days and Holidays fall, together with various other items of useful information. The "Date Book" includes an insurance policy of £100 in case of death by railway accident for the twelve months ending June 30, 1905.

Patent News.

The following applications for patents were made between April and April 30, 1904:—

- Borders.—No. 9,515. "Improved means for printing borders on photographs." Percy Archibald Hillhouse.
 Changing Boxes.—No. 9,720. "Improvements in or relating to photographic changing boxes or apparatus for changing flat sensitive surfaces arranged as a pack." Arthur Lewis Adams.
 Sheaths, etc.—No. 9,725. "Improvements in and relating to sheaths or wrappers for packing, exposing, and developing photographic plates or films." Arthur Reiner.
 Cameras.—No. 9,902. "An improved appliance for use with photographic cameras." Arthur Hubbard.

FORTHCOMING EXHIBITIONS.

- May 16-28.—Photographic Society of Ireland. Hon. Secretary, E. Webb-Smith, care of Royal Dublin Society, Kildare Street, Dublin.
 May 24-28.—Devonport Camera Club. Hon. Secretary, A. Catford, 78, Charlotte Street, Devonport.
 June-October.—Glasgow Photographic Exhibition. Secretary, Gallery and Museum, Kelvingrove, Glasgow.
 July 14 to September 30.—Vienna Photographic Society. Secretary, W. Burger, Karmelitergasse 7, Vienna 11.
 August 1.—Andover and District Horticultural Society. Photographic Section. Hon. Secretary, W. L. Gradidge, Jubilee Hall, Andover.
 November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.
 November 23-26.—Hove Camera Club. Hon. Secretary, S. Sargeant, 55, The Drive, Hove.
 December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.
 December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102 West 101st Street, New York.
 December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.
 December 13-20.—Southampton Camera Club. Hon. Secretary, S. Kimber, Oakdene, Highfield, Southampton.

FORTHCOMING COMPETITIONS.

- May 31.—Ensign-Vidil. £100 in prizes for negatives on Ensign-Vidil films. Houghtons, Limited, 88-89, High Holborn, London, W.C.
 June 30.—"Photographic News" Quarterly. Money prizes, silver and bronze medals for prints. Any subject. "Photographic News," 9, Cecil Court, Charing Cross Road, London, W.C.
 June 30.—Kodak. £1,000 in cash prizes for pictures taken on Kodak films and plates, etc. Kodak, Limited, 41-43, Clerkenwell Road, London, E.C.
 October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.
 October 31.—Coxin. 68 prizes for users of Coxin. Judging two pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.
 December 31.—Barnet. Nineteen classes. Prizes valued at £100 for lantern slides and prints made with Barnet products. Elphinstone and Sons, Limited, Barnet, Herts.
 Ilford. £750 in prizes for negatives on Ilford plates. Ilford, Limited, Ilford, E.
 Luna paper. £240 cash prizes for prints on Luna paper. Lucien Allegre and Co., 59a, New Oxford Street, London, W.C.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
.....	Everton Camera Club	Half-day Outing.
.....	Camera Club.....	<i>Fearful Monsters.</i> Mr. S. C. Kaines Smith, M.A.
to 11	Kodak Exhibition.....	Masonic Hall, Birmingham.
.....	South London Photo Society	<i>A Simple Means of Controlling Gradation in Bromide Prints and Lantern Slides.</i> Demonstrated. Mr. John Sterry.
.....	Bowes Pk. and District Ph. Soc.	Competition. Outing Prints.
.....	The Optical Society	<i>Standardisation of Spectacles and Eyeglasses.</i>
.....	Birmingham Photo. Society.....	<i>Gum Bichromate Process.</i> Demonstrated. Mr. J. Page Croft.
.....	Bialgowrie and Dis. Ph. Assoc.	<i>Pinhole Photography.</i> Mr. James Richardson.
.....	Croydon Nat. His. and Sc. Soc.	<i>The Croydon Bourne.</i> Mr. Baldwin Latham, M.L.C.E.
.....	Nelson Photographic Society	Demonstration. Mr. F. Whitaker.
.....	North Middlesex Photo. Soc.	<i>Printing and Toning P.O.P.</i> Mr. S. H. Bentley.
.....	Everton Camera Club	<i>A Simple Developer.</i> Demonstration. Mr. E. C. Alcock.
.....	Watford Camera Club	Competition—"Producing the Best Picture from an Exposed but Underdeveloped Plate."
.....	Camera Club	<i>Domestic Life in India.</i> Mr. J. D. Reek, C.I.E.
.....	London and Prov. Photo. Asso.	Open Night.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

MAY 2.—A special meeting of the General Committee was held to arbitrate a case remitted to the Committee of the Association for decision by His Honour Judge Russell of the Reading County Court, involving the reasonableness of a charge made by a photographer for photographs supplied. Present: Messrs. Alfred Ellis, F. A. ridge, Wm. Grove, S. H. Fry, H. E. Hull, Martin Jacolette, A. Jackie, H. S. Mendelssohn, Edgar Scamell, Ralph W. Robinson, and Lang Sims. Mr. Alfred Ellis, President, in the chair.

After careful consideration and examination of the photographs, decision was agreed to, but as the case is sub judice until the decision is confirmed by the judge, the particulars cannot be published.

A letter from Mr. Wm. Crooke, of Edinburgh, was read, consenting to allow his collection of portraits now on exhibition at the Royal Photographic Society, to pass to the Exhibition of Professional Photography to be held at Derby in the summer, and a similar letter from Mr. Frederick Hollyer.

Letters were read from two members thanking the Committee for valuable advice in cases of difficulty.

CAMERA CLUB.

MONDAY, MAY 2, was an open night at the club, which means that there was no formal lecturer, but that members were invited to bring forward any matter of interest, or to call attention to any novelty. and it is a noticeable thing that very often upon these off nights an interesting discussion is apt to arise out of some insignificant matter. Mr. Godfrey generally occupies the chair on these occasions, but he had to keep indoors by the doctor's orders, and Mr. T. C. Hepworth took his place.

Mr. Routledge showed a few slides which he had lately taken in British East Africa, where he has been the spectator of some of those minor skirmishes which take place between different tribes of natives, and which are of such constant occurrence that they do not often get reported as far as London. He spoke of the Masai as being splendid soldiers, and "the lancers of African warfare." They are well behaved, and there is among them a system of military discipline which is invaluable. Send them on an expedition to strike terror into a neighbouring tribe which has been giving trouble, and they will do the business effectually. "There is no need for an ambulance," said Mr. Routledge, significantly. Some pictures of the scenery of this part of the world were also shown and explained by their owner.

Mr. Gordon showed an interesting positive transparency of the interior of a church, because it touched upon a subject in which he

was much interested, and about which he read a paper at the club some weeks ago. The picture was produced by mingling a positive with a negative image, and the device had been so successful in this instance that all halation was done away with, while, at the same time, exquisite detail was shown in the very darkest parts of the picture. Mr. Gordon pointed out that the meaning of halation was a dense high light, which cannot be printed out sufficiently without loss of detail in the other parts of the composition, but that if the thin parts of the negative are masked with a weak positive image, a lengthened exposure can then be given without disastrous results. This particular picture has been in Mr. Hepworth's possession for about twenty years, and, if he remembered rightly, the process had been patented at the time.

The next matter dealt with was the question of the best way of fitting up a dark-room, the subject having been brought up in the form of a question. This gave rise to a discussion which was interesting, as it elicited from those present a description of the many little dodges they had adopted in the way of lighting, and arranging other details of their dark-rooms.

A number of lantern slides belonging to the club, which had not seen the light for some years, were then shown, and the Chairman suggested that as most of them bore no titles, any member who recognised a picture to which, within his knowledge, any particular interest attached, should make some observations upon it. The opportunity came when a picture of the Forum at Rome was projected upon the lantern screen; a picture which was taken about ten years ago. Mr. Casson, who had visited Rome within the past month, and who had evidently made a careful study of the excavations in progress there, pointed out that many of the houses shown in the picture had been cleared away, and that valuable archaeological finds had been made on the sites which they occupied. Perhaps the most interesting of these was the discovery of the concrete platform upon which a statue of Domitian formerly stood. Signor Boni, under whose direction the excavations are being carried on, was strongly impressed with the idea that in this mass of concrete some relics might be found, for it has always been customary—and is in our own time—to associate with a foundation-stone coins, etc., giving some key to the date of the event. After chipping away much of the hard concrete a hollow chamber was found covered with a slab of stone, and within the recess were found five very beautiful vases, one containing a nugget of pure gold, and the others the remains of wine, food, etc., which now await analysis. The date of this interesting relic is supposed to be A.D. 84, but the vases, from their peculiar pattern, are believed to date from some four centuries earlier. Here the archaeologists have somewhat of a puzzle to solve. After a brief vote of thanks to those who had spoken during the evening, the proceedings came to a close.

On the following Thursday, Mr. David Christie Murray gave a discourse entitled, "Peace and War." He spoke entirely without notes, and gave a most interesting account of some of the incidents of a most strenuous life as journalist, as a member of the Press gallery in the House of Commons, and as war correspondent for the "Times" and other newspapers. He is the prince of story-tellers, and invests every incident with sometimes pathos, and sometimes rollicking humour, together with a dramatic force which is most attractive. He had nothing whatever to say about photography, and so we are not able to devote more space to the notice of a meeting which was most entertaining and enjoyable to those who had the privilege of being present.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MEETING held May 5, Mr. D. W. Hart in the chair.—Mr. Teape exhibited some test strips (negatives) to show that the Howard Farmer's reducer did not act on the lights more than the shadows. A portrait negative cut in two, one half of which had been chlorised, washed, redeveloped, and fixed, then submitted to the action of the Howard Farmer's reducer, did show a decided visual reduction, but P.O.P. prints made from the two halves were almost identical.

The members adjourned to 27 and 28, Fetter Lane to see a demonstration of the Adhesive Dry Mounting Co.'s process of mounting photographs, and a very pleasant and instructive evening was spent under the guidance of Mr. Garrett, the company's representative. Prints in carbon, platinum, silver (matt and glacé), supplied by members, were mounted upon paper and upon ordinary substance mounts,

with a facility and success quite surprising, a special adhesive, like a sheet of tissue paper, being the medium, this, under the print, being placed on the mount and subjected to momentary pressure under a hot press, and the mounting was completed.

A very ingenious gridiron straight-edge was shown for trimming the margins of prints, and was much admired. Various sizes of machines (or presses) were shown in operation, from cabinet to 30 by 24, and for amateur use Mr. Garrett showed what could be done by means of a gas-heated laundry iron. The advantages claimed for the process are that whatever the surface of the print before mounting, the same is preserved afterwards; that a photograph can be mounted with equal facility upon thin paper or upon thick board; that if the machine is not large enough to mount the print at one pressure, two, three, or more pressures can be given without any markings showing on the print.

At the conclusion of the demonstration, Mr. Drage voiced the sentiments of the members by expressing his satisfaction with everything that had been shown, and hoped that the company would meet with commercial success.

Members and friends are reminded that the summer outing will be to St. Paul's Cray Common, Chislehurst, on June 25, leaving Cannon Street about 2.30. Supper at the Bickley Hotel, close to Chislehurst Station, at 7.30. Tickets, inclusive of railway fare and supper, 3s. 6d. Reserved railway carriage both out and home will be provided. Fuller particulars later on.

CROYDON CAMERA CLUB.

WEDNESDAY, MAY 4.—An exposition by Mr. E. W. Taylor, showing how a negative might be "faked" was given, and illustrated by lantern slides of prints from negatives before and after treatment, which in most cases was a drastic one. With such apparently innocent aids as retouching pencil, knife, water colours, methylated spirit, cotton-wool, wash leather, matt varnish, pencil dust, and stump, and a suitable desk, the lecturer demolished houses—not necessarily jerry-built ones—or lopped off chimneys, or turned a desirable suburban residence into a dilapidated farmhouse with the greatest ease. Winding paths were introduced where pictorial composition indicated winding paths ought to be, and undesirable figures were obliterated, and merged into the surrounding landscape. One instance, in particular, attracted especial attention, inasmuch as a print was exhibited at the club's recent exhibition. The untouched negative, and resulting print, showed a cart laden with coal sacks leading up a lane, at the end of which, forming the horizon line, was a somewhat ugly mound of earth. The revised edition showed the same cart full of straw, and the mound transformed into a pretty rustic cottage, with an indication of distance, so to speak, thrown in. All the foregoing improvements, or alterations, were effected on the negative, and, if hardly desirable for purely record work, still, in many cases, and notably the last-mentioned, the means perhaps justified the end. With the assistance of P.O.P. double printing, masking, hand work on the print, and additions made by gumming on portions of prints from the same or other negatives, and finally photographing the doctored print, Mr. Taylor showed, as might be expected, still greater transpositions and alterations might be obtained. Amongst the many practical points discussed, the lecturer laid emphasis on "going slow" when reducing with spirit; patience, rather than elbow grease, was required. He used the knife chiefly for toning down small opaque spots. It should have a thin blade, razor edge, and be manipulated at right angles to the film. As a reflector, white blotting paper was satisfactory. When making additions to a print by gumming on, say a cut-out figure, then the edges of the piece of P.O.P. representing the figure should be reduced at the back to extreme thinness by sand paper. This preventing the junction showing.

In the animated discussion which followed, Mr. Dunmore complimented the lecturer on what he regarded as a wonderful display of legerdemain, he very much doubted if it was "photography." Another member said what he had heard that night reminded him of many years ago when he was giving a lantern lecture through France. The slides illustrated English towns and scenery. The lecture unfortunately fell flat, but directly the same slides were shown to illustrate Jules Verne's "Round the World in Eighty Days," things brightened up, no one was the whitest, and everybody was pleased. At the instance of the President, Mr. S. H. Wratten, a vote of thanks was accorded Mr. Taylor.

News and Notes.

At the meeting of the Royal Microscopical Society on April 10, a large tank microscope, made by Thomas Ross, presented to the Society by the Committee of the Quekett Microscopical Club, was exhibited. It was made not later than the year 1870, and designed for the purpose of examining objects contained in aqueous fluids. It was a beautifully-made and highly-finished instrument, and admitted of nearly every conceivable adjustment.

A new edition (the sixth) of "Practical Enlarging," by John H. Hodges, has just been issued by Messrs. Hiffe and Sons, Ltd. It is a very reliable little handbook, which should prove very popular with users of small cameras. The whole course of enlarging processes has very carefully gone into by Mr. Hodges. Working diagrams are given, and the book is well got up. It forms No. 6 of the "Photographic Book-shelf" series.

We have received specimens of pictorial postcards published by the Ozograph Company, Ltd., of 145, St. Michael's Hill, Bristol. They are excellent examples of half-tone printing, and we understand the firm has spared no expense in fitting up their factory to meet the exigencies of the ever-varying English climate, which so materially affects the different processes in collotype printing. In the matter of prompt delivery, price, and general finish the firm should be able to compete successfully with Continental productions.

MR. SRS. GOLD, SMITH, AND CO., of 4, Victoria Bridge, Manchester, send us a specimen of a new line they have just put out on the market. It takes the form of a neat little "albumette," founded on the principle of the well-known "Slip-in" albums with various shaped openings, and is intended to hold stamp-sized prints. These little albums are supplied in two sizes. One holds forty-eight stamp-sized photographs, the other twenty-four of the larger-sized stamps. They are very cheap, and should prove a popular line at seaside resorts for views and portraits.

DEATH of an Eminent Chemist.—Professor A. W. Williams, F.R.S., the eminent chemist, died on May 6, at his residence, 10, Grosvenor Road, Haslemere. The deceased, who was Emeritus Professor of Chemistry at University College, London, attained his eightieth birthday recently. He had been in ill-health for the past two or three years. He received his education in England, France, and Germany, being appointed professor of practical chemistry at University College in 1849, and professor of chemistry in addition in 1855, retiring in 1870. He was the author of several publications. He leaves a widow, a daughter of Professor T. Hewitt Key, one son, and one daughter.

UNNECESSARY ARTISTS.—The struggle for existence among artists was eloquently described on Saturday evening last by Sir John Lubbock, P.R.A., who presided at the annual dinner of the Art General Benevolent Fund, which was held at the Hotel Metropole. He stated that of late the number of artists who competed for patronage had greatly increased, and now they could be counted by the sands. This all added to the struggle for existence, and he made a strong appeal on behalf of those who helped to make beautiful homes of many of those present. Are we to regard this pronouncement as encouraging to the photographer with artistic aspirations, or as a warning?

FEDERATION of Photographic Societies of Northumberland and Durham.—The annual meeting of delegates of this Federation was held at Newcastle-on-Tyne on Wednesday evening, May 4, Mr. A. Cowling in the chair. The arrangements for the annual field day at Bishop Auckland, on Whit-Monday, were completed. It was decided to accept Messrs. Elkington's quotation for supplying bronze plaques for the design for which is being executed by W. R. J. S. Bertram, Mr. Thomson, of Darlington, was elected business manager for the Federation Record in place of Mr. Dent, who resigns. The Treasurer reported that the finances of the Federation were in a satisfactory condition. The following gentlemen were elected as officers of the Federation for the ensuing year:—Chairman, Mr. A. E. Cowling; South Shields Photographic Society; Hon. Secretary, Mr. A. Payne; Blaydon and Gateshead Camera Clubs; Assistant-Secretary, Mr. A. H. Wilson, Gateshead Camera Club. Secretary's address, Arthur Payne, 6, Tyne Vale Terrace, Bensham, Gateshead.

the "Evening News" is responsible for the following:—"Queen Alexandra will not have been at fault if the photographs which she took at Lismore Castle do not prove good ones. Her Majesty is as good a photographer as will be found among amateurs. Not only does she possess the art of developing; she has that more rare gift—eye for an effective landscape. One of her pictures was attended with remarkable results. It was the means of averting a tragedy, for a negative had been developed of a view she had taken of a train passing over the bridge at Wolferton, it was noticed that there appeared to be a curve in one of the uprights of the bridge. It there should be any mistake, that the film had been disturbed or ordered, her Majesty went again and rephotographed the bridge. In the second picture the result was similar. There was an undoubted weakness in the bridge, albeit it was not apparent to the eye upon casual observation. The King was consulted, and caused an examination of the bridge to be made by an expert, with the result that the picture was found to be in a dangerous condition of insecurity. Thanks to her Majesty's care and attention to minute detail, the flaw, having been discovered, was remedied. Wolferton Bridge has been built."

The Chemists' Exhibition.—A chemists' exhibition, organised by proprietors of the "British and Colonial Druggist," was opened Monday at the National Skating Palace, Argyll Street, W. Similar exhibitions have been held annually for the past ten years, and from the commencement have attracted considerable interest among chemists throughout the country and the Colonies. The present exhibition is larger than any of those which have preceded it, the exhibits, which are arranged in the area and on the first and second tiers of the building, comprise many novelties in pharmaceutical preparations, hygienic and sanitary products, dietetic specialties, and, in fact, the whole range of articles of interest to pharmacists, manufacturing and scientific chemists, physicians, surgeons, and photographers. One of the most interesting sections, from the point of view of the general public, is that devoted to photography. It contains many more exhibits than usual, including competition photographs, exhibitors' photographs, and the displays of representative houses for cameras, lanterns, plates, papers, chemical accessories, and the like. That the chemists' trade is not confined to drugs is shown by the large number of miscellaneous exhibits, which include mineral waters, opticians' goods, and fancy soaps and perfumery, the latter being particularly prominent. Among the scientific novelties shown are radium, helium, krypton, and argon. An exhibit by Messrs. Johnson and Sons, Ltd., of London, of crystallised chloride of calcium, containing 620 oz. of the pure metal, and valued at £1,395, attracted special attention. The exhibition, which contains 125 exhibits, will remain open until Friday night.

Burglars Captured.—At the Marlborough Street Police-court, on May 7, George Esser, porter, 31, of Queen Street, Seven Dials, and John Smith, 33, porter, with no home, were charged on remand with breaking into the shop, No. 54, Haymarket, and stealing sixteen gold and silver compasses worth £30, the property of Messrs. Sinclair & Co., opticians. They were also charged with being in possession of housebreaking implements. Henry C. Paty, an assistant in the employment of Messrs. Sinclair, deposed that on April 30, when he got to the shop, he found that the window had been broken and that a plush stand containing gold and silver compass charms of value of about £40 had been stolen. The property had been recovered by the police, who were at the shop when he arrived there. William King, a "street flusher," of Seymour Street, Camden Town, said that shortly before six o'clock on the morning of April 30 he saw the prisoners standing in the Haymarket. Smith had the compasses produced sticking out of his pocket, and the stand containing the compasses in his possession. A policeman's whistle was blown, whereupon Smith threw away the jemmy and the compasses, and both men ran away. He gave chase, and caught Smith, who was detained until a constable arrived. Esser was pursued and captured by Constable 253 C. Detective-sergeant West, C Division, informed the magistrate that both the prisoners were ex-convicts. Constable 106, of the C Division, said that on the morning in question he heard a smashing of glass, and on going in the direction whence the sound came, found that the window of the shop of Messrs. Sinclair had been broken. Seeing the prisoners run away, he blew his whistle. Mr. Kennedy committed the accused for trial.

COLOUR PHOTOGRAPHY.—Dr. A. Miethe, Professor of Photographic Chemistry at the Charlottenburg Technical High School, has been asked by the German Commissioner for the St. Louis Exhibition to send out a series of German colour photographs as examples of the advances made in this country in this art. The Berlin correspondent of the "Standard" says:—"Dr. Miethe, in a paper on the latest improvements in his process, states that the most important part was the production of absolutely lasting and highly sensitive pan-chromatic dry plates, and that the first step towards this lay in the discovery, by himself and his assistant, Dr. Traube, of a new class of sensitisers. They had found that there were sensitising properties in isocyanine. Thanks to this discovery, the Professor has been able to make pan-chromatic dry plates highly sensitive to colours. In forming his colour photographs, Dr. Miethe uses a special projecting apparatus invented by himself, which consists of a triple lantern connected with three electric lamps served by an electric current, which can be varied from ten to thirty-five amperes. These lamps light up a space of from four to twenty square metres. The condensers consist of a triple system of lenses, each having three component parts. These condensers, which enable the fullest use to be made of the light, are connected with a cooling apparatus, which prevents any harm being done by warm rays to the diapositive. An interesting feature in the apparatus is the projection objective, which possesses varying focal lengths. The whole projection apparatus is extremely delicate, and can be made to suit every size and description of picture. The pictures which will be shown by Professor Miethe at the Great Exhibition consist of four series of about fifty photographs. The first represents German viticulture on the Rhine and Mosel; the second, German forest cultivation; the third, views of different German villages; and the fourth, pictures of the Southern Dolomites and Lake Garda."

In these columns we have frequently advocated the advantages of a national photographic survey of our works of art, and it is pleasant to be able to announce that an attempt, though it be as yet without State aid, is to be made to realise this ideal. The Arundel Club is a new organisation which proposes to issue to subscribers photographs of this kind to the utmost extent made possible by the dimension of the support it receives. It begins operations under the auspices of an influential committee, consisting of Lord Balcarras, M.P., Sir Walter Armstrong, Sir Martin Conway, Professor Sidney Colvin, Messrs. Lionel Cust, Claude Phillips, Herbert Cook, John S. Sargent, R.A., Roger Fry, Charles Ricketts, and others, the hon. secretaries being Miss Rachel Ricardo and Mr. Robert Ross, of 10, Sheffield Gardens, Kensington, and the annual subscription one guinea. The club—whose name is happily suggested by the old Arundel Society, which did such good work in bygone days in the reproduction of pictures by Old Masters—proposes to deal with art objects of every kind, and recognises the need of making its photographs easily accessible to students; though, as it proposes to issue them to members only, the means by which this desirable end is to be achieved are not too readily apparent. The ordinary art student has few guineas to spend. Still, the movement deserves every encouragement. One statement in the prospectus, however, is not only uncalled for, but essentially inaccurate. The committee says that "it is only in England that no such collection has been undertaken, except in so far as it is being done by a few private individuals." This argues a singular ignorance of the subject on the part of those responsible. For many years photographs of this nature have been accumulated in the Victoria and Albert Museum, and the collection, now probably amounting to upwards of one hundred and sixty thousand prints, is well known to and constantly used by the many frequenters of the National Art Library. The sections of painting and sculpture are probably among the finest of their kind in the world, and they are accompanied by large numbers of prints illustrating architecture and every kind of applied art; while the museum possesses, in addition, something like twenty thousand negatives of a kindred nature, from which prints can be bought at cost price. We do little enough, in all conscience, for art in this country; but there is no reason why what is done should be depreciated in the eyes of the public, especially with an appearance of such authority as is now given by the names of the committee of the Arundel Club. The best thing that the club could do would be to co-operate with the museum authorities by filling up gaps in the national collection and so rendering it even more worthy than it at present undoubtedly is.

Correspondence.

- *.* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- *.* We do not undertake responsibility for the opinions expressed by our correspondents.

THE R.P.S. EXHIBITION. To the Editors.

Gentlemen,—I am directed to inform you that at the forthcoming Exhibition of the Royal Photographic Society of Great Britain, it has been determined to abolish the wall space charges in the Competitive Pictorial Section and the Scientific and Technical Section. The Council believe that the general body of exhibitors will be interested in this departure from the Society's custom, and they will be glad if you will give publicity to the change at your early convenience.—Yours faithfully,

A. W. W. BARTLETT, Secretary.

Royal Photographic Society, 66, Russell Square, London, W.C.

NOTES ON THREE-COLOUR WORK. To the Editors.

Gentlemen,—I much regret that Mr. E. J. Wall has left a scientific argument for the sake of an undignified personal attack, quite unworthy of him, and that it is therefore impossible to discuss the matter of Wollscharr 4B and similar dyes any further. But I am sure at the same time that those who have experimented commercially with such dyes have understood and appreciated my earlier remarks which led up to the discussion, and that therefore the matter can safely rest.—I am, yours faithfully,

T. THORNE BAKER.

1, Station Parade, Willesden Green, N.W.,

May 3, 1904.

[This correspondence here terminates.—Eds. B.J.P.]

PSYCHIC PHOTOGRAPHY. To the Editors.

Gentlemen,—Mr. Sterling's letter *re* "Psychic Photography" is very interesting, and should be convincing but for a few difficulties which need explanation. What or where are the "spheres" which the spirits are supposed to reside in or on, and how is it that if the spirits are in the habit of presenting themselves before the camera beside those in the flesh, we do not sometimes see something of them in our everyday work? Sometimes I have given excellent opportunities for any spirit to have made its presence known if it had been by the side of my customer, having my slide drawn waiting for a favourable moment to open the lens, and again after closing the lens the plate has sometimes remained in position for some minutes, but never have I seen the shadow of a ghost; and as to spirit light rays, where do they proceed from, if from the spheres? Perhaps they may illuminate the spirit substance, for we are told that "the spirit being less dense, etc."; therefore, having some density, it has some body or substance, and if the spirit photographs are to be accepted, the spirit body is of about the same form and size as the bodies we now inhabit, and be reflected from them in a way similar to that which we see in the case of the sun's rays which illumine our fleshy bodies, thus accounting for the decided studio lighting seen in some alleged spirit photographs, and also by a study of the direction of the said rays revealing the direction at least of the radiant sphere from whence the rays proceed. And here I would suggest that some astronomical friend should try some time to obtain a photograph of the said sphere, seeing its general direction can so easily be deduced from the photographs produced by it. But if the spirit is self-radiant then I fear all the above goes for nothing, and all those studio examples are manifestly gross impostures, as a self-radiant body would give no shadows nor round modelling, as we see on bodies illuminated by radiations other than their own. Then, again, it truly is "mysterious enough, the cap is no hindrance to the spirit light rays focussing through the lens," as should we try the effect of placing a cap of the clearest glass before our lenses we should find that unless the surfaces of the glass were well polished and plain, the focus would be greatly impaired, the light diffused, and the plate fogged all over. Really this spirit photography is a most mysterious thing, and I should not wonder that if the camera were provided by

the customer as well as the plates and dark slides, the would be so offended by the want of faith displayed by their work photographers that they would cease their manifestations altogether.—Trusting to get at "the truth" by-and-by, I remain, yours truly,
May 9, 1904.

E. WILLIAMS.

P.S.—Your correspondent from Bexhill states his disbel in ghosts, therefore is somewhat out of the present inquiry.

To the Editors.

Gentlemen,—Referring to Mr. Sterling's letter, it may save a deal of needless trouble to state that Mr. Bournsall has not a studio in Uxbridge Road, he, I regret to say, having had to go business owing to failing health and advanced age, for he is between seventy and eighty. So unwell is he that he has requested my friends not to call or even write to him, as he is unable to receive any letters. Though an uneducated man, he has done a splendid work, and has earned the gratitude of thousands.

Mr. Sterling's experiences relate to a series of seances he had nine years ago, which resulted in some very beautiful spirit photographs. The negatives are now in my collection.

In your account of my lecture on this subject at the Camera Club there is one slight error. I did not say that Sir William Crookes photographed "unseen" sitters, but that he had taken a number of portraits of a fully materialised spirit who was known by the name of Katie King. Being materialised, there was no difficulty in photographing her, as she could be seen by all present, and, in fact, carried on a conversation and even vied about for the time being like an ordinary mortal.

This could only take place through the presence of a good materialising medium, of which, unfortunately, this country possesses very few.

When it is a question of photographing spirits who are not visible to normal sight, a different phase of mediumship is necessary, and is at present very rare, and now that Mr. B. has given up, I am no one at the present time in this country who can guarantee a picture. There are several amateurs who are gradually developing and occasionally get, psychic markings on their plates, but if patience is necessary, as hundreds of negatives may be taken but few results. In the United States there are altogether about half a dozen spirit photographers who have, of course, frequently given the best of tests by the sitter recognising on the plate developed the familiar features of long departed friends and relatives who had taken this means of showing that they still lived on.

Mr. Henderson's letter is written in such a needlessly off-strain that unless he apologises I decline to reply.—Yours faithfully,
May 9, 1904.

H. BLACKWELL.

THE NORTHERN PHOTOGRAPHIC EXHIBITION. To the Editors.

Gentlemen,—Your issue of last week contains a letter signed "A Disgusted Exhibitor," and for the benefit of your readers should like to supplement the writer's statements with a few facts.

1st.—The minimum entrance fee at the Royal is 5s., and exhibitors receive a catalogue and season ticket. The minimum entrance fee at the Northern was 2s., and exhibitors received a catalogue valued at 1s.

2nd.—The price of admission to the Royal is 1s., and no payment is made for the catalogue; at the Northern was 6d., and payment for the catalogue was given on application.

3rd.—The Walker Art Gallery is the property of the Corporation of Liverpool; and regulations as to what articles may or may not be taken into the rooms are made by the Corporation, and enforced by their servants.

4th.—The cloak-room is also the property of the Corporation, managed by their servants; and a charge of one penny is made for each article deposited.

5th.—No person outside the Liverpool Society spent a penny on the success of the Northern; but those who paid the highest entrance-fees also gave many hours of hard work to ensure the success of the exhibition, and purchased their season tickets. A gentleman who, not being a member of the Liverpool Society, paid the largest sum in entrance-fees was not "A Disgusted Exhibitor." I am, gentlemen, yours truly,
Liverpool, May 9, 1904.

C. F. INNES.

THE FUTURE OF PHOTOGRAPHY.

To the Editors.

Gentlemen,—Your article in last week's BRITISH JOURNAL OF PHOTOGRAPHY on "The Future of Photography for Employés" is opportune and interesting. It is a fact that there are scores (I am tempted to write hundreds) of so-called "high-class" operators, of exceptional ability, etc., who, on being engaged, turn out to be quite incapable, save by an occasional fluke, of taking a really negative that is good in pose and lighting. The writer, with twenty-five years' experience, thoroughly agrees with you in ascribing the flooding of the photographic labour market with so many incompetents to the present system of taking artied pupils with a substantial premium by firms of wide repute. It takes years to make an ordinary individual into a good operator, and the man who has to do his way up by his own exertions, and seeing what his betters is much more likely to succeed than the one who travels the road to learning, which his parents have to line with golden promises, and then imagines he is ex-officio competent to take charge of the better-class studios in the country.—I am, yours, etc.,
MAY 11, 1904. A PROVINCIAL PHOTOGRAPHER.

APPLY Expressed.—Lady Gusher: Good-by! Thanks so much! Your pictures are charming, and so unlike your usual work!—Yours truly, etc.

It is reported that the Dowager Empress of China has consented to be photographed, in order that the people may be able to worship Imperial image, as in Japan. A Japanese photographer has received orders to attend at the Palace for the purpose.

We regret to have to announce the death, on the 8th inst., of Mr. Edward Muybridge, in the seventy-fourth year of his age. Mr. Muybridge will be remembered for his work in connection with the photography of moving bodies.

MESSRS. H. FIRMAN AND CO., of Lever Place, Staines Road, Windsor, have sent us their trade list of enlarging and finishing bromide paper, opals, and canvas in oils, water-colours, and black and white. The prices are low, and prompt delivery is promised. Photographers should write for a copy to above address.

WELL AND GOODRICH, LTD.—The above-named company has been incorporated with a capital of £1,000 in £1 shares; 500 preference shares, to adopt an agreement with S. A. Sewell, A. W. Goodrich, C. T. Hine, and to carry on the business of photographers, lithographers, etc. No initial public issue. The first directors are S. A. Sewell, A. W. Goodrich, and C. Hine. Registered office, 68, Imperial Buildings, Ludgate Circus.

ANOTHER SWINDLE.—A number of people in Walton, Surrey, have been victimised by a new method of swindling. Some individual, purporting to represent a London firm of photographers, who, he said, had a branch at Halfway Green, induced them to buy 6d. tickets, entitling them, he claimed, to be photographed at a reduced price. On calling at the shop in question the victims found that the man was known of the "canvasser's" ingenious scheme, and that sixpences had been expended in vain.

THE ROYAL ACADEMICIAN.—On the old village green of Uxbridge, Herts, a Londoner was induced by a photographer (who had been his "pitch" there) to buy a "Royal Academy portrait" of himself, frame included, for fourpence. Asked why he used the name of the R.A., the camera-man said, "I am employed during the season in Burlington House as a carpenter. Out of the season I go round the countryside taking photographs, and as an assistant at the famous institution in Piccadilly I use its glory to help me in the provinces."

WE hear that the Glasgow Eastern Amateur Photographic Association desires to improve its rooms, and, incidentally, its financial position. The photographic societies of the land have therefore been asked to contribute with shilling books of thirteen penny pink tickets for a prize drawing which will take place on August 8 next. The prizes include a marble timepiece, a rainproof coat, travelling bag, bellows, pipe, etc., and as an inducement to kindred associations a plaque is offered to the club which disposes of most books. Devious are the methods of the wily secretary. We are glad to hear that the G. E. A. P. A. has studied the Lottery Acts carefully.

Answers to Correspondents.

* * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

* * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

H. Linn, 31, Taylor Street, Woolwich. Photograph of Woolwich Arsenal Football Team.
J. A. Stelling, 60, Peckham Road, S.E. Photograph of the Rev. J. W. Ewing.
W. Thorneycroft, Wolverton, Bucks. Photograph of Royal Train passing Wolverton.
C. W. Heywood, 53, Osborne Road, South Shore, Blackpool. Photograph of a Stern at Blackpool.
H. Green, 67, High Street, Dudley. Photograph of Interior of Wesleyan Church, King Street, Dudley.
W. T. Carter, 43, Drake Street, Rochdale. Photograph of River Roach before opening.
P. Simms, 12, High Street, Chipping Norton. Photograph of Children in "Six Divine Princesses."
J. Snivas, 84, Queen Street, Peterhead. Two Photographs of J. Stuart.
J. W. Garratt, 9, Station Road, Ashley Down, Bristol. Four Photographs of Muller's Orphanage.
J. W. Garratt, 9, Station Road, Ashley Down, Bristol. Photograph of Muller's No. 3 Orphanage, Ashley Down.
H. Leake, 6, St. John's Square, Wakefield. Photograph of the Wakefield Trinity Football Team 1903-4.

FINISHING ENLARGEMENTS.—"ANXIOUS TO LEARN FINISHING" asks: "Will you, please, tell me what are the best materials to use for lightening deep shadows on the face, and for finishing bromide enlargements; generally in black and white?" In reply: An ink eraser is what is usually employed for the purpose.

DAGUERREOTYPES.—J. COLLINS writes: "I have one or two Daguerreotypes in my possession, of which I should like facsimiles made. Could you give me the address of a firm who would undertake the work?" In reply: We know of no source whence Daguerreotypes are nowadays commercially obtainable. Some reader might perhaps be able to supply the desired information.

UNEQUAL TONES.—"J. P." says: "I am sending four stained prints, and will take it as a great favour if you would say what you think is the cause of these stains. Is it the retouching medium or the printing and toning that are at fault?" In reply: Simply the toning. The prints were not kept moving while they were in the toning solution. Hence the uneven tones.

A. L. CRANCH.—Your outdoor photographs are better than the portrait you send. The latter is very ordinary. When your work has considerably improved we see no reason why you should not secure one of the vacant situations as operator advertised in our columns week by week. The supply, however, much exceeds the demand, and we do not think your work will secure you a very high salary to start with.

LENS.—TONING.—"PLATINUM" puts the following questions: "(1) What is the meaning of term $f/4$, etc., as applied to photo lenses? (2) Would he give me a simple but efficient toning formula for matt p.o.p. to produce a nice purple tone similar to what I can obtain in using glossy p.o.p.?" In reply: (1) $f/4$ means that the aperture of the lens is equal to one-fourth of its focal length. (2) Matt papers, as a rule, will not give the same tones as glossy, and they are not intended to do so. Try the bath you are using and remove the prints at an early stage.

F. LUCAS asks: "Will you kindly let me know how I can make a negative or transparency in very strong relief, a simple method?" In reply: We presume you require a relief for moulding from. If so, coat a glass plate thickly with, say, Nelson's No. 1 gelatine, dry, and sensitise it in a 5 per cent. solution of bichromate of potash, and again dry. Print under

a strong negative, and then place in cold water. The gelatine will then swell up in bright relief where the light has not acted. The relief can then be moulded from in plaster-of-paris.

"BEGINNER" says: "I have a bottle of liquid labelled 'Chlorwasserstoffsäure.' I understand it can be used in photography. It is of yellowish colour, tastes nasty, has an unpleasant smell, and gives off smoke. Can you tell me what it is?" In reply: The liquid you have is known also as muriatic acid, spirits of salts, and hydrochloric acid. It has many uses in photography, and is employed in various formulae. It is also very useful for removing stains, etc., from photographic dishes and measure glasses. We trust you have not acquired a taste for "Chlorwasserstoffsäure," as the bottle should be labelled "Poison."

COPYRIGHT QUERIES.—"ARTIST" says: "A buys a picture, including copyright, from B and sells the copyright for publishing purposes, to C during the artist's life. The artist dies. Can A, when seven years from the date of the artist's death have elapsed, photograph and publish, or give or sell permission to be published, reproductions of the pictures which remain in his possession without regard or reference to C, who is publishing a large engraving of the picture?" In reply: The copyright expires seven years after the artist's death; then anyone can copy the original painting, but not copyright reproductions of it.

GELATINE—"PHOTOPHIL" says: "(1) He would be glad to know of any make of photographic dry plates for either negatives or positives in which the gelatine has not undergone any alum or other treatment to render it insoluble. (2) Also of a gelatine which liquefies only at relatively high temperature?" In reply: (1) We are quite unable to reply to this query, as we are not in the secret of the different plate makers. (2) Cignet's gold label gelatine; or, possibly, Nelson's "X Opaque" would answer your purpose. Both are very hard gelatines. The former would probably require the higher temperature to liquefy it.

SECOND-HAND LENSES.—"G. A. T." says: "I have a Dallmeyer 2B portrait lens which I can remember for at least twenty-five years. Will you kindly inform me whether the lenses catalogued to-day are the same, or whether the makers claim any improvement. What I really want to know is, if I buy a second-hand Dallmeyer 3B, or a 3A Ross, are they likely to be the same property value as a new Ross or Dallmeyer?" In reply: This is a query that it is a little difficult to answer. Of course leading opticians avail themselves of all the improvements made in optical glass, so it may be fairly assumed that modern productions are superior to the older ones. You must keep in mind that there is always some little risk in buying second-hand goods.

F. JUGGINS says: "I am about to dispose of my business as a photographer. Does the transfer of my business deprive me of my copyright in such negatives I have specially copyrighted?" In reply: The sale of a business, which may include many copyright negatives, raises the serious question of whether a separate assignment must be made for each subject, and the general impression seems to be that this is so, though we know of no authority being quoted to this effect. An assignment on one form, giving a list of the subjects assigned, should certainly be sufficient; and there is no apparent reason why a general assignment of "all copyrights" should not answer the purpose. In the case of an action on any given copyright it would be necessary to prove that it was one of the subjects so assigned.

"TONER" says: "I should be much obliged if you could let me know of a formula for toning collodio-chloride, matt. P.O.P., sepia, portrait brown, and black, one which will give clean, even tones, and is fairly reliable." In reply: Good sepia and brown tones are obtained by using the following:—A. Sodium tungstate, 840 grs.; distilled water, 40 oz. B. Ammonium sulphocyanide, 360 grs.; distilled water, 40 oz. C. Gold chloride, 15 grs.; distilled water, $3\frac{1}{2}$ oz. Make up one hour before required: A., 20 oz.; B., 5 oz.; C., $1\frac{1}{2}$ oz. To get pure blacks use: A., gold chloride, 1 gr.; sodium acetate, 30 grs.; water, 40 oz. B., Potass chloroplatinate, 1 gr.; phosphoric acid, $2\frac{1}{2}$ oz.;

water, 40 oz. Tone prints in A. until purple, and continue toning in B. Wash prints between A. and B. in three changes of water. Use A. once only. B. can be used again and again until action is too slow. In all cases print the C.C. darker than required when finished.

STUDIO LIGHT, ETC.—"NERNST" writes: "Will you kindly answer the following questions:—(1) The best way of drying unmatted 12 x 10 matt bromide prints to stop curling? (2) Can you address the makers of the 'Nernst' lamps? Do you know how long one burns—the average, say? Can they be used successfully for portraiture in studio, or do you think the arc light is better? (3) Do you know of any firm selling cabinet photographs showing the effects of different ways of lighting studio?" In reply: (1) We have always employed the following method, which we find very satisfactory: Place the prints between blotting boards free from fluff until surface dry. Hang up by the corners, and when dry, pass a straight-edge flat ruler over the back, pulling the print sharply out under the pressure. Let this be done on a clean smooth surface of course. All tendency to curl will be entirely eliminated by this means, and if the prints are now kept in a portfolio under pressure for a time they will remain quite flat? (2) The General Electricity Company, 71, Queen Victoria Street, E.C. 4. Write them for particulars of the light. We have had no practical experience in the studio with the light, so can express no opinion. (3) We know of no firm that publish such portraits, perhaps our readers can assist.

TRADE DISPUTE.—"PERPLEXED" says: "A postcard traveller came on me last November for an order for postcards. At the time I did not decide on definitely or give an order for. He sent the order (if given) would be delivered early in January. In January the firm wrote stating they could not procure views of the town in question, but would supply cards if addresses of local photographers were given. At this time I had decided not getting them, or giving an order for, as I had already received views of the town mentioned. As I did not reply to the letter or give addresses, I considered the order cancelled. A few days ago I received a bill from the firm for the postcard which I objected to take or pay for, on the grounds that the order was not given for nor executed in the stated time by the traveller. (2) The traveller's terms were for six views, each, at 22s. per 1,000. No mention of charge for taking negatives, and which I understood would be included in the order. In addition to this price they have charged £2 5s. for negatives. Can they compel me to pay this, as there was no agreement for charge of negatives?" In reply: If the facts are as stated by you, we should think you would be justified in refusing to receive the goods. But something may have happened upon the conversation you had with the traveller. The advice we can offer is that you consult your solicitor on the matter.

** NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears on the text portion of the paper.

THE BRITISH JOURNAL OF PHOTOGRAPHY "JUBILEE NUMBER (1854-1904).

To celebrate the completion of the fiftieth year of the British Journal of Photography we shall issue on June 10 a Special Jubilee Number of the publication, which is universally recognised as the oldest and most influential of its kind in the world.

The ordinary issue of the Journal of June 10 will be more than doubled in size in the text portion, and amongst other features will include, by way of supplement, an illustrated history of The British Journal of Photography, with portraits and Biographies of the Eminent Men of Science, Journalists, and Photographers who have been identified with the conduct of the paper during the last fifty years.

As a souvenir of a unique celebration in photographic journalism the "B.J." Jubilee Number will undoubtedly be in enormous request, as it is not too much to say that the history of the paper during the half-century of its existence is most intimately bound up with the history of photography itself.

Of this Special Issue of THE BRITISH JOURNAL OF PHOTOGRAPHY many thousand extra copies will be printed, as the normal demand for the paper will be very largely augmented. Moreover, it is intended to give the Jubilee Number a specially organised world-wide distribution, so that the greatest possible publicity will be secured for the paper on the completion of its fiftieth year of existence.

EX CATHEDRA.

Psychic Photography. On Thursday evening, May 26, Mr. Henry Blackwell, whose name has recently been associated in a prominent manner with "Psychic Photography," will address the members of the London and Provincial Photographic Association on the subject, and on the same occasion will show a series of illustrative slides. The meetings of the Association, we may remind our readers, are held at the White Swan Hotel, Tudor Street, Blackfriars, London, E.C., and visitors are always sure of a cordial welcome to them. It is of interest to recall the fact that rather more than eleven years ago the late Mr. J. Traill Taylor, Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY, read a paper on "Spirit Photography" before the London and Provincial Photographic Association, which subsequently gave rise to considerable discussion and comment. In view of the fact that there has been a recrudescence of interest in this extraordinary phase of photography, we take occasion this week to reprint Mr. Taylor's paper. A perusal of it may possibly give some points to some of those desirous of joining in the discussion on Thursday night next who may be unfamiliar with what has hitherto been attempted and accomplished in psychic photography.

* * *

The Convention.

By the courtesy of Mr. F. A. Bridge, the Hon. Sec. and Treasurer of the Photographic Convention of the United Kingdom, we have received an advance copy of the book of the Derby meeting, which takes place in the week July 11 to 16 next. The frontispiece is a portrait of the President Elect, Mr. G. Herbert Strutt, from a negative by Mr. C. Barrow Keene, of Derby, and included are admirable illustrations of Dovedale, Haddon Hall, the old Smithy at Curnford, etc. Old Conventioners will no doubt appreciate a reproduction of the first Derby Convention group, taken in the year 1886, wherein some familiar photographic figures are to be seen. In the BRITISH JOURNAL OF PHOTOGRAPHY for next week we shall reprint the entire programme for the meeting. The excursions to some of the most romantic parts of Derbyshire should be immensely popular with visitors to the Convention, of whom no doubt a large number will put in an appearance. As Derby is easily accessible from all parts of England we predict a numerously attended and most enjoyable function, the success of which is assured beforehand in virtue of the fact that the President Elect and the local Executive will extend a most cordial reception to all present. Personally, we look forward to the Derby Convention as giving us the opportunity of meeting many old photographic friends and supporters of the JOURNAL.

Patent Office Work.

Much has been said and written in the main, not without justification, about the ease with which a patent may be taken out where actual novelty does not exist, while, in other countries, exhaustive examinations of the claim form a preliminary step. Yet that some examination does take place in this country is evident from a recent announcement from the Patent Office that there are vacancies for twenty-four situations as assistant examiners in the Patent Office. Those of our readers interested in patents may care to know that particulars of the examination—to be held in July next by the Civil Service Commissioners—may be obtained by sending for a form of application to that body. The address is Burlington Gardens, London, W.

* * *

Colloidal Silver.

One of the most remarkable discoveries of the late American chemist, Mr. Carey Lea, whose papers formed so valuable a feature of our pages some years ago, was that of colloidal silver. Doubt upon the conclusions he formed and the results he obtained has often been expressed, but his conclusions have usually been successfully vindicated. The latest publication of results in this direction are those of M. A. Chassevant, published in the Bulletin of the French Chemical Society. He obtained the product by mixing 500 c.c. of a 10 per cent. solution of nitrate of silver, 500 c.c. of a 30 per cent. solution of ferrous sulphate, and 700 c.c. of a solution of citrate of soda, the result being a reddish coloured deposit, which he allowed to settle for half an hour, and then filtered by means of a filter-pump. This precipitate of metallic silver possesses the remarkable property of being soluble in distilled water, and re-precipitable by alcohol, re-solution in water, and so on. The point of great interest about these results is the fact, which must now be admitted, that the precipitate of colloidal form is the metal itself. "The summary of all these facts," says the writer, "makes us admit, with Carey Lea, that all the preparations of colloidal silver contain the silver, not in a special allotropic form, but that the fine particles of silver, which were unable to become conglomerated at the moment of their production, have remained in the free state in solution."

* * *

Miniature Painting.

At one time—in the earlier days—coloured photographs were very much in vogue, and pretty high prices were obtained for the colouring. Daguerreotypes were coloured, glass positives were coloured, and paper pictures were coloured; and very good some of them were when done by good artists. Just now there seems to be a rising taste for coloured photographs as miniatures; and portrait photographers will do well to cultivate it, as it will prove a profitable branch of their business. But the work should be well done or left alone, because a badly-coloured photograph is anything but a work of art. Anent the subject of miniatures, we see that at a sale of a part of the Hawkins Collection at Christie's one day last week a miniature by Holbein of Frances Howard sold for an extraordinary high price. The bidding commenced at £470, and, after spirited competition, was knocked down for £2,700. A pair of oval miniatures of children realised £1,000. High prices for pictures are sometimes obtained in Edinburgh as well as in London. A few days ago a portrait by Raeburn was, at auction, knocked down to a Glasgow buyer for 1,175 guineas; but there was afterwards some dispute, and the picture was put up again, when it realised the not insignificant sum of 2,600 guineas. Many are complaining just now that money is scarce, but from the

above it would seem that there is still some left for picture market.

* * *

Astronomy at the Sailors' Palace.

An interesting ceremony took place Friday last when the Marquess Northampton declared the observatory and telescope for the King Edward VII. Nautical School open. The observatory is at Sailors' Palace at Limehouse, which is pretty well known as "Jack's Palace." The telescope, an equatorial, is a really new one, as it was originally made in 1874—thirty years ago—but additions and improvements have been made which bring it up to date. The instrument is of the usual form of Sir Howard Grubb's standard equatorial, with an eight-inch object glass, with an eight-inch focus. In power it is manifest that it is not equal to instruments now in use in all the principal observatories, but it is such a one that many of the important astronomical discoveries have been made. At the time it was made—thirty years ago—it would be looked upon as quite equal to the requirements of any standard observatory. The observatory and the telescope, it should be mentioned, are the gift of the late Louisa Lady Ashburton. We are not aware if the telescope will be utilised for photographic purposes; but probably it will at times, when atmospheric conditions will permit, which we fear will be very frequent. Limehouse is certainly not the ideal situation for an astronomical observatory, even if photography were not an object in view. The atmospheric conditions that usually prevail in that district are conducive to successful observations by means of photography. But there is no question that the observatory and its telescope, will prove exceedingly useful to students at King Edward VII. Nautical School.

* * *

Indecent Picture Postcards and Stereoscopic Slides.

Some months ago, it may be remembered, we directed attention to the character of many of the pictorial postcards which were to be seen in some of the shop windows, and expressed the hope that the production of such pictures would not militate against the popularity of the picture postcard, the production of which has now become an important industry. Since that time there have been several prosecutions for exhibiting for sale pictures of an indecent character. Only last week the police made two raids in the East End, and seized between eight and nine thousand of these objectionable things. In the one case the defendant had to pay 100 shillings, the costs of the court, and five guineas for the solicitor's costs. In the other the defendant was mulct in a fine of three pounds and two guineas costs. In both cases the cards were ordered to be destroyed. It is to be hoped that the vigilance of the police in this matter will put a stop to the traffic in these indecent and vulgar pictures before the popularity of the pictorial postcard becomes seriously impaired. For some two years past there has been a gradual revival in the popularity of the stereoscope. It is the very general opinion with those who can remember the time when it was once so popular in almost every house that its decadence was largely brought about by the introduction of pictures of a vulgar or indecent order. We allude to this sub-ject now because we have recently seen exhibited in some shop windows stereoscopic pictures of a very dubious character. If they were not actually indecent, they were vulgar, if not more by suggestion. This sort of thing must not be encouraged, or it will certainly militate against the stereoscope again becoming popular in good society.

**Plate
Fogging.**

A potent cause of fogging of plates, which, though we have frequently called attention to it, is still but little recognised, is one or more of the many forms of black varnish used to blacken the insides of cameras and slides. The persistence of this fogging effect, as we know to our cost, is almost incredible; we possess slides which have not been varnished or otherwise treated for years past, which have purposely been left open and exposed to a free current of air for days at a time, but in which, even yet, we should never think of leaving a plate for a much longer time than a day or two, as we know they would become fogged. Dr. Russell, a summary of whose investigations in this direction we published in these columns, gave a list of the substances the emanations from which produced this untoward effect, and the most probable acting cause on the list would seem to be turpentine, a liquid playing an important part in the manufacture of many of the black varnishes of the day. Another substance has been added to the list by Herr E. van Aubel, who finds that resin is capable of acting in the manner described by Dr. Russell. This is an important fact to bear in mind, as it also, from motives of economy, is often used to give body to varnishes, to the partial displacement of shellac. There is, however, still another direction in which its unexpected presence may be looked for. It has been notified that large quantities of resin have been exported to India, and the use for which it is suggested is the adulteration of shellac. It would be doubly hard to find this most valuable substance rendered not merely less efficient by reason of the sophistication, but also likely to become a fog producer by reason of the presence of this newly-discovered fog producer.

* * *

**A New
Photographic
Map of
the Moon.**

Photographic representations of the moon, of various sizes and in different phases, have been produced in abundance, some being purely photographs taken direct, others enlargements more or less faked, to use an acknowledged photographic term; but, so far, a complete photographic atlas had not been published till quite recently, Professor Pickering having just brought out one of great interest, especially with regard to conditions of permanency or change in the surface of our satellite, usually considered as fixed and unchangeable, but which Professor Pickering brings forward photographic proof to show a daily change in. Apart from his astronomical interest, the views will appeal to photographers. The object glass employed—the funds for which were supplied by two anonymous donors—is of extraordinary focal length—no less than 135 feet—the diameter being 12 ins. The direct negatives obtained attain, in consequence, the great diameter of 16 ins. To produce stellar or selenographical negatives of extreme sharpness, it is necessary to work under conditions of atmospheric homogeneity that are difficult to meet with very often; and to obtain such conditions the telescope was set up at Mandeville, in Jamaica, 2,080 ft. above sea level. So excellent were the atmospheric conditions that the fourscore of views, consisting of sixteen sections, each exhibited under five different phases, were completed in the short space of seven months. The author found that changes in the appearance of certain regions, brought about by variations in illumination, were so great as to render it impossible to recognise the same formation when taken, say, at sunrise and sunset, so that it became necessary to produce photographs at times between the two. Further difficulty was experienced by the misleading results which variations in the time of exposure and development brought about.

**Postcard
Exhibition.**

The little crowds which gather round the many shops in London where postcards are displayed indicate that much interest is felt in this modern method of making up a picture gallery. And it must be admitted that many of these cards are most attractive, the purely photographic ones being masterly productions, and some of the landscape designs in colour well worthy of a place in an album by reason of their artistic qualities. Such high praise cannot, of course, be extended to the mass of pictorial cards, for some are vulgar and utterly inartistic; but the producer has many needs to meet, and the best things are caviare to the majority. There is just now being held at Paris, in the Place de l'Alma, an exhibition of postcards—a *Salon* devoted to that branch of art and nothing else. Handsome prizes have been awarded by a jury with conspicuous generosity, says the Paris correspondent of the "Daily Telegraph;" and the exhibition, generally, is a success. We are told that the postcards illustrated by photogravure are, on the whole, the most artistic, although it is somewhat difficult to understand how artistic qualities can be conferred upon a picture, except in a very minor degree, by the method of production. The landscape views printed in colours are said to be remarkably good, a few of them being as effective as hand-painted water-colours. This we can quite believe, for our French neighbours have always been good at colour printing. One of the great attractions of the exhibition is a machine which prints 2,000 postcards an hour in several colours, both the back and the front of each card being impressed simultaneously. Seeing that postcards are now so popular, it might be worth the while of our photographic societies which get up exhibitions to devote a section to camera pictures of this kind.

* * *

**Photographic
Deceptions
on the
Public.**

More than once we have called attention to a fraud that is committed on the public by not a few unscrupulous photographers. It is the palming off of silver prints of the gaslight type as platinotypes, or those by a platinum process, at an enhanced price, and at such prices as, compared with those charged for ordinary silver prints, would permit, with a good margin of profit, of the genuine thing being supplied. After we last called attention to this subject we received a letter from the Platinotype Company, saying they were taking legal opinion as to the best way of preventing the passing off of silver prints as platinotypes. We are now given to understand that some photographers are now, instead of using the word "platinotypes," adopting the word "platinos" on their receipts. This the general public will, usually, take to mean an abbreviation of the word "platinotypes," and assume that they are receiving, for the extra price they pay, genuine platinum pictures, while they are really supplied with silver prints. We have always looked upon the term "platinotype" as a misnomer, inasmuch as the prints contain no platinum whatever—they are silver prints pure and simple. It would seem that this misleading of the public is not entirely confined to platinum. The other day we looked at a photographer's show cases and noticed on one side of the entrance a show case of cabinet specimens labelled "Ivory finish, Three for two-and-sixpence." On the other side was another case with specimens, of the same size and smaller, trimmed to long ovals or rounds, mounted on coloured boards; these were silver prints on matt paper, toned to a brown or sepia colour, and were described as "Carbon tones. Three for seven-and-sixpence"—three times the price of the full size cabinet pictures. The lay public, in paying three times the price of ordinary prints, would naturally surmise that they would receive

veritable carbon pictures, while they would be supplied with silver prints. For the credit of photography and reputable photographers, it is very desirable that this system of misleading—we do not use the term fraud—should be put a stop to. The Merchandise Marks Act would no doubt do so if put into force; but who is to do it? This is a matter we should suggest that the Professional Photographers' Association should take into consideration for the benefit of reputable members of the craft. Both the carbon and the platinotype are processes of undoubted permanency, while the stability of all silver is more or less dubious, and it would be unfortunate that the reputation of the two former processes should be sullied in the eyes of the public by their having silver prints foisted upon them while they are paying, as they imagine, for genuine carbon or platinum ones.

* * *

Hope for Snapshotists. When it first began to be realised that the gelatine plate was so rapid in its action that a picture could be taken whilst the camera was held in the hand, the idea was entertained that such a method of securing pictures with an instrument disguised to look like something else would be of enormous service to the police. So the first hand appliances for taking photographs were known as detective cameras. We now know well enough that a photograph which detects anything is quite a rare thing. The presence of a particular person among a crowd has occasionally been proved by a tell-tale photograph, but this has been by accident and not by design of the photographer. The detective idea has long ago been discarded as an aid to the suppression of crime; but we have still with us the hooligan snapshotist, whose delight it is to take pictures of his fellow-creatures under equivocal circumstances. If this pest can only secure the picture of somebody in a position or under conditions which would be the last in which the victim would choose to be pictorially represented the hooligan is happy. Like his brother of the pavement, his notion of joy is to make others suffer; that, indeed, seems to be his one aim. Possibly persons of his class do not read the newspapers very thoroughly, and content themselves with a glance at the police reports and the sporting notes. But if their studies should extend to the shorter paragraphs which fill up odd corners of the pages they may have lighted upon an item which will raise hopes in their breasts of fresh worlds to conquer. A worthy doctor who lives at Gloucester has issued a pamphlet advocating the employment of skipping as an unsurpassed form of home gymnastics. He tells his readers that that exercise is of special value as a means of correcting the weakness of the heart, which is apt to occur in persons of sedentary life, and that it is an unequalled resource for those who wish, at no appreciable expense and with little expenditure of time, except at odd moments that are at the command of everyone, to supply the lack of outdoor exercise which those of quiet occupations suffer from. The doctor is no doubt right, and is but following the example of the great Abernethy, who would sometimes in his rude manner send away nervous patients with the intimation that instead of coming to him they should go and buy a skipping-rope. So we may expect that many persons will follow this advice, and in the intervals of writing, reading, and other studious occupations will run into their gardens and skip. Here comes in the opportunity for the photographic hooligan. He will haunt empty houses in order to secure pictures of persons skipping in adjoining gardens, and if he can only catch a well-known politician, a clergyman, or a judge on the hop he too will "leap like a hart" in his delight. And, of course, such pictures of well-known men would have a considerable market value. At present there is no law to prevent a

snapshot of a man or woman being dealt with commercially, but if skipping becomes common, and the action is the subject of surreptitious photography, the law will have to step in and put a limit upon the work of the hooligan. Skipping or no skipping, it would be a very good thing if there were some means of preventing the carriers of hand cameras from committing breaches of good taste.

* * *

Patent Medicine Photography.

It is recorded of the late Mr. Holloway who was the first of the great nostrum advertisers, that he started with a capital of only one hundred pounds, and that he spent nearly every penny of it in advertising his pills. As everyone knows he died a very rich man, and as he spent the bulk of his fortune in good works—of which the Holloway Sanatorium and the Holloway College are splendid evidences—his name should be revered with those of all other public benefactors. Success breeds imitation, and now the patent medicine vendors can be reckoned by the score, and, where Holloway spent hundreds, his followers spend thousands upon advertising their wares. But a pushing man in the days must adopt new methods, or he is quickly left behind in the race for popularity, and the newest plan of advertising a medicine seems to be the illustrated booklet. Such a publication lies before us, by which we mean that it rests before us in a reclining posture, for we have no reason whatever to doubt its strict veracity. It is a model of succinct statement and apposite illustration, and as the pictures are taken from photographs it would serve as an admirable guide for the compilation of a lantern lecture. We must not, of course, quote it by name, nor must we give the actual names of those who figure in the volume, for we might inadvertently trespass upon the law of libel or copyright; and, even if we did neither the one nor the other, we should certainly tread upon the susceptibility of our advertising manager. We can give, therefore, on a garbled account of this interesting publication—interesting to us and to our readers by reason of its indication of somewhat new application of photography. It has a picture on the cover and a title something like this: "The Marvellous Story of Mary Creegan." There is not a word about medicine, or any hint of the kind, until you get well on into the volume, when you read with solicitude that the heroine has something the matter with her internal anatomy. No one knows what is the nature of the strange disease. She is sent to the County Hospital (first slide, County Hospital exterior), and, although the doctors and nurses do all they can for her (second slide, heroine in bed surrounded by weeping staff), she gets no better. She is moved to another hospital (third, picture of other hospital), but her malady increases, and she is given up for lost (fourth, picture of cemetery). By a lucky accident her friend, Mrs. Smith, calls upon her, and asks her whether she has ever tried "Dr. Lucas's lilac lozenges for lopsided lunatics." She does try them, and after taking one box of the precious morsels she is restored to full health and dances about the hospital wards. Here follow pictures of the crutches she discarded, of the spinal board which she was about to convert into a motor-car, of the leather jacket in which she was for months encased, which will now form the nucleus of a fashionable corset, and of the many other melancholy memorials of her weary life in the two hospitals. There are other stories in the book quite as touching, with illustrations of the same nature. All the pictures are taken from photographs, and as a photograph is always, or nearly always, a correct representation of what it purports to illustrate, the booklet is a most convincing one. It will no doubt convince the large class for whom it is intended and will stimulate the popular idea that medicine can

urgery have much to learn from the compounder of the black nostrum.

THE WEATHER PLANT.

no busy worker, with the exception, perhaps, of the farmer and the umbrella manufacturer, are the vagaries of the weather more important than they are to the photographer. To the professional bad weather may mean a serious loss; to the amateur it brings sadness and disarrangement; while to the platemaker, as well as the alarmer in photographic material, a rainy season, such as experienced last year and the year before, means a terrible reduction in turn-over. The same may be said with regard to the drapery and other trades, which depend much upon seasonable changes of clothing and the caprices of fashion for the prosperity of their business. It is, indeed, a matter of enormous importance to us all that our knowledge of climatic changes—which is at present limited—should, if possible, be increased. Unfortunately, science holds out very little hope for us in this direction. We have various descriptions of barometers, but these, alas! give us no more than an indication of the weight of the atmosphere, as their name, indeed, implies, and we know how unreliable in its prognostications the home barometer is liable to be. By means of correlating observations from various points, as is now possible by the aid of the telegraph, barometrical readings furnish those forecasts which are published in the daily journals, and although these have been proved trustworthy to a certain extent, they are by no means infallible. What we want is a means of foretelling the state of the weather quite a month ahead, so that we could govern our respective arrangements accordingly; but at present there is no hope of such a boon being vouchsafed to us. Other nations have their regular rainy season, and can invest in watertight boots and clothing with a sure prospect that it will come. But our rainy season is always with us, and ready to pour out the vials of its wrath upon our unfortunate heads.

Among the many contrivances which have been made for guessing the kind of weather that is coming to us are many which do no more than inform us that the air is in a hygroscopic condition. There used to be sold a common form of weather toy, which represented a little house with two doorways, out of one of which came a man when the rain was at hand, and out of the other a woman when fine weather might be expected. This depended altogether upon the amount of moisture in the air, the motive power which swayed the see-saw upon which the figures stood being a piece of twisted catgut. The flag of sea-weather was another instance of a hygroscopic substance being used for weather prediction. In India there are a number of plants which get flaccid in moist air, and these are often used in the same way.

But there is one growth which, by its alleged virtues, has earned the name of "weather plant," and a good deal of correspondence in the "Times" has recently centred upon it. As usual in such cases, there are differences of opinion as to its merits, and we propose to review these, so that our readers may judge for themselves as to its efficacy or the reverse.

The plant is described as a tropical weed, and is technically known as *Abrus precatorius*. It has found a strong advocate in Professor Nowack, of Vienna, who, as long ago as the year 1888, published the outcome of his experiments with the plant, with the result that our authorities in Kew investigated the matter. The results of their experiments will be referred to presently. Professor Nowack

claims that during the Vienna Jubilee exhibition he was able to make forecasts, by means of this plant, from hour to hour, and two or three days in advance, for six months, and that their correctness caused general surprise. He had the same success in Bohemia, and Moravia, and the local authorities as well as the agricultural societies gave him testimonials to the efficacy of his method of forecasting. The Austrian Admiralty, after trying the system, gave the professor a testimonial in which occurs the following statement. "The results which you have obtained are undoubtedly such as to prove that by your system the weather can be prognosticated, not only with certainty but for a long time in advance. . . There can exist no doubt that this discovery, if used methodically, is of far-reaching importance to meteorology."

The weather plant and its behaviour again came up for consideration at a recent meeting of the Foreign Press Association at the rooms of the Society of Arts, and although the assembly had no connection with the Society beyond meeting in its theatre, such a number of inquiries about the plant have since been addressed to the Secretary, Sir H. Trueman Wood, that he has been moved to write to the "Times" to tell briefly what he knows about the matter.

He tells us in this communication that a very careful investigation into the powers of the weather plant was carried out at Kew. The plant, it seems, is very sensitive to changes of temperature and variations of light, and we presume that it shows this sensitiveness by a vigorous or a drooping appearance. For about a month careful observations were made, and Professor Nowack prepared, from the behaviour of the plant and the movement of its leaves, a series of forecasts, which were subsequently compared with reports of the actual weather experiment. Between these there appeared to be no correspondence, and the Kew authorities were convinced that any connection between the behaviour of the plants and the future weather, either local or distant was entirely imaginary. For further information readers of the "Times" are invited to refer to the "Kew Bulletin" No. 37, which is devoted entirely to the weather plant. From this it would appear that *Abrus precatorius*, which is so reliable abroad, is of little use in this country, a thing which does not excite our surprise, for we have long known that the English weather, and its ways are past finding out.

Professor Nowack, however, takes quite a different view of the matter, and very plainly indicates that his protégé did not have a fair trial at the Gardens of Kew. The investigations and tests, he says, were neither very exhaustive nor very careful. They only lasted for eight weeks, whereas at least a year should have been devoted to them. He complains that the primary conditions of the sensitiveness of the plants and the observations were not fulfilled. The right temperature was not kept up, and the plants "caught cold" in consequence, they became less sensitive—in fact, they died off. Another complaint he makes is that he was not permitted to continue the observations during the night, when the plant is not influenced by daylight, to which it is most susceptible. He also tells us that of 145 weather forecasts made under these unfavourable conditions, seventy were correct and twenty-five nearly correct. When physicians disagree, who shall decide?

The weather plant, according to Professor Nowack, is also capable of predicting seismic and other disturbances; and he claims that during these experiments at Kew he actually predicted, twenty days before it occurred, a disastrous fire-damp explosion, which took place at Longton, in Staffordshire. We regret that in his letter he is not a little more precise upon this point. If he means that he actually spotted the place of a coming disaster of the kind,

the weather plant should certainly be adopted in our country, and in every other country where coal is mined. But if it merely gives an indication that an accumulation of fire-damp may be looked for, the barometer will afford the same information, and it is not of much more significance than a prophecy in "Moore's Almanac."

So it remains an open question whether this plant is useful to us as a forecaster of meteorological phenomena or not. One thing, at least, we glean from the correspondence, and that is that the plant must be kept in a hot-house, so that the right temperature for it may always be maintained. This condition would certainly limit its usefulness, for comparatively few persons are furnished with such conveniences. In towns and cities hot-houses are almost unknown, except on the premises of florists, and they are not likely to add the work of the meteorologist to their ordinary business.

But even supposing that the weather plant will consent to do all that Professor Nowack claims for it, should we be much better off? Most of us do not care so much for forecasting the weather as we do for getting some kind of control over its vagaries. It may be a satisfaction to some persons to know that a small deluge may be expected within the next twenty-four hours; and if they have a plant or something which will ominously shake its head as a warning, they will feel supremely happy. For our part, we should not be content unless we had the power of shunting the deluge to a convenient time, say, the middle of the night. When science can give us a helping hand in this direction, we shall be truly grateful. We have all heard how, in some places abroad, rain has been brought down by the firing of cannon, and hailstorms have been rendered innocuous in wine-growing districts by the explosion of aerial bombs. But no one, as far as we can ascertain, has ever contrived a means for securing fine weather. Here is a fine field for the inventive mind. If some ingenious one will only see his way to hit upon an effectual method of securing this boon, the photographers will be among the first to give his scheme any support which it may require.

MESSRS. NEWTON AND Co., the opticians, of 3, Fleet Street, who have held appointments to the Royal Family continuously since 1844, have this week been honoured by a warrant of appointment as scientific instrument makers to H.R.H. the Prince of Wales.

PHOTOGRAPHERS in the Midlands will have an excellent opportunity of seeing the interesting exhibition of American work now being shown by Kodak, Ltd., at 43, Clerkenwell Road, London, E.C., at the forthcoming Convention, as arrangements have been made to include the pictures in the Trade Exhibition to be held in the Albert Hall during the Derby Meeting, July 11-16.

To ensure the proper compliments being paid to Princess Alexandra of Teck when passing the military guards in Aldershot Sir John French has given directions that a photograph of her Royal Highness be hung in the regimental libraries so that men going on guard can make themselves acquainted with her features.

THERE were some attractive exhibits of a partly geological, partly geographical, character shown at the recent conversation of the Royal Society. One of the most attractive of these consisted of two series of photographs shown by Mr. Francis Fox. The first series was illustrative of the operations at the Simplon Tunnel. There were some fine transparent stereoscopic views of the interior of the tunnel; there were also specimens of the cutter, of the Brandt Hydraulic Drill, by means of which unprecedented progress is made producing no dust, whereby miners' phthisis is avoided. The other series shown by the same exhibitor was illustrative of the Victoria Falls of the Zambesi, including some stereoscopic and other views of the Falls. There was also a photograph of the arched cantilever bridge, with a span of 500ft., now being constructed across the gorge. It will form the great gateway into the interior of Central South Africa. The lantern illustrations by Mr. Fox of these two vast enterprises formed one of the most attractive exhibits in the lecture rooms.

"SPIRIT PHOTOGRAPHY," WITH REMARKS ON FLUORESCENCE.

[Appended is the paper on "Spirit Photography," by the late Mr. J. Traill Taylor which reference is made in our "Ex Cathedra" Notes this week. The paper was originally read before the London and Provincial Photographic Association, March 1893.—Eds. B.J.P.]

THE presence of smoke may be considered as implying the existence of flame. Spirit photography, so called, has of late been asserting its existence in such a manner and to such an extent as to warrant competent men making an investigation conducted under stringent test conditions, into the circumstances under which such photographs are produced, and posing the fraud should it prove to be such, instead of poisoning it as insensate because we do not understand how it can be otherwise a position that scarcely commends itself as intelligent or philosophical. If in what follows I call "spirit photography" instead of psychic photography, it is only in deference to a nomenclature that extensively prevails and not as offering a surmise from any knowledge of my own as to what is matter and what spirit, or the distinction between mind, spirit, and matter, for, in truth, I don't know. I approach the subject merely as a photographer.

ORIGIN OF "SPIRIT" PHOTOGRAPHY.

Before I proceed, a few words on the origin of spirit photography may not be out of place. In March, 1861, W. H. Mumler, the principal engraver in the employ of Bigelow Brothers and Kennard, the leading jewellers of Boston, when while away an idle hour as an amateur photographer, had a form other than that of any one present developed on his collodion plate. He surmised that it arose from an image having been previous on the plate, and its having been imperfectly cleaned off. Subjected to a more thoroughly cleaning, the form again appeared more strongly marked than before, and he could offer no other explanation than the one given. It got noised abroad through the Press that a spirit had been photographed, and although Mumler strove to suppress the misrepresentation, as he regarded it, yet he eventually succumbed to popular demand, and took two hours a day from his regular work, devoting this to photography. This he had to extend to the whole of each day, entirely discarding his regular profession. Many men of eminence sat to him, most of whom he did not know at the time. He seems to have encouraged his sitters in the adoption of such test conditions as they deemed satisfactory. The figure that usually appeared on the plate with the sitters were, if rightly infer, those on whom the sitters' minds had been set. That eminent portrait photographer, Mr. Wm. Black, of Boston, so well known all over the world as the inventor of the acitrate bath, undertook to investigate the bona-fides of Mumler's methods. Through a friend, who had just previously sat at a sitting, Black offered fifty dollars if Mumler would operate in his presence and obtain a picture. Invited to call on the acute Black critically examined camera, plate, dippers and bath, and had his eye on the plate from the moment preparation began until it was sensitised and locked in the dark slide, removing it himself from the camera, and carrying it into the dark room, where, on development, a figure of a man was seen leaning on B.'s shoulder. Black was wonderfully stricken, and got away the negative, no charge whatever having been made. Mumler now claimed publicly to be a spirit portrait photographer, and as such he eventually opened a studio in New York, having previously satisfied Silver, Gurney, and other photographers as to the genuineness of his claims, never hesitating to operate in their galleries if required, and with their apparatus and chemicals. Mumler was arrested in New York; whether on the ground of witchcraft or of endeavouring to obtain money under false pretences, I am at present uncertain, but his trial was the sensation of the day, and numerous witnesses were examined. He was honourably acquitted.

SOME INVESTIGATORS OF THE SUBJECT.

In this country, several who are amateur photographers have

investigated this subject with more or less success. These include some F.R.S.'s, scientists, artists, and others. I question whether any have so persistently done so as the late Mr. John Beattie, of Clifton, and his friend, Dr. Thompson. Mr. Beattie was a skilled professional photographer of the highest eminence, who sometimes, prior to his death, had adopted the views of the spiritualistic school. The figures he obtained on his plates were much blurred in outline, some being misty in the extreme. I possess some two or three dozen of these taken in or in the presence of, Mr. Beattie, whose intelligence, honesty, and powers of observation no one would venture to doubt. Many such photographs are claimed to have been produced by Hudson, a professional photographer, formerly of the Holloway Road, and I submit for examination a work by the late Miss Houghton, containing fifty-four of Hudson's spirit photographs.

There are many ways by which, assuming the genuineness of any one of all spirit photographs hitherto produced, the curious article may be made even better than any alleged real ones I have yet seen. A plate secretly impressed previously to being placed in the camera, fulfils the condition; so does one at the back of which is placed a phosphorescent tablet in the dark slide. Pressure on the surface, such as by that of a Woodbury relief film, also causes a developable image; in short, trickery in a whole variety of forms may and has been impressed into the service.

PHOTOGRAPHING THE INVISIBLE.

The higher department of fluorescence may with success be employed. Here is something to which believers in the visibility of spirit forms to a camera are quite welcome. At the time, and apropos to the Mumler trial in New York, I wrote at a good many absurd things had been said pro and con on the subject; but a writer in the latter category, who asserted that anything that is visible to the eye of the camera, and thus capable of being depicted by photography, must therefore be necessarily be visible to the human eye, was surely ignorant of that important branch of physics popularly known as fluorescence. Many things are capable of being photographed which to the physical eye are utterly invisible. Why, for that matter, a room (visually dark) may be full of the ultra-violet rays of the spectrum, and a photograph may be taken in that dark light. Objects in a room so lighted would be plainly visible to the lens of the camera—at any rate, they could be produced on the sensitive plate, while at the same time not a atom of luminousness could be perceived in the room by any person possessing ordinary or normal vision. Hence the photographing of an invisible image, whether it be of a spirit or a lump of matter, is not scientifically impossible. If it reflect only the ultra-violet rays of the spectrum, it will be easily photographed, although quite invisible to the sharpest eye. Again, Cromwell F. Varley, F.R.S., well known as one of the most eminent of electricians, says ("Eclectic," June, 1871), when passing a current of electricity through a vacuum tube, the results of which were indicated by touches of light about the tubes: "In one instance, although the experiment was carried on in a dark room, this light was so feeble that it could not be seen, and the operators doubted if the current were passing, although photography was at work, and in thirty minutes a very good picture was produced of what had taken place. This," he says, "is a remarkable fact; indeed, it borders on the wonderful that a phenomenon invisible to the human eye should have been, so to speak, seen by the photographic lens, and a record thereof kept by chemical agency. It is highly suggestive, and we may anticipate that it will be turned to good account by practical philosophers."

FLUORESCENCE.

Some very striking phenomena in photographing the invisible may be produced by the agency of fluorescence. Figures depicted upon a background by one or other of certain substances

I shall presently name, although invisible to the eye, may become visible to the camera. Of these, the best known, although not the most effective, is disulphite of quinine. Such a solution, although to the eye it is colourless like water, is to the camera as black as ink. Fill three phials respectively with water, quinine, and common writing ink, and you have two whites and one black; but photograph them, and you have two blacks and one white. The camera has reduced the transparent quinine solution to the colour of the ink. Those of you who may care to experiment in this direction, please take notice that the quinine must be acidulated with sulphuric acid, and that hydrochloric acid, even a small trace, will destroy this property. Among other substances that are fluorescent, or that change the refrangibility of rays of light, are mineral uranite, certain salts of uranium, canary glass, alcoholic solution of chlorophyll, rescaline, tincture of stramonium seeds, and of turmeric. There are others known to be still better, but my experiments in this direction are yet too incomplete to warrant my even indicating them.

Let me for a moment enter the realm of speculation, and assume that there are really spirits invisible to the eye but visible to the camera and to certain persons called seers or clairvoyants only. Might we not suggest that there is some fluorescent compound in the eyes of such persons not present in those whose eyes are normal, and that it is to this they owe their seeing powers? Some of you may probably be aware that Dr. Bence Jones and other philosophers have actually established the fact of such fluorescent substances being found in some eyes. May this throw any light upon the recognised fact of certain animals being able to see in the dark?

When the subject of fluorescence is more thoroughly investigated (it is a discovery of Sir D. Brewster, who was followed by Herschel and Professor Stokes, and is as yet but of yesterday), we may hope for a vast accession to our knowledge of subjects as yet very slightly understood.

At the Bradford meeting of the British Association for the Advancement of Science, in 1873, Dr. Gladstone, F.R.S., demonstrated before the Mathematical and Physical Section what I have said respecting invisible drawings on white cards having produced bold and clear photographs when no eye could see the drawings themselves, and I brought away back to London these photographs, and, for aught I know, may have them still.

A LADY'S JOKE.

To prevent this disquisition from being too dry, I will here introduce a fanciful sketch I wrote apropos of Dr. Gladstone's demonstration at the time mentioned:—

A mischievous young lady of scientific proclivities who attended the meeting of the British Association, and who was addicted to practical joking, listened attentively to Dr. Gladstone's observations upon the properties of quinine referred to, and having carefully noted the discussion that followed, reasoned within herself thus: If solution of quinine can make invisible marks on paper which will come out black on a photograph, it ought to do the same when applied to the skin. So she procured some of this solution, and upon her fair brow she painted with it a death's head and cross bones. These, of course, were invisible to human vision. Thus prepared she went to a photographer to have her portrait taken. All went right until the operator went in to develop the plate, when she soon heard an altercation between the photographer and the attendant boy, in which it was evident that the latter was being charged with having coated an old or dirty plate.

A second negative was taken, with this result, that the operator, after bestowing a puzzled, affrighted look at the lady, rushed downstairs to the principal of the establishment. Both returned to the dark room, and a third negative was taken, when it became evident that intense excitement was being produced in the dark room. After an excuse to the lady about

there being electricity in the atmosphere which had affected the chemicals, she was requested to sit once more.

Scarcely had the plate been developed when both photographer and assistant rushed out from the dark room, pale and excited, and explained that on the brow of the sitter in each negative was emblazoned the insignia of the King of Terrors. The negatives were produced, leaving no doubt of the fact. What was to be done?

The sitter hinted something about not being disposed to be made a fool of by one who she was satisfied was a spirit photographer, and that she, for one, would not allow herself to become the victim of such absurdity. This upset the equanimity of the photographer, who expressed his earnest conviction that she was an emissary and personal friend of the common enemy of mankind.

"I shall look in again to-morrow," said the lady, in her sweetest tones, "if you promise not to play any of your silly ghost tricks upon me."

"Not for ten thousand worlds," said the artist, "shall you ever set foot within my studio again."

"Oh," she laughingly rejoined, "I shall drop in through the roof and visit you some day when you are disengaged"; and with that she departed.

"I knew it!" gasped the photographer. "I felt a sulphurous odour the moment I came near her. Send immediately for my friend, the Rev. —, and get him to offer prayer, and free the studio from the evil influences remaining after a visitation from one whose feet, although clad in boots, would, if examined, be found to be 'cloven.'"

SOME PERSONAL EXPERIMENTS.

For several years I have experienced a strong desire to ascertain by personal investigation the amount of truth in the ever-recurring allegation that figures other than those visually present in the room appeared on a sensitive plate. The difficulty was to get hold of a suitable person known as a sensitive or "medium." What a medium is, or how physically or mentally constituted to be different from other mortals, I am unable to say. He or she may not be a photographer, but must be present on each occasion of trial. Some may be mediums without their being aware of it. Like the chemical principle known as catalysis they merely act by their presence. Such a one is Mr. D., of Glasgow, in whose presence psychic photographs have long been alleged to be obtained. He was lately in London on a visit, and a mutual friend got him to consent to extend his stay in order that I might try to get a psychic photograph under test conditions. To this he willingly agreed. My conditions were exceedingly simple, were courteously expressed to the host, and entirely acquiesced in. They were, that I for the nonce would assume them all to be tricksters, and, to guard against fraud, should use my own camera and unopened packages of dry plates purchased from dealers of repute, and that I should be excused from allowing a plate to go out of my own hand till after development, unless I felt otherwise disposed; but that, as I was to treat them as under suspicion, so must they treat me, and that every act I performed must be in presence of two witnesses; nay, that I would set a watch upon my own camera in the guise of a duplicate one of the same focus—in other words, a would use a binocular stereoscope camera and dictate all the conditions of operation. All this I was told was what they strongly wished me to do, as they desired to know the truth, and that only. There were present, during one or other of the evenings when the trials were made, representatives of various schools of thought, including a clergyman of the Church of England; a practitioner of the healing art who is a Fellow of two learned societies; a gentleman who graduated in the Hall of Science in the days of the late Charles Bradlaugh; some two extremely hard-headed Glasgow merchants, gentlemen of commercial eminence and probity; our host, his wife the medium, and myself. Dr. G.

was the first sitter, and, for a reason known to myself, I used a monocular camera. I myself took the plate out of the packet just previously ripped up under the surveillance of two detectives. I placed the slide in my pocket, and exposed it by magnesium ribbon which I held in my own hand, keeping one eye, as it were, on the sitter and the other on the camera. There was no background. I myself took the plate from the dark slide, and, under the eyes of the two detectives, placed it in the developing dish. Between the camera and the sitter a female figure was developed, rather in a more pronounced form than that of the sitter. The lens was a portrait one of short focus, the figure being somewhat in front of the sitter was proportionately larger in dimensions. I submit this picture. It is, as you see, a lady. I do not recognise her or any of the other figures I obtained as like any one I know, and, from that point of view, that of a mere investigator and experimentalist, not caring whether the psychic subject were embodied or disembodied.

Many experiments of like nature followed; on some plates were abnormal appearances, on others none. All this time Mr. D., the medium, during the exposure of the plates, was quite inactive. After one trial, which had proved successful, I asked him how he felt and what he had been thinking of during the exposure. He replied that his thoughts had been mainly concentrated upon his chances of securing a corner seat in the smoking carriage that night from Euston to Glasgow.

HOW THE PSYCHIC FIGURES BEHAVED.

If the precautions I took during all of the several experiments, such as those recorded, are by any means what you thought to have been imperfect or incomplete, pray of you to point them out. In some of the experiments I relaxed my conditions to the extent of getting one of the plates to present to lift out from the dark slide the exposed plate and transfer it to the developing dish held by myself, or to let a plate from the manufacturer's package into the dark slide held in my own hand, this being done under my own eye, which was upon it all the time; but this did not seem to interfere with the average on-going of the experiments.

The psychic figures behaved badly. Some were in focus, others not so. Some were lighted from the right, while the sitter was so from the left; some were comely, as the dame shall show on the screen, others not so; some monopolised the major portion of the plate, quite obliterating the material of the sitters; others were as if an atrociously-badly vignetted portrait or one cut oval out of a photograph by a can-opener, or equally badly clipped out, were held up behind the sitter. But here the point: Not one of these figures which came out so strong in the negative was visible in any form or shape to me during the time of exposure in the camera, and I vouch in the strongest manner for the fact that no one whatever had an opportunity of tampering with any plate anterior to its being placed in the dark slide or immediately preceding development. Pictorially they are vile, but how came they there?

THE STEREOSCOPIC CAMERA IN USE.

Now, all this time, I imagine you are wondering how the stereoscopic camera was behaving itself as such. It is due to the psychic entities to say that whatever was produced on one half of the stereoscopic plates was reproduced on the other, alike good or bad in definition. But, on a careful examination of one which was rather better than the other, and which now about to be projected on the lantern screen for your examination, I deduce this fact, that the impressing of the spirit form was not contemporaneous with that of the sitter. This I consider an important discovery. I carefully examined one of the stereoscopes, and found that, while the two sitters were stereoscopic per se, the psychic figure was absolutely flat. I also found that the psychic figure was at least a millimetre higher up, in one than the other. Now, as both had been simultaneously exposed, it follows to demonstration that, although

both were correctly placed vertically in relation to the particular matter behind whom the figure appeared, and not so horizontally, this figure had not only not been impressed on the plate simultaneously with the two gentlemen forming the group, but had not been formed by the lens at all, and that, therefore, the psychic image might be produced without a camera. I think this is a fair deduction. But still the question obtrudes: How come these figures there? I again assert that the plates were not tampered with by either myself or any one present. Are they crystallisations of thought? Have lens and light really nothing to do with their formation? The whole subject was mysterious enough on the hypothesis of an invisible spirit whether a thought projection or an actual spirit being really here in the vicinity of the sitter, but it is now a thousand times more so. There are plenty of Tycho Brahes capable of applying details of observation, but who is to be the Kepler that will from such observations evolve a law by which they can be satisfactorily explained?

In the foregoing I have confined myself as closely as possible to narrating how I conducted a photographic experiment open to every one to make, avoiding stating any hypothesis or belief of my own on the subject generally, and it only now remains to exhibit the results, bad and fraudulent-looking as they are, on the screen.

J. TRAILL TAYLOR.

Exhibitions.

PLYMOUTH PHOTOGRAPHIC SOCIETY.

Our vigorous Society has been resting for a while, and now, after a period is past, has set to work in good heart and spirit. The present exhibition, opened by the Worshipful the Mayor of Plymouth (Mr. H. Hurrell), on Wednesday afternoon, May 11, with a ceremony and an excellent attendance, is one that does the Society credit in every possible way. The actual number of entries is greater, though, in sooth that is not always a gain, nor a sign of going forward, but, what is more to the point, the advance is so in quality, both in the contributions of the outsiders and of the members. The room at the Athenaeum, the building connected with the Plymouth Institution, and where the Society is fortunately well housed, is excellent for its purpose—of good shape, lofty, and well lighted, with a top light, day and night. With the experience of past years behind, the Committee has boldly tackled the question of background and arrangement, and the hanging and decorative effect are in advance of any exhibition that has been held in connection with the Society. The whole can be comfortably viewed, and there is no crowding in the hanging, nor is it necessary in the inspection of the prints themselves. The quiet style of the panelling that has been adopted, and the admirable division of the classes tend to great comfort in viewing the prints and making note of them.

The judges all are men of mark, admirably well qualified persons for their work, and, in every instance, by natural leaning and by training, very favourable to the pictorial side of photography. Their decisions, as among judges in all exhibitions, are not acquiesced in all round. Whenever did a set of judges please everybody? Their leaning to the pictorial will, of course, explain some decisions, which could no doubt have been otherwise had the triad been strangers on the technical side of photography. The gentlemen who acted were: Mr. G. H. Emerson, B.A., M.B., Cantab., R.P.S.; Mr. Baragwanath, whose reputation as a water-colour artist has been recognised by Royal circles; and Mr. F. Shelley, A.R.C.A., Head-Master of the Plymouth Corporation Technical School of Art, and an exhibitor at the Royal Academy.

Landscapes, seascapes, and river scenery compose Class A (Open), a very creditable entry of over thirty. Daniel M. Filshell has secured a silver medal with a print, entitled "Evening" (22), but the suggestion of the hour is carried too far, so that the whole is dark and heavy, with a sky lit up in part, and which is very nearly all that is clearly discernible. A bronze medal is secured by F. Warland Andrew, for "The Close of an Autumn Evening" (6), an atrociously flat, diffused, and "billowy" effect, that is not very enjoyable to look at. The sky is as flat as a wall, and has no atmosphere or

gradation. J. E. Latham, for "Eventide" (7), is given a bronze medal, and of the medalled prints, we should have been inclined to put this first, for it is more enjoyable than the others, with its old buildings and trees, though it, too, is of the cult of indistinctness. This exhibitor has also a certificate for his "A Deep Still Pool" (2), which, while strong, has the shadows too deep. More enjoyable in every way, to most people, is Arthur Marshall's "The Garden of Sleep" (25), for which he has secured a certificate. This delightful old corner in a churchyard, with its tangle of wild blossoms, and the dim, soft outline of the centuries' old church, make the rendering a very artistic and telling one, and such as might well have had fuller recognition. The same exhibitor has an equal distinction for another print of "Sunshine" (28), a mere study of a cobble pavement and a wall, across both of which the soft shadows fall in a very real way. This is clever work. A. Percival W. Grave's "Hailstorm Passing Over Bonaduz (Grisons)" (12) is a rather charming study of a winding street in a quaint Continental town, of which the hailstorm, indicated by a black sky, is but a passing incident, throwing up the tall houses in relief. C. J. King's "Evening Light" (8) is a very pretty gentle landscape. "Declining Day" (50), by H. B. Smith, a low shore scene, with a few boats "high and dry," and a very pictorial sky, is excellent work. E. Seymour is successful in giving sunshine sparkling effect off ferns and through the woodland in "Bracken" (31).

Portraiture, still life, fruit, flowers, and interior figure subjects form Class B (Open), of nearly forty entries, varied both in subject and in quality, but on the whole creditable. J. E. Latham's "The Last Furrow" (55) is a ploughing scene, in which are two oxen and two men, but all parts of the print are so utterly diffused as to be a far from enjoyable whole. And the somewhat violent perspective of the furrows, with a great space of foreground, unrelieved in any way, makes not for peace. Of course, in a class of such wide variety of subjects it is necessarily difficult to allocate merit, and a higher place might have been given for some of the flower work. E. Seymour has a bronze medal for "Roses" (54), which, from its splendid qualities of roundness, grace, and good technique, might well have had premier position, if it is not excelled, as we are inclined to think it is, slightly, by the same exhibitor's "Cherry Blossom" (53), a very beautiful example of flower photography. Ethel H. Petty has secured a bronze medal for "Portrait of a Child" (46), but we cannot quite follow the judges here, where there was so fine an example of portrait or figure work near by in Arthur Marshall's "My Little Dutch" (49), a very delightfully thought-out and excellent piece of work. James Dunlop's "Simplicity" (262) was also awarded a bronze medal. This is a very charming study of a child, full of softness, and good half-tone. A. W. Walburn's "My Geranium" (58) is a very interesting example of flower and foliage photography, and has won a certificate. Arthur Marshall may be complimented upon his "A Study" (38), a girl-figure bending over, towards the observer, with a flower in her hand. John Smith's "A Veteran" (59), a portrait-study of striking character, shows a fine eye for a subject; but the lighting, or, may be, some after cause, is too pronounced, having the effect of being reflected from a much more polished surface than the rugged face of the veteran is likely to have been. D. W. Kyle's "Chrysanthemums" (64) are very fine, both in arrangement and by reason of first-class photographic excellence.

Open-air figure subjects, animals, etc., form Class C (Open). This is also about thirty strong, and there are many excellent things in it, showing how wide the scope of the class is under such a definition. Easily first, with silver medal, is Arthur Marshall's "The Prie-Dieu" (81), coming under the definition of outdoor by reason of the composition, a girl at devotion at the foot of a shrine of Madonna and Child by the roadside; in the devotee a fine sense of the spirit of the title, with subdued surroundings, and the whole in a frame also quite in accord with the spirit of the theme. Our heartiest congratulations for so clever and so good a piece of work. It is curious to observe that as the judges awarded no bronze medals, they may be considered to have assumed there is a gap between first and second place. While this is so, in a sense, yet the next in merit, or one of them, might well have had a better distinction than a certificate. S. G. Kimber's "The Pegseller" (73), certificate, a nomad with clothes' pegs to sell, rendered without stiffness, has yet not so much pictorial quality as Graystone Bird's "Meadowsweet" (96), a lady plucking these blossoms in picturesque surroundings, a well thought out thing, and, photographically, of very good quality.

Alexander G. Gibson has some very fine bird studies—sea-birds in all sorts of combinations, mostly with some pictorial quality, and all good as studies for those interested in such subjects from the natural history point of view, or as painters. He is deservedly awarded a certificate for "Gulls Fighting in Mid-Air" (86), a very happy snap. Other of his contributions are "Pair of Black Back Gulls" (69), "Bird Study," gull (87), and "Razorbill" (93), and all of good quality. John Smith deserves praise for his good portraiture in "A Toilet of the Deep" (78), and for the happy and natural pose of two fishermen in "A Good Yarn" (85); the technical qualities of both pictures being high-class.

Architecture, pictorially treated, exterior and interior, is dealt with in Class D (Open). The class numbers about twenty, and while it has some good things in it, equal in the order to other things which have won a silver medal, no distinction superior to a bronze medal has been awarded, such a medal being secured by S. G. Kimber for his "The Monk's Entrance" (103), a very beautiful old doorway, through which, beyond, is seen the sunlight upon a distant part of the grounds. There is charming light and shade, and fine technical excellence in the rendering of the grain and character of the architecture, without undue sharpness and detail. The same worker has a certificate for "The House of Prayer" (105), an interior, rendered with great softness and delicacy. Arthur Marshall is represented by "The Arcade" (99), apparently a covered way in an old German town, and "The Chapel, Haddon" (100), the main factors of which are the font and the relieving column, near by, the work in which is of the highest excellence, and we think deserving of recognition. "There is a little gem, by Harold Burkinshaw, "The Castle Gateway" (104), in which there is technique of the best in the rendering of detail, shade, and sunlight. The selection, too, is admirably pictorial and good. Percival W. Crane's "Crypt de l'Aquilon, Mont St. Michel" (108), is worthy of praise, and for the admirable way in which the detail in the darks has been softly handled.

Lantern slides (open) have been brought together in Class E, and prove to be of excellent quality and variety. F. J. Mortimer has a number of his splendid wave studies, Graystone Bird is represented in variety, while Alfred Bedding is represented by good architectural studies. The awards are: Silver medals, F. J. Mortimer, two (251, 292); Graystone Bird (293); and Dr. Geo. H. Rodman, two (295, 296). Bronze medal, F. G. Tryhorn. Dr. Rodman's slides are some exquisite beautiful studies of the interior, and exterior, of shells by radiography.

A silver cup, given by Mr. J. Kinton Bond, Head-Master of Plymouth Corporation Grammar School, is secured by Arthur Marshall, for the best average work in not less than three classes.

Landscape, seascape, and river scenery are grouped in Class F (Members), and a very creditable display is brought together, about seventy frames. Silver medals are awarded to C. H. Dymond for "Early Morning, Polperro" (125), a study of old houses, some figures, the low-tide harbour, boats, and the etceteras that go to make up the pictorial elements of an old Cornish fishing place, with the distant high ground of the adjacent country, making together a very artistic combination and arrangement skilfully worked out, and "A Golden Evening, Polperro" (128), a totally different kind of theme—the harbour, with the tide in, the fishing boats at their moorings, and the glow of the evening light on the houses of the quaint old town. The work is good, but perhaps the rendering rather lacks softness and tenderness. A silver medal is also secured by Wm. Clayden for "A Gleam of Light" (132), for a very nice pictorially rendered view of a fleet of fishing boats, under an evening sky, with a soft, oily sea as foreground, upon which is reflected the gleam of light in the sky overhead perhaps just a trifle too strongly for the balance of the subject. The whole is, however, a highly creditable example of good selection and excellent technique. C. H. Dymond's "A Rainy Day on the Tavy" (135), the attempt of giving the effect of rain in the neighbourhood of a Dartmoor river, with its great grey boulders, and its rushing waters, is fairly successful, and has been awarded a bronze medal. J. Trouern Trend has secured a like distinction for his "Soft Silvery Mists Veil the Distance" (156), which is a rather clever rendering of the soft grey effect the title suggests, the look through the trees being admirably done. He contributes a number of good things in the class, and among them may be cited "Ever and Anon a Shadow Steals Swiftly By" (156), and "Amidst Sunshine and Shade" (142) two charming studies of Old Cockington, and "A Tit Bit on

the Tamar," a peep out and downward upon that river from the umbrageous woods that clothe its high banks. "Afon Arthog" (117), by D. Tudor Davies, a study of Welsh moorland or mountain country, is interesting, and has received a certificate. "The Rock of the Sea," by C. H. Dymond, has a certificate; it (119) is, of course, a "pictorial" title, for it has not yet become possible to photograph the roar of anything, but as a picture of a very fine, swirling, dashing, and tumbling sea, this is a very good bit of work. J. T. Johnson is the winner of a similar distinction for his "Watersmeet, Lyme Mouth" (120), a scene on the River Lyn, in North Devon, a very beautiful spot, and of interest to many for its place in the story of "Lorna Doone." This is an excellent bit of photography. Maton's "Home of the Moorhen, Summer" (118), is a very charming picture of river and of adjacent woodlands. A. W. Hicks' "Breakers, Trebarwith" (133), a scene on the wild coast of North Cornwall, is deserving of commendation. "Nature's Mirror" (149), A. B. Fellowes Prynn, is a very clever rendering of a reflection, in which a group of pines set picturesquely on high ground give so reflections in the pool below. "A Welsh Landscape" (162), Fredk. Johnson, gives a good idea of expanse and distance, though somewhat grey and sad in tone. A. W. Hicks' "An Apple Orchard" (171) is a very good attempt at rendering a difficult subject.

Portraiture, still life, fruit, flowers, and interior figure subjects form the details of Class G (Members). It is of moderate dimensions but of good average quality. The silver medal goes to Albert K. Coleman, for "The Dinner Hour—a Yarn" (195), a study of three figures at a table, an interior, apparently a mill, or workshop, of some sort, somewhat dimly lit, rendered with a soft and agreeable texture and quality. The figures seem just a trifle posed, but this may be accounted for possibly in the fact that the exposure could not have been instantaneous. The arrangement is good, and the result creditable. Bronze medals go to Wm. Clayden for "A Portrait Study" (184), of moderate quality, and to C. H. Dymond for "Portrait of a Lady" (195), of good technique. Certificates are awarded to A. E. Coleman for "In Olden Times, Dressing Millstones" (188), not unworthy second to his silver medalled picture, and interesting too, as showing something that will, ere many years, obtain no longer; and "Drawing the Harvest Cider" (194), by W. C. Johnson, a good bit of work, considering that the light in the dim cider store must have been poor. F. C. Bowlett's "Cutting Spokes" (198) depicts an old workman engaged in the prosaic work of making spokes for cart and other wheels, and the idea of the photographer has been very creditably carried out.

Open-air figure subjects, animals, etc., form Class H (Members) of nearly thirty entries. A silver medal is awarded to C. H. Dymond (who also takes a silver plaque, presented by Mr. J. T. Johnson, vice-president, for the best work in not less than three classes) for "An Anxious Moment" (216), a very clever bit of genre work. A group of boys are watching one who is about to make a "shot" in a game of marbles. They are very capably arranged, and the composition is excellent; all the boys look natural and interested in the game, and the result is good in every way. The surroundings help, and there is nothing but praise for the photographer's work. Certificates have been secured by A. S. Adams for "The Reapers" (220), a harvest scene, in which a reaping machine, horses, and men play qualifying parts; "A Gamp for Two" (222), two lads under one umbrella, by the same worker; and Wm. Clayden, "Repairing the Sail" (230), an incident associated with a fishing vessel, the details of which is the scene, but the many details necessarily included in the subject—because the eye of the camera saw them—were somewhat distracting. "On the Road to the Fair" (231), by F. C. Bowlett, a flock of sheep being driven towards the onlooker, is rather good. Wm. Clayden's "Moorland Ponies" (204) has much pictorial quality, and his "Oh, What Fun" (205), children swinging on a gate, deserves a word of praise.

Architecture, pictorially treated, exterior and interior, make up Class I (Members), which is a small class. Certificates were awarded to E. G. Turney for "Crypt, Hereford Cathedral" (233), a well selected subject, of good technique; and J. T. Johnson's "The Old House at Home" (234), a country thatched cottage, of no particular or striking character, but somewhat picturesque. Fredk. Johnson's "Haddon Hall" is soft and agreeable. J. T. Trend's "A Bit of Tintern Abbey" (257) is praiseworthy. "Old Boringdon" (238), an ancient manor house in South Devon, by A. B. Fellowes Prynn,

ht well have had official recognition, as it is good photography, and excellent technique, as well as being pictorially acceptable; the same maker's "Old Gateway, Tewkesbury" (243), has excellence and good dity.

lantern slides are included in Class J (Members), and form a ditable display. Silver medals are awarded to C. H. Dymond a varied collection (304), and to Fredk. Johnson, also for sub- s in variety (313). A bronze medal is secured by Wm. Clayden a very nice set, several of which are duplicates of his pictures the walls (306). Certificates went to F. C. Bowtell (308), F. nson (314), and J. T. Johnson, two (315 and 316).

fr. Baragwanath King, of Plymouth, offered a special medal for best rendering of an after-glow; this formed Class L (Members). frames were under a score, but they were all more or less "sun- y." The medal was awarded to "After-Glow, Isle of Wight" 4), by Fredk. Johnson, in which he had secured, as far as was sible in photography, the rendering of the after-glow, and the ecess of the whole had been greatly helped by printing on a suit- y tinted paper. Other creditable examples were by C. H. Dymond J. T. Johnson.

FORTHCOMING EXHIBITIONS.

May 24-28.—Devonport Camera Club. Hon. Secretary, A. J. ford, 78, Charlotte Street, Devonport.

June 12-24.—First International Salon in The Hague. Sekretariat ng, Conrad Kade 63, The Hague, Netherlands.

June-October.—Glasgow Photographic Exhibition. Secretary, Art lery and Museum, Kelvingrove, Glasgow.

July 14 to September 30.—Vienna Photographic Society. Secretary, Burger, Karmelitergasse 7, Vienna 11.

August 1.—Andover and District Horticultural Society. Photo- phic Section. Hon. Secretary, W. L. Gradidge, Jubilee House, Dover.

October 1-30.—Berlin International Photographic Exposition. M. anz Goercke, Berlin W. 62, Maassen-Strasse 32, Germany.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., nes Dunlop, Myrtlebank, Motherwell.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 23-26.—Hove Camera Club. Hon. Secretary, A. R. egeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., W. Simmers, Aberdeen House, Ramsgate.

December 2-8.—Southsea Photographic Society. Hon. Secretary, J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. retary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, st 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. retary, W. Barrowman, Ayr View, Muirkirk.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. umber, Oakdene, Highfield, Southampton.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. ott, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

May 31.—Ensign-Vidil. £100 in prizes for negatives on Ensign- d films. Houghtons, Limited, 88-89, High Holborn, London, W.C.

June 30.—"Photographic News" Quarterly. Money prizes, silver d bronze medals for prints. Any subject. "Photographic News," Cecil Court, Charing Cross Road, London, W.C.

June 30.—Kodak. £1,000 in cash prizes for pictures taken on dak films and plates, etc. Kodak, Limited, 41-43, Clerkenwell ad, London, E.C.

October 1.—Thornton-Pickard. £100 cash prizes for pictures taken th Thornton-Pickard cameras and shutters. Thornton-Pickard nufacturing Co., Altrincham.

October 10.—Luna paper. £240 cash prizes for prints on Luna paper. cien Allegre and Co., 59a, New Oxford Street, London, W.C.

October 15.—Belgian Association Lantern Slide Stereogram Com- ition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, ussels.

October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 15, 1905.—Ilford. £750 in prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

Studio Gossip.

A BIT of Human Nature.—No business requires a deeper study of human nature than that of the professional photographer, and human nature is much the same the world over. He must bear in mind that a large proportion of his work is of ladies and children. There are few cases in history where the lady does not sit, in the best gown she owns, whether rich or poor, and likewise her child or baby. She wants the gown reproduced, and, often in the case of the society and professional woman, she sits more for the gown and the fit and hang of it than for any particular expression or lighting of her face. If there is a particular weave or texture of lace or fabric which conveys the idea of expere, she desires it to show for what it is. Detail cannot then be overlooked, and a printing process that secures every detail and half-tone of the negative is important. In this particular carbon and Aristo platino excel over platinum and all other processes. All there is in the negative you find in the print.

ADVICE to Members of the P.P.A.—Members are reminded that their obligations to the association, says the "Handbook of the P.P.A.," do not consist simply in paying their subscriptions and electing a committee to carry on the work on their behalf. They should take an active part in strengthening the position of the association by inducing as many as possible of their brethren in the profession to join, and particularly by endeavouring to promote a friendly feeling amongst those who are engaged in business in their own localities. Photographers should not war against one another, but should devote their belligerent energies to warring against their common enemies. That their community is subject to such successful attacks from those outside is due, mainly, to their want of unity. It is impossible to do away with competition—indeed, competition on legitimate lines is beneficial rather than otherwise; but competition carried on on the petty lines of price cutting and taking mean advantages of one's fellows injures all alike, and most of all those who resort to such practices.

THE Austin-Edwards Monthly Film Negative Competition.—The prize camera for the current month has been awarded to Miss D. Dillon, 15, Westbourne Gardens, Folkestone, for her negative, "Basket of Apples."

MESSRS. CASSELL AND CO., LTD., announce the publication of a new work on photography, in monthly parts, price 7d. net, entitled "The Book of Photography: Practical, Theoretic, and Applied." It will be edited by Mr. Paul N. Hasluck, and Part I. will be ready on May 27.

THE Health Resorts Development Association have sent us a copy of the Southport Corporation Guide. It forms one of an excellent series of well illustrated guides to various popular health resorts. It is very complete, and full of information concerning the district, and should prove of use to the visitor who is also a photographer. A copy will be forwarded free by sending a postcard request to the Town Clerk.

WE have received a copy of the Great Eastern Railway Company's freshly illustrated "Tourist Guide to the Continent," published at the price of sixpence. Among its new features are particulars of new tours in the Tyrol, in North Germany, and in Norway, Denmark, and Sweden, via the Royal mail Harwich, Hook of Holland, route; of tours in the Luther Country, and Thuringian and Hartz Mountains; with a series of Continental maps, and a chapter, "Dull, Useful Information," giving particulars of the cost of Continental travel.

Patent News.

The following applications for patents were made between May 2 and May 7, 1904:—

Packing Films or Plates.—No. 10,097. "New and improved method of packing sensitive cut films or plates, and the manner of exposing same in the camera." George Wishart.

Cameras.—No. 10,340. "Improvements in and relating to photographic cameras." Nicholas Wladimiroff.

Shutters.—No. 10,566. "Improvements in, or relating to photographic shutters." Alfred Bult Allen.

Enlarging Apparatus.—No. 10,568. "Improvements in and relating to photographic enlarging apparatus." Complete specification. William Charles Hughes.

DEATH OF M. MAREY

THE Paris correspondent of the "Times" announces the death, at the age of 74, of Professor Etienne Jules Marey, the master of that method of experimental physiology by which, together with Claude Bernard, he enriched this science with numerous discoveries. He was, if not the virtual inventor, at all events the perfecter of the system of graphics for the measurements of physiological phenomena; the deviser of the sphygmograph for the notation of the pulse and heart beats and respiratory movements; the analyst by means of instantaneous photographs of movements of human and animal locomotion, the flight of birds, the galloping of horses, etc., becoming thus an initiator of the cinematograph. But these inventions are only the more striking devices with which he ingeniously opened up surer methods of research in physiology. The mechanical appliances which he conceived figure to-day in every physiological laboratory in the world. One of the most amiable of men, few deaths will be more keenly felt in the scientific world in France. He was a Burgundian from Beaune, but since 1869 had been a Parisian and a familiar figure in the precincts of the Collège de France.

A TIBETAN Stamp.—Mr. D. Field writes from 4 and 5, Royal Arcade, Old Bond Street, on May 10. "I have pleasure in enclosing a photograph of a Tibetan stamp which was recently presented to me by Mr. G. Lindsay Johnson. Such is the secrecy of the Tibetans with regard to all their affairs that the fact that they have a postal system with properly authorised Government stamps has only just leaked out. As will be seen, the stamp is a most primitive affair, being merely a native character impressed in red sealing wax. According to a missionary friend of Mr. Johnson's, who sent him the stamp, when it is required to post a letter in Tibet the sender takes it to the nearest official post office and pays the amount due for the postage. After this formality the letter is impressed with this seal, and it is then considered properly posted, and is forwarded to its destination; but letters not bearing the seal do not receive this polite attention."

THE members of the Hull Society turned up again in great force last Saturday, the destination being West Ella. It is interesting to note that they arrived by train, cycle, trap, motor, and last, but not least, by foot. A storm came on at starting time, but nevertheless, this did not prevent the enthusiasts finishing their journey, who were certainly well repaid for their struggle, because it cleared off later on, and proved an ideal and agreeable time. The subjects were varied, and should prove profitable if carefully treated. Several lady friends were very much in demand as studies, and placed in various positions with a view to securing pictures of more than ordinary merit. Some exercised their patience upon sheep and lamb studies, trying all they knew to find pleasing and effective grouping. It is intended to provide sunbaskets, etc., at several of the forthcoming outings, and thus supply the members with further material for landscape with figure study subjects. This means much interest, and an additional attraction, likely to be highly appreciated. The Society next visit Howden, May 28, leaving Cannon Street station, Hull and Barnsley Railway, at 1.25 p.m., when further special features and arrangements are to be made.

New Apparatus, &c.

The "Syntor" Double Anastigmat. Series 1D., made by C. P. Goerz 1-6, Holborn Circus, London, E.C.

This lens being particularly intended for use on hand cameras, only obtainable in foci varying from $4\frac{1}{2}$ in. to $8\frac{1}{2}$ in. The Syntor F appears to be well corrected for chromatic and spherical aberration and for astigmatism. The angle covered at F6.8 is 64° , but by use of smaller stops this angle can be increased to 70° . A plate having a base line equal to the focal length of the Syntor used excellently covered, and definition is good to the edges of the circle given. Where a considerable displacement of the lens from the centre

is desired, the next longer focus is recommended. The Syntor Double Anastigmat F6.8 can also be used with advantage as the positive in telephoto lens system, and its back combination when used with small stop, becomes a serviceable single lens of about double the focus of the complete lens. The Goerz Syntor F6.8 will be seen, therefore, to have all the properties expected in a modern anastigmat although less in price than some of the old type of rapid rectilinear lenses.

Warwick "Special Rapid" and "Double Instantaneous" Dry Plate. Made by the Warwick Dry Plate Company, Warwick.

The speed of these well-known brands of plates has now been greatly increased, and while still retaining their characteristics of freedom from fog, density, fineness of grain, and latitude in exposure there can be no doubt that the marked increase of speed in the latest batches will be much appreciated, especially for indoor work and snapshot out-door exposures under bad and medium light conditions. The plates we have tried appear to be thickly coated with emulsion rich in silver, in an extremely fine state of division. Test exposure on a sunlit street scene, using a focal plane shutter working at 1-800 sec. and lens stopped down to $f/11$, gave, with quick development, negatives full of shadow detail, and of excellent printing quality. The plates also appear to be able to stand a considerable amount of forcing in development without fogging or frilling, and speed has apparently not been secured at the sacrifice of the many other essentials to good negative. Formulæ for use with the plates are enclosed with each box. The prices of the plates remain the same.

New Productions of Cadett and Neall, Limited, Ashted, Surrey.

Dagas Paper.—This is a gaslight printing paper, and is made in three grades of surface, matte, medium matte, and glossy. It is paper for contact printing by artificial light, and can be manipulated developed, and fixed in ordinary gaslight or subdued daylight, according to the directions enclosed in the packets. Great brilliancy and excellent gradation quality are their special characteristics. The speed has been very carefully graded for the greatest convenience of users, and a special feature will be found to be the superiority of the colour of the images on Dagas paper, the unpleasant greenish colour so often produced by other makes being absent.

Dagas Postcards.—These have similar qualities, but are made with one surface only, smooth matte.

Bromide Postcards.—For rapid artificial light printing and development in the dark room these postcards will be found to be very brilliant and clean. A fine sepia tone can be obtained by the use of one of the formulæ enclosed in the packets.

Self-Toning Postcards.—The simplicity of the manipulation, together with the excellent surface of prints upon these self-toning postcards will, we think ensure much popularity for the brand. A great variety of pleasing tones may be obtained, and no effort appears to have been spared to make the product of first-class quality.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Day.	Name of Society.	Subject.
28	Kodak Exhibition.....	The Drill Hall, Wolverhampton.
.....	Nelson Photographic Society	Print Evening.
.....	North Middlesex Photo. Soc.	<i>Intensification and Reduction.</i> Mr. H. W. Bennett.
.....	Cricklewood Photo. Society.....	<i>Technical Control for Pictorial Results.</i>
.....	London and Prov. Photo. Asso.	<i>Factorial Development.</i> Mr. W. T. Wilkinson.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

MEMBERS' meeting was held at the Royal Photographic Society, Russell-square, on Friday, the 13th inst., at 8 p.m., Mr. Alfred Ellis, President, in the chair.

The Committee's report of the progress of the Association since the last meeting was presented, and adopted.

The President intimated to the members that the Committee had been considering the abandonment of the annual dinner as a regular feature. Their first annual dinner had an attendance of about 100. The second fifty-two, while this year the number had decreased to forty-nine. Of course, if it was desired to hold such a meeting the request of a good number of the members, the Committee could be pleased to arrange accordingly. With regard to the annual general meeting, it was found that the holding of it in October, immediately after the holidays, was an inconvenient time of the year, as practically no meeting had been held between June and October. Therefore, if the dinner fixture in March was abandoned, it was thought it would be better to hold the annual general meeting in that month, and to bring under notice what has happened during the busy part of the season.

The matter would, however, be settled when considering the alteration of rules at the next general committee meeting.

The President, in introducing the subject for discussion that evening, viz., "Professional Photographers' Price Lists and the Avoidance of Inconsistencies in Them," said that on two occasions recently the Association had been asked to assess the value of photographs, and examining the price lists of the photographers concerned and those of other photographers who were in one case in the same town, at difficulty had arisen in arriving at the proper proportionate valuation of the different photographs and the cost of the taking of these photographs. On examination of the price lists of several different firms the conclusion arrived at was that most of them had been compiled without proper consideration of the relative value of the different kinds of photographs, and without reference to the value of the taking and of the additional copies supplied at certain prices.

Mr. Mackie brought forward several examples of the inconsistencies of price lists. He said one noticeable point was that there was not a general understanding as to the particular size of picture referred by a particular name; for instance, he had found the term "studio" portrait, which he believed was usually intended to denote a picture taken on a whole plate and trimmed to about 8 by 5, and in one or two cases to so describe a picture taken on a larger plate, the price list gave the size as 11 by 8. He noticed too a tendency to employ ambiguous terms for the printing process, such as "silvertype," which would mean anything looking through a number of price lists he found many cases in which, if one went to work artfully, photographs could be obtained cheaper than it was intended they should be supplied. For instance, one case he found cabinets quoted at 18s. 6d. per dozen, six for 6d., extra copies twelve for 12s., six for 7s. 6d., so that if twelve were ordered first and then six extra copies afterwards, 25s. would be paid.

The President said that in bringing this subject under notice that evening he had in view two recent and various other cases which have been brought to the notice of the Association, and also happened up in his own business and that of others. He thought great care should be given to the basis upon which prices were quoted. For instance, you have a sitter who, unfortunately, does not pay you at the time of sitting, and subsequently a dispute

arises. It may be a schoolboy is photographed, and on the proofs being submitted the parents are not satisfied. Meantime, the boy has returned to school and cannot be re-taken. You suggest that he sit again when he returns from school, but the parents object, on the plea that the boy will be older, and make other excuses. They therefore ask you to charge for what has been done and for the proofs, and allow for the copies not had. Now, the price charged by some people for extra copies, deducted from the price charged per dozen, would not be sufficient to pay a photographer for the sitting, developing, retouching, etc. He was of opinion that a price should be fixed for the taking of a negative and for the proofs submitted, and then so much for the additional copies, so that it tallies with the extra copies rate. He thought that if worked out on that basis trouble would be obviated.

Mr. Mackie instanced a recent case of claim against a railway company for broken negatives, in which the photographer claimed for the whole amount of his order. He could, of course, not charge for the prints he had not produced, and it was a question what was the value of the negative. By Mr. Ellis's system no difficulty would arise.

Mr. Fry brought forward a suggestion to promote some branch or association in which assistants could join. Mr. Ellis thought some expression of a requirement of this kind should emanate from the assistants themselves in the first place, and in view of the amount of work on hand it would be advisable to complete it before touching fresh ventures. In any case, it would be well to consider the matter in committee.

Previous to the members' meeting a general committee meeting was held, at which the following were present:—Messrs. H. A. Chapman, J.P. (Swansea), Alfred Ellis, A. Mackie, F. A. Bridge, Wm. Grove, S. H. Fry, E. Scamell, Lang Sims, and H. C. Spink (Brighton). Mr. Alfred Ellis, President, in the chair.

Letters of apology for non-attendance were read from Messrs. Martin Jaconette and W. Gill (Colchester).

Letters to and from Mr. Louis Langfier, in reference to his resignation from the Committee, were read. It was thereupon decided to accept Mr. Langfier's resignation, with an expression of regret at the loss of his valuable services.

The draft of the report for the members' meeting was read and passed.

The names of those gentlemen who had expressed their intention of exhibiting at Derby were read. It was decided that they should be published.

The Committee then considered certain alterations in the rules, which it is proposed shall be presented to the annual general meeting in October.

REPORT OF THE COMMITTEE.

Since the last members' meeting in February the members have had an opportunity of gathering together at the annual dinner, which was held, according to the rules, on Friday, March 11. Forty-nine members and guests were present, and the opportunity of the occasion was taken to present the President, Mr. Alfred Ellis, and the two past Presidents, Messrs. Thomas Bedding and William Grove, with a gold token or souvenir of his year of office, subscribed for by the members of the Committee.

An invitation has been issued to each member to send specimens of his work to the exhibition of professional photography, to be held under the auspices of the Association and of the Photographic Convention of the United Kingdom to be held at Derby in June and July. The privilege has not been accepted by a large number of members, but as far as can be ascertained up to the present the number of exhibitors will be about twenty-four, and the list includes the names of many of the best and most representative photographers in the country. Messrs. W. Crooke and Fred Hollyer have consented to contribute their pictures in an exhibition at the rooms of the Royal Photographic Society.

The Committee have been devoting a great deal of time to the consideration of the granting of certificates to Associates, and the task of providing means of overcoming the obstacles to the successful working of a system which will be satisfactory from an employer's point of view is a long and difficult one. Considerable progress, however, has been made, and it is hoped shortly to issue a prospectus of that part of the scheme which provides for the granting of certificates without examination to assistants who can prove competency by the testimony of past and present employers.

The Committee regret that they are losing the services of Mr. Louis Langfier, who has resigned his seat on account of inability to spare the time for the duties.

The Committee are pleased to notice that the local branches at Edinburgh, Hull, and Liverpool are holding regular meetings. Their discussions are duly published from time to time in the *BRITISH JOURNAL OF PHOTOGRAPHY*.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.— LIVERPOOL BRANCH.

APRIL 29, 1904.—Present: Messrs. G. Watmough-Webster (chairman), W. T. Smith, H. Dowden, O. Looser, R. Waile, E. Vanderbilt, A. Priestly, A. F. Mowll, W. Warrington (Hon. Sec.).

The Chairman said with regard to suggestions for preventing sitters making unfair use of proofs, he had received a letter from a photographer, not a member of the Branch, giving particulars of his way of treating proofs, which had proved successful.

A proof so treated was kindly sent with the letter, and was passed round among the members, who voted it an excellent idea.

The question of cutting prices was brought before the meeting by a member who thought some effort ought to be made against it, particularly in such cases as might exist among members of the P.P.A. He thought there were such cases. The discussion that followed was long and interesting. Several members had suffered, directly or indirectly, from the proximity of the "Cheap Jack," and the various experiences that were related showed the difficulty of dealing with the question. To give publicity to the methods of the offenders, to point out the often irresponsible—even unscrupulous—characters of very many of them was felt to be desirable and a step in the right direction. Two cases out of many, of members' own personal experiences, were typical of the class of man who cuts prices to a ridiculous point to attract business. One, of a man who opened "opposite" a member in a building consisting of offices, etc., and offered three cabinets and a 12 in. by 10 in. enlargement for 2s. 6d. He flourished for a time; then one day, having business in an office in said building, the member in question went across and found the staircase crowded with people looking for the photographer, who had flown. He left behind a notice to say he was returning shortly, a large number of paid-up but unfulfilled orders, and much strong feeling. Another case brought forward showed even more unscrupulous principles. A studio opened, prices almost impossibly low, a roaring business for two weeks, then a missing photographer (save the mark!). He left word he had gone to South Africa—which was about all he did leave—for an examination of the premises indicated that he had not thought it necessary to expose any plates or do any work, except take the money.

The question of the dealer's share of the responsibility in the matter was talked over at considerable length, but the members were not unanimous in their opinions of the extent to which good terms from dealers enabled cheap men to carry on.

The subject was adjourned to the next meeting.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 12th.—Mr. A. J. Brown in the chair. Mr. Brigginslaw, one of the founders of the association, was welcomed, and congratulated the association upon its continued vitality; its records in the *BRITISH JOURNAL OF PHOTOGRAPHY* were always enjoyed.

Mr. Drage asked the opinion of the members upon the system of the Dry Adhesive Company, whose method was shown at the previous meeting.

Mr. Furley Lewis was quite pleased with the system, as a time saver and for convenience.

Mr. Rapson pointed out the many branches that could be worked, plate marks to suit the picture, tints to suit and fit the prints, freedom from the distortion met with in prints mounted wet, prints could be mounted upon any substance, thin or thick.

CAMERA CLUB.

If Theodore Hook, or any other of that merry band of a bygone generation, whose delight it was to play practical jokes, could have peeped into the Camera Club on the evening of the 9th inst., he would have been sorely tempted to seek the aid of the police in order to play a prank upon the members. And if the police had been so

summoned they would have witnessed an unwonted sight, and which would have gone far to support the notion that the King's peace was being seriously threatened. Two men stripped to their shirts and engaged in hot conflict with the deadliest looking rapiers. They were both well-skilled in the use of their weapons even at a glance, for they thrust and parried with suchadroitness that it was impossible to analyse the movements—it was a series of flashes of clashing steel. Whilst these two were thus intent upon their deadly work, the members of the club stood and watched the conflict with the greatest interest, and seemed to hang upon the result as if it had been a matter of personal concern. But it was not in reality a deadly fight, although it looked like one. The truth was that Mr. Egerton Castle was giving a lecture upon "The Romance of Swordsmanship," and he had brought with him his fencing master, and this was one of the many illustrations showing how certain kinds of weapons were used. The discourse had nothing to do with photography, that it may be regarded as one of those extra subjects with which the Camera Club occasionally seeks relaxation from "the usual round, the common task."

FRANKLIN INSTITUTE (PHILADELPHIA).—SECTION OF PHOTOGRAPHY AND MICROSCOPY.

APRIL 7.—Dr. Henry Leffmann in the chair. The chairman called attention to several exhibits which were of more than usual interest. The first of these consisted of several specimens of the "Parall. Stereograms" of Mr. Fred. E. Ives. This optical device was originally exhibited several years ago at one of this section's meetings, but has since been improved, and is now being commercially exploited. The second exhibit consisted of specimens of photographs in natural colour of natural objects and of paintings made by a photographic process devised by Messrs. M. Miley and Sons, of Lexington, Va. The resulting photographic prints exhibited surprisingly close approximation to the colouring of the originals and were much admired. The regular communication of the evening, "Microscopic Studies with the Moving Picture Camera," was a highly interesting demonstration, showing many minute living organisms, etc., that had been magnified many times by the microscope and then photographed by the method used in making moving pictures. Among a number of subjects thus exhibited the circulation of blood in the web of the frog's foot, and the circulation of cell fluid in living waterweed, are specially worthy of notice. The exhibits were explained and commented on by the chairman, and, at the close of the meeting, the thanks of the meeting were tendered to Mr. S. Lubin, of Philadelphia, who supplied the material and moving-picture camera for making the demonstration.

CROYDON CAMERA CLUB.

MAY 11th.—The capabilities and merits of Venus paper were demonstrated by Mr. W. H. Rogers before his fellow members. It is claimed for the paper that it possesses certain advantages over gelatine mat papers. It does not blister or frill, always remains flat, warm water may be used for washing, and heat for drying, toning is easy and uniform, and the final results are unlike the "ordinary photograph," which may inferentially seem to be rather an unkind reflection on the "ordinary photograph." Rough, smooth, and canvas grained paper can be obtained and sensitised materials. Mr. Rogers, although his acquaintance with the paper and its working was of the slightest, found no difficulty in its manipulation, and some pleasing prints were toned and fixed and passed round for inspection. A statement by the makers, as to the advantage to be gained by printing weak negatives in a dull light, led to a general discussion on the Bunsen Roscoe Law and whether it held true for printing processes in general. Mr. E. A. Salt said he always thought it broke down with P.O.P., but an inspection of a set of prints sent him by Mr. Alfred Watkins printed in the sun and shade showed no apparent difference. He had been informed the law had been found true for albuminised paper. Mr. Hugh Allen said it certainly did not apply to the gum bichromate process, the question of the intensity of the light apart from the "time" factor was then of the greatest importance, and as regarded P.O.P. in a home-made print meter, constructed out of numbered layers of tissue paper, when the light became feeble the piece of P.O.P. continued darkening in the lower numbers without any perceptible alteration in the higher. Mr. Sellors thought the law also did not apply to carbon, with its thick film of pigment.

During the evening the Watkins new print meter was passed round and inspected with interest. A portion of a sensitive disc of paper seen through a small circular aperture, which it partly fills; by applying pressure to the front and back of the case, the paper is made revolve in front of a series of standard tints, approximately in geometrical progression. The range 1 to 32 is wide. By rotating the disk a fresh surface of paper is exposed. It was generally thought that the meter was of ingenious construction, and would prove useful to carbon workers. The president, Mr. S. H. Wratten, in proposing a vote of thanks to Mr. Rogers, said the Venus papers undoubtedly held a place, and had stood the test of time, and alluding to the discussion which had arisen, suggested that members might make some comparative experiments and report results.

CENTRAL PHOTOGRAPHIC SOCIETY.

Saturday, the 7th inst., the above society opened their summer programme with an excursion to Roehampton and Wimbledon Common. In spite of the threatening weather, a muster of eleven was obtained, and a start was made from Waterloo Station by 2.35. Under the leadership of Mr. T. Holland the party made their way to Roehampton, and after a little skirmishing quickly settled down to work. A visit was made to the windmill, after which the party adjourned, at the invitation of the leader, to his house to tea, and there spent the evening. The outing was voted a great success by all participating in it. The next excursion of the society will be on May 28th, when Mr. F. R. Rose will conduct a party to Mill Hill and Stanmore. Mr. W. Hobday, the secretary of the Central Photographic Society, at Peter Hall, Strand, W.C., will be pleased to answer any inquiries and to forward programme for 1904 on hearing from those interested.

New Zealand Tourist Photographic Department.—The "New Zealand Times" states that 11,000 photographs illustrative of New Zealand scenery and life were sent to various parts of the world last year by the Tourist Department.

The first of the Royal Society's two annual conversazioni was held in the Society's rooms in Burlington House on Friday last. The president, Sir William Huggins, received the members and guests. The exhibits were, as usual, numerous and varied, illustrating the results of the most recent research in certain departments of science. Museum exhibits were conspicuously absent, except in one instance, where they are being reserved for the ladies' soiree next month. Apart from these there were many exhibits calculated in the main to appeal only to the specialist, though a few could without doubt be appreciated by the mere intelligent onlooker. Sir William Abney showed a beautiful arrangement by which colour photographs are shown by the substitution of spectrum colours of the glasses, with the result that the colours on the screen are much truer and purer. Some of the results were quite striking. Another interesting arrangement was that of Mr. Sanger Shepherd, who exhibited examples showing the application of natural colour photography to the production of lantern slides of characteristic spectra for lecture and educational purposes. Professor Carl Pearson's exhibit was of especial interest, being a photographic study of the English skull, 1600-1850, showing some of the results of the biometric work at University College during the past five years. It is a selection from a series of photographs of English skulls, illustrating normal and abnormal types. There are two series, numbering upwards of 100 altogether, from old pits or graveyards in the City. Professor Herdman had an interesting exhibit illustrative of his recent visit to Ceylon for the purpose of inspecting the pearl oyster fisheries. His exhibit included samples of Ceylon pearl oysters at various stages of growth, specimens showing the structure of the pearl oyster, microscopic preparations showing the structure of the pearls, photographs and diagrams of the methods employed at the fisheries, and other details of the industry, while other results of Professor Herdman's visit were illustrated by a fine series of lantern slides shown in the lecture room. Dr. Alan B. Green showed some curious photographs illustrative of the radio-activity of bacteria exposed to pure radium emanation. Some of the results were very striking, and the method may lead to important results as to the real nature of the bacteria experimented with.

Commercial & Legal Intelligence

At a London Police Court on Monday last George Browning, an auxiliary postman at 12s. a week, who said he was formerly a photographer, but had lost his trade through the rise of amateur photographers, was sent to four months' imprisonment for letter stealing.

At the Central Criminal Court, on Tuesday last, William Friese-Green, forty-eight, described as an inventor and patentee, pleaded "Guilty" to counts in an indictment charging him with offences against the Debtors Act by obtaining credit without disclosing the fact that he was an undischarged bankrupt. Mr. Arthur Gill prosecuted; and Mr. Slater appeared for the defendant. In mitigation of sentence Mr. Slater said that the defendant owed his present misfortune to taking upon himself the debts of a company in which he was interested. His bankruptcy took place twelve years ago, and the defendant, in assuming the responsibility for the debts, was under the impression that in these circumstances he was not obliged to disclose the fact that he was an undischarged bankrupt. The Common Serjeant sentenced the defendant to two months' imprisonment in the second division.

At the Clerkenwell Sessions last week George Esser, 31, sailor, and John Smith, 33, coster, pleaded guilty to having committed a burglary at the premises of Sinclair and Co., Ltd., opticians and jewellers, Haymarket. The prisoners smashed a plate glass window on the early morning of the 30th of April, and stole a velvet-covered tray and charms, worth £50. Police-constable Fairclough, attracted by the noise, chased and captured Esser, and a night flusher named King pluckily detained Smith with the stolen property. Both men had been many times convicted. Esser had been in a reformatory and now had a considerable remnant to serve on a sentence of seven years' penal servitude. Smith had twice been in penal servitude. Detective-sergeant West said window smashing in the West End was greatly on the increase and of almost nightly occurrence. Esser was ordered twelve months' and Smith eighteen months' hard labour.

A COPYRIGHT ACTION FAILS.—At Swansea County Court, on Monday, before his Honour Judge Gwilym Williams, Messrs. A. and G. Taylor, photographers, of Swansea, brought an action against William Newcombe, Joseph Rosser, and Griffith Davies, trustees of the Swansea district of the Independent Order of Rechabites. Plaintiffs alleged that in February, 1903, defendants or their agents ordered of the plaintiffs' photographs of the town and district for the purposes of a book defendants contemplated publishing, and plaintiffs agreed to supply the same upon a condition that photographs and views should be used only in the book mentioned, and it was alleged that without the consent of the plaintiffs the views were published in another book issued by the defendants, and plaintiffs now claimed an injunction restraining defendants from further copying or publishing the photographs. Mr. Villiers Meager (instructed by Messrs. Pictou, Evans, and Jones) was for plaintiffs, and Dr. Williams (instructed by Mr. J. E. Rowlands) was for defendants. For plaintiffs Mr. Lambert (their Swansea manager) said he was asked to take views of Swansea for reproduction in the souvenir issued in connection with the visit of the Rechabites to Swansea last year. This order was subsequently ratified by two other members of the order named Tasker and Stevens. He took a number of photographs on the condition that after being used in the souvenir the copyright was to remain with his firm. In addition to being used in the souvenir, he found the pictures had, without his sanction, been used in a booklet issued by the Rechabites. In cross-examination he said he had no written agreement that the copyright was to remain with him. He admitted that the photographs had not been copyrighted till after they had been used in the way complained of. Frederick Samuel Price, a member of the Conference Executive of the Rechabites, said he went to see plaintiffs' manager, and asked prices for photographs for the souvenir. He said the understanding was that the photos were for the souvenir only, and no other book was at that time contemplated. In cross-examination he admitted that when he first saw plaintiffs' manager he had no authority, but before the completion of the agreement he was authorised to act.—Dr. Williams: Perhaps that is what is meant in your biography in the souvenir where it says you are "perhaps a wee bit too active?"—Yes.

Witness went on to say he did not give the order. John Joslin was called to prove distribution of the booklet in question. He said he did it at the direction of the secretary of his tent.—Dr. Williams: Who was that?—Witness: Mr. Price, the last witness. (Laughter.) The Judge: He engaged him to distribute things which he said he considered it very wrong to publish. Dr. Williams was opening the case for the defence when the judge interposed with the observation that it appeared to him Mr. Meager was complaining of an infringement of copyright not in existence at the time of the alleged infringement. Mr. Meager said 26 out of the 30 were taken previously, and the plaintiffs possessed the copyright, but it was necessary to have the copyright registered before the action could be brought. Dr. Williams read authorities in opposition to this contention, and then, at the suggestion of his Honour, called witnesses to speak as to the agreement with the plaintiffs. Messrs. R. Watkins, Tasker, and Stevens said they gave the order to plaintiffs, but denied there was any stipulation that the photos were only to be used in a particular publication. Eventually his Honour said that in view of the witnesses for the defence having declared that there was no restriction in the agreement, and Price having denied that he gave the order, judgment would be entered for the defendants with costs.

News and Notes.

We have received from Mr. Robert Banks, photographer, of 12, Market Street, Manchester, a copy of a recently published book of views of Manchester and the Ship Canal. The hundred photographs herein reproduced are full of interest to admirers of the great and progressive Lancashire city. Bound in leatherette, the book sells at 1s., and should be largely bought by Mancunians and others.

A complimentary dinner was given on Monday evening at the Café Royal to Major-General E. R. Festing, C.B., F.R.S., upon his retirement from the post of Director of the Science Division of the Victoria and Albert Museum. Among those present were Sir William Abney, F.R.S., Sir George Bartley, M.P., Sir Arthur Rücker, F.R.S., Sir Archibald Geikie, F.R.S., Major-General C. E. Webber, C.B., Mr. Thorpe, C.B., F.R.S., Professor Judd, C.B., F.R.S., Mr. Alan Cole, C.B., Sir Purdon Clarke, C.I.E., Mr. F. G. Ogilvie, Professor E. Lantéri, Mr. J. H. Teale, F.R.S., Professor Perry, F.R.S., Professor Farmer, F.R.S., Professor Tilden, F.R.S., Mr. J. C. G. Sykes, Captain Shaw, Professor Moira, and Mr. J. A. Grant.

The Prime Minister was the principal guest at a dinner party given at the House of Commons on Thursday last by Sir Benjamin Stone, M.P. Among the guests invited to meet Mr. Balfour were Sir Alfred Seale Haslam, M.P., Professor Dewar, F.R.S., Sir Archibald Geikie, F.R.S., his Highness the Aga Khan, Sir Robert Ball, F.R.S., Sir Edward Maunde Thompson, Sir John Batty Tuke, F.R.S., Dr. D. M'Kenzie, Mr. C. F. Hill, Mr. George Renwick, M.P., Professor Boyd-Dawkins, F.R.S., Mr. Henniker Heaton, M.P., Sir Norman Lockyer, Sir Robert Roper, M.P., Sir William Crookes, F.R.S., Sir John Evans, F.R.S., Sir Maxwell Lyte, Colonel Sadler, M.P., Mr. Dods Shaw, Sir Edwin Durning-Lawrence, M.P., and the Dean of Westminster. Sir Benjamin Stone exhibited to his guests a large collection of photographs taken by him in Algeria.

ARE we receiving less heat from the sun? Returns have lately been made to the Paris Academy of Sciences by M. Dufour and M. Ladislas Gorczynski which seem to show that such is the case. M. Dufour dates a marked diminution, beginning in December, 1902, and M. Gorczynski reports that it began at Warsaw in May of that year. Some observers are inclined to ascribe the decrease of solar radiation to the dust ejected from Mount Pelé, others to the increase of sun-spots. It is improbable that solar radiation varies sensibly from year to year; but the quantity of moisture in the air differs from day to day. 1879 was cold in England, not because solar radiation was less, but because the sky was nearly always cloudy. We observe solar heat and light at the bottom of an ocean of air, the changes in which must have far more to do with our records than alterations on the sun's surface, stupendous as these are. 1879 was a hot year in several countries, though a wet and cold one with us.

SIR NORMAN LOCKYER showed some interesting photographs and diagrams illustrating solar and meteorological changes, and a striking series of photographs to determine the relative temperature of the stars at the Royal Society's conversation last Friday. One photograph of especial interest illustrated the close connection between change of barometric pressure and rainfall, significant of the progress which is being made in this department. A very attractive exhibit under this head was that of Mr. J. Frankland Adams, consisting of transparencies and prints in illustration of a photographic atlas of the heavens, photographed at the Royal Observatory, Cape Town, 1903-4. The objects of Mr. Frankland Adams's expedition to the Cape were of great interest, including the elucidation of some problems of the Milky Way structure, especially as to possible extension beyond its limits generally accepted. Another was to secure records to allow counting stars and plotting areas of light for the Southern Milky Way, as has already been done for the Northern Milky Way. Mr. Frankland Adams proposes to publish a special photographic atlas for the use of investigators in this particular line, and it is to be hoped that the most useful enterprise will receive encouragement. The Royal Astronomical Society showed ten transparencies illustrative of sun-spot phenomena, from negatives taken with the Rumford Spectro-Heliograph of the Yerkes Observatory.

At a largely attended meeting of the South London Photographic Society on Monday, May 16, at Collyer Hall, High Street, Peckham, an interesting episode took place prior to a lecture by Mr. J. M. Sterry, hon. treasurer of the Royal Photographic Society, who explained his new process of controlling gradation in bromide prints and lantern slides. Mr. Sterry, before commencing his lecture, said it was a great pleasure to him to come down there that night, as he had lived twenty years on Peckham Rye, and he had not been there for twenty years, and he found the place very much altered since that time. He had been asked to perform what was to him a very pleasant thing to be able to do that evening, and that was on behalf of the Society to present a testimonial to their late president, Mr. Maurice Howell, who was one of the founders of the Society, and had been interested in it ever since in every way. If there had not been a Society when he lived at Peckham (for he was doing a little photographic work in 1860 and 1865 he gave it up then until 1888 he would have gladly joined it. He did not happen to know Mr. Howell, but he had great pleasure in asking him to accept the gifts in recognition of his services to the Society. Mr. Howell, amidst loud applause, was then presented with a very handsome silver cigarette case, bearing the following inscription: "Presented to Maurice Howell, Esquire, by members of the South London Photographic Society, as a small token of their esteem, May 16, 1904." He was also given a gold-mounted umbrella for Mrs. Howell.

EARLY MINIATURES.—At the Society of Arts last week an illustrated lecture on "Early Painting in Miniature" was given by Mr. R. I. Holmes, C.V.O., Windsor Librarian. Sir William Abney, F.R.S., presided, and there was a large attendance. The lecturer briefly characterised the chief miniature painters working in England from the time of Holbein to that of Cosway; but the chief feature of the evening was the remarkable series of lime-light illustrations, from "three-colour" photographs made from the original miniatures in the Royal Library, and enlarged to life-size. They were taken by the Sanger-Shepherd method, and though a few examples had failed and were not therefore shown by Mr. Holmes, the rest were little short of marvellous. Not only every line and shadow of the miniature has been caught and reproduced, but every tint and shade of colour so that the perfect miniatures came out perfect and those that were flawed or faded appeared as such. The famous "Mary Queen of Scots," by François Clouet; the full length "Sir Philip Sidney," by Isaac Oliver; the same painter's "thumb-nail" portrait of himself and the "Monmouth" and "Monk" of Samuel Cooper, the greatest of all miniaturists, were especially successful, and their appearance on the screen was warmly cheered. The triumph of the new process was demonstrated; henceforth it ought to be possible, by proceeding with care equal to that exercised by Mr. Holmes and the photographers, to make absolutely exact fac-similes, enlargements, or reductions of any painting, large or small. Incidentally, too, Mr. Holmes proved the truth of a saying of Horace Walpole, who wrote, "If glass could expand Cooper's miniatures to the size of Vandyke's, they would appear to have been painted to that proportion." Thrown in colour on the screen, they fairly rivalled Vandyke's pictures.

A gas balloon exploded on Thursday, May 12, in the Rue Edouard Robert, Paris, with the result that a number of people were seriously burnt and otherwise injured, whilst all the windows of houses in the locality were broken, and one house was set on fire. The event was an extraordinary one in many ways, says the Paris correspondent of the "Standard." During the morning, the Rev. Mr. n, the well-known photographic aeronaut, and a friend had made balloon ascent. As they were drifting over Paris, a sudden storm arose, and it seemed wise to make a hasty descent. Knowing the difficulties of a descent in the crowded streets, the aeronauts tried to rise in the air until they reached the more rural district of Vincennes; but, on reaching the lower regions, they were caught by a strong current which threatened to carry them back over the centre of the city. A rapid descent was consequently made, and the balloon, striking the housetops, landed in the Rue Edouard Robert, a narrow street on the eastern side of the city. Numbers of people rushed up to offer assistance, and to help the aeronauts. Unluckily a man was careless enough to go on smoking a cigar; and, the escaping gas coming into contact with it, a formidable explosion took place, the result of which was that the balloon, on at the same time catching fire. The shock of the explosion is described as terrible. Windows were blown to atoms, whilst people had crowded round the balloon were thrown violently to the ground. Only two persons are reported to be seriously injured, but sixteen others were more or less burnt or bruised. The explosion set fire to the first floor of 17, Rue Edouard Robert; but, help being at hand, the flames were quickly overcome. According to another account of the explosion, the balloon, in its descent, completely shattered the windows of the house, upon which one of the occupants succeeded in lighting a lamp, and it was this that set fire to the escaping gas. This, indeed, is the explanation given by the aeronauts; but other people who saw the accident state that the balloon caught fire beneath. Of the injured persons, eight have been detained at St. Antoine Hospital.

The World's Fair at St. Louis Great Britain makes a satisfactory contribution in regard to the leading scientific department—that of chemistry. The British Sub-Committee, which is composed of experts, states: "The recent achievements of Germany in the field of organic carbon chemistry, of which so brilliant an example is furnished in the great colour industry of that country, have perhaps, not generally, led to a widespread popular belief that, as regards chemical industry generally, Germany now occupies the predominant position. The general public, however, has scarcely been in a position to judge of the commercial importance of the chemistry and carbon products in relation to that of the industry as a whole, or to the extent of participation of other nations in those branches which lie outside the domain of organic chemistry. A study of this catalogue of British exhibits cannot fail to create astonishment at the wide-spread character of the exhibits, and when the value and output of various products are considered the reader can only arrive at the conclusion that synthetic organic chemistry constitutes but a small fraction of the whole. This being conceded, it becomes manifest that Great Britain still holds her own in the chemical industries of the world." The committee also furnish a list of British chemists and chemical processes discovered or worked out in Great and Greater Britain. Among the pioneers in chemical science are mentioned "Boyle, Cavendish, Dalton, Wollaston, Priestley, Davy, Faraday, Angus, Graham, Newlands, Percy, Abel, Muspratt, Frankland, Armstrong, Crookes, Dewar, Odling, O'Sullivan, Perkin, Ramsay, Roscoe, Thorne. Of these the last nine are happily still with us." Then, in the processes, they recite as British the Bessemer steel, the Deacon process, and Weldon's bleach processes, the preparation of coal-tar products, the Gilchrist-Thomas basic steel, the Solvay-Mond ammonia process, the Mond nickel and Mond power-gas, the McArthur-Forrest side gold extraction, the Messel-Squire sulphuric acid, and the Claus sulphur recovery processes. They append this moral: "We are to arrive at even an approximate estimate of the net financial results in terms of millions sterling that have accrued to the community from the work above referred to, it would constitute an impenetrable argument in favour of the encouragement by the nation of original research in chemistry, and of the education of students in the higher aspects of technology." To which may be added, as an official comment, that chemistry is the science which the British Government has neglected and taxed—in alcohol, for example—more than any other.

THE "B. J." JUBILEE. To the Editors.

Gentlemen,—I am looking forward with great pleasure to your jubilee number (doubtless it will have an enormous sale), as I am one of those old-time photographers who have read it pretty regularly for something like forty-five years. I have very much enjoyed what I may call the "looking-back" articles that have appeared lately. I often smile at the new inventions. Why, sir, the roller slide was invented by the man to whom I served my apprenticeship nearly fifty years ago, Mr. A. J. Melhuish. He brought it out for the wax paper process, but the wet collodion coming in soon after, it got thrown aside; although I recollect his taking a series of views of Oxford with it 20 x 18 at the time of the Russian War. Of course you don't want an old man like me to bother you, or I could tell of dry plates (Hill-Norriess's), a large number of which I used before I was twenty-one. I am now sixty-five. Then there are snapshot photos. They are only a development of Scaife's "pistolographs," of which I have some family portraits taken when I was sixteen or seventeen. Now you press a button, then you pulled a trigger like a pistol. I see there has been a talk of book illustration with stereoscopic views. Why, I printed, as a lad, hundreds for, I believe, your publishers in Henrietta Street. I recollect views at Tenerife by Piazzini Smith among others. It was a monthly the first number, having a folding stereoscope. Then, again, as to metal cameras, why, McLean, Melhuish, and Hayes established a factory for making them in Lisle Street, Leicester Square, over forty years ago; but I must stop or I shall tire you. I could write all night of leading men of those times—the Prince Consort, Glashier, etc., etc.—but have gone quite from my object in writing.—Yours truly,
J. P. S.

May 14, 1904.

To the Editors.

Gentlemen,—Fifty years ago, when the original of the BRITISH JOURNAL was founded, I was a toddling youngster of four, but I suppose I was born with an old head for young in life I got mixed up with journalism and science. I have a vivid recollection of the late Henry Greenwood and his peculiar characteristics and wonderful business acumen. Having had the advantage of the association with the late Samuel Highley (at one time on the Editorial staff of this journal) and getting a fair insight into optical matters while he was in business as an optician, I had opportunities of taking part in demonstrations and experiments that I should not have had with one whose sole object in business was money-making. This being so, and catching the fever of "ink-spilling," as it is inelegantly termed, I soon took to writing, for I gained confidence from the knowledge that great men with whom I had come in contact did not know some simple matters of a technical character.

The golden rule, as endorsed by our present genial Editor, in writing for the Press, and especially practical journals, is "to express yourself as if the reader was unacquainted with the subject and the tuition was for a novice." Those who are perfectly conversant with the subject need not read if their time is limited, but often the most experienced workers gain from the results of others. It is this principle of mutual help that has made the BRITISH JOURNAL OF PHOTOGRAPHY always a successful and popular journal. During a period of thirty years I have had the pleasure of writing occasionally, one might almost say consistently, to the Journal articles on Optics, Light, and Lantern matters, and for some years, on the introduction of the monthly supplement of the "Lantern Record," wrote regularly my "Lantern Mems," but business exigencies have prevented my writing much for publication for the past three years.

As, however, I have had the gratification of knowing as personal friends J. Traill Taylor, W. B. Bolton, and our present Editor, and writing for the Journal under each of their Editorship, I feel I must resume my pen and offer my congratulations to the proprietors, and

the reading photographic public on the completion of the fifty years of publication of the "B. J."

That it has served a useful part in the past goes without saying, and the magnificent progress can be noted in the size and style of the journal, and its paper and printing. When one thinks of the appearance and fall of many other journals devoted to photography and allied subjects, the cause for congratulation is intensified. The Almanac is a standing monument to the success of the "B. J.," and its remarkable advance in popularity and usefulness is exemplified by the gradual growth of the volumes that all good photographers regularly keep and add to their library. The row on my book-shelf is an object lesson to doubters, and an incentive to work and industry. I wish the BRITISH JOURNAL OF PHOTOGRAPHY continued success and a patriarchal life.—Yours truly,

G. R. BAKER.

6c, Sisters Avenue, Clapham Common, S.W.,
May 14, 1904.

SOME SPECTROSCOPIC EXPERIMENTS WITH TRI-COLOUR FILTERS.

To the Editors.

Gentlemen,—I notice that a few typographic errors occur in the above paper, printed last week, and should be glad if you would insert the following corrections:—

Page 391. The two sentences, starting on line 14 of the article, should read as follows:—"The yellow and blue-green regions will be narrow." "The colour filters and plates should be so adjusted to each other that the red negatives should record the red and yellow regions, the green negative should record the yellow, green, and blue-green, and the blue negative, the blue-green and blue-violet regions."

Then on page 393, first column, line 28:—"The region absorbed by the filter," should read, "The region absorbed by the dye."—Yours faithfully,

A. J. BULL.

London County Council School of
Photo-Engraving and Lithography,
6, Bolt Court, Fleet Street, E.C.
May 16, 1904.

MONOBROMO FLUORESCINE.

To the Editors.

Gentlemen,—With regard to the above-named dye, which was recommended by Dr. Eder as an excellent green sensitiser for collodion work, and which I stated could not be obtained commercially, Dr. Eder now states in the "Photographische Correspondenz," May, p. 216, that its manufacture has been undertaken by Meister Lucius and Brüning, of Höchst, a/M., and that they supply it in a pure state at 2 marks for 10 grammes.—Yours faithfully,

Foots Cray, May 14, 1904.

E. J. WALL.

PSYCHIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—As regards "Psychic Photographs" I would like an answer to what has always puzzled me. Who is the tailor that makes the shrouds or the dresses for them? I always thought that souls or spirits when leaving the body were dressed the same way as when born, and if I can admit that they leave the coffin (however they should leave the body before it is planted in some cemetery), how can they manage to leave the coffin all dressed as they appear on photographs? If souls can materialise to the extent of showing body, how about materialisation of cotton and wool, and maybe leather for the shoes? I want to believe, but I want a little explanation also. Who is the tailor and dressmaker for ladies departed?—Yours very truly,

A. LEVY.

Asnières (Seine), May 14, 1904.

MOTHERWELL EXHIBITION.

To the Editors.

Gentlemen,—I should be greatly obliged if you would kindly mention in the BRITISH JOURNAL OF PHOTOGRAPHY that the Motherwell Young Men's Institute Camera Club has decided to hold a third annual exhibition on November 3, 4, and 5, 1904, with five open classes and four members' classes. Silver and bronze plaques will be awarded. Messrs. William Crooke, Edinburgh, and William Goodwin, Glasgow, have consented to judge the exhibits.—Thanking you in anticipation, I am, yours faithfully,

JAMES DUNLOP, Hon. Secretary.

CHINESE PATENTS AND TRADEMARKS.

To the Editors.

Gentlemen,—In the Treaty which has just been ratified by the United States and China, there is the following clause through the most favoured nation clause of the Treaty of Tientsin is equally applicable to Great Britain, the words "Great Britain" being substituted for the United States in the clause.

The United States Government allows subjects of China to file their inventions in the United States and protects them in title and ownership of such patents. The Government of China agrees that it will establish a Patent Office. After this office has established and especial laws with regard to inventions have adopted it will thereupon, after payment of the prescribed issue certificates of protection, valid for a fixed term of years to citizens of the United States on all their patents issued by the United States in respect of articles the sale of which is lawful in China, which do not infringe on previous inventions of Chinese subjects in the same manner as patents are to be issued to subjects of China.

An inquiry has been made by His Majesty's Minister at Peking whether the Chinese Government have taken any steps to establish a Patent Office as provided in Article 10 of the American Treaty, the reply has not yet been obtained.

Hitherto China has been dead against patents of all kinds, and the history of China and Japan are remarkable instances of the absence of a patent law. In China and in Japan until a patent system was established, invention stopped at the point where it was no longer profitable to an individual to invent, as he could not keep his secret. In matters of manufacture, the Chinese and Japanese recipes for compositions had nearly reached perfection, but any invention which could not be worked without the public being able to make a copy, was not invented. Japan passed a very liberal patent law about twenty years ago, and its progress since then has been phenomenal; while China, equally civilised, has stagnated. The present Chinese Government, however, are now convinced that they must go in for modern improvements; hence this patent law.

In the British Treaty with China, signed at Shanghai, September 1902, is the following article in regard to trade-marks:—

"Inasmuch as the British Government afford protection to Chinese trade-marks against infringement, imitation, or colourable imitation by British subjects, the Chinese Government undertake to afford protection to British trade-marks against infringement, imitation, or colourable imitation by Chinese subjects."

"The Chinese Government further undertake that the Superintendent of Northern and of Southern trade shall establish within their respective jurisdictions under control of the Imperial Maritime Customs where foreign trade-marks may be registered, a system of payment of a reasonable fee."

Substantially this article has been reproduced in the United States Treaty. Through the kindness of the Marquess of Lansdowne we have received the following information: A working scheme for patent and trade-mark protection is now being evolved, and in the meantime a provisional registration office for trade-marks has been established at the Custom House at Shanghai, where we have a consular agent and the Chinese courts will presumably afford, as they have done in the past, substantial protection against counterfeit trade-marks on the part of Chinese subjects. The French, German, and English representatives have mutually arranged for the punishment in the Consular Courts of France, Germany, and England of subjects of these countries who infringe registered trade-marks, and in all probability the remaining Western nations will shortly do likewise.—Yours truly,

W. P. THOMPSON & Co.,
Chartered Patent Agents,
Liverpool and London.

British and Foreign Patent Office,
6, Lord Street, Liverpool,
May 16, 1904.

THE NORTHERN EXHIBITION.

To the Editors.

Gentlemen,—May I ask you to kindly afford me an opportunity of replying to Mr. Inston's communication, which appears in this week's issue of your journal, by trespassing further upon your valuable space? Mr. Inston has supplemented my letter with facts, facts, facts, and facts, and what bearing have Mr. Inston's facts upon the subject of my letter? Practically none; and the facts certainly not in line with any of the ordinary methods of business.

Mr. Inston's facts explain why I received no invitation to the opening ceremony, which, according to the Press, was such an enormous success? Or—may I ask?—were only a few selected for a special distinction, and, if so, why? The Royal extends its invitation, even though the whole of your work is rejected. Mr. Inston will excuse my saying it, but he has, in my opinion, entirely begged the question.

Mr. Inston's first "fact" relates to fees and catalogue. I maintain that every exhibitor was entitled to an acknowledgment for the amount of his remittance, whether that amount was two shillings or twenty. In my own case, I sent in a number of frames, and the amount of my fees was considerably more than the minimum, but have received no receipt. At Rotherham there are no hanging fees, but a catalogue is sent to each exhibitor.

With regard to the second fact, Mr. Inston says: "The charge for admission at the 'Northern' was 6d., and pass-out cheques were given." Is this a reason for not sending season tickets to exhibitors? What says your contemporary, the "Amateur Photographer"? May 6:—"A reasonable ground of complaint. The facility of a personal season ticket to every exhibitor is generally recognised as almost obligatory in the case of a well-managed exhibition."

Facts third and fourth. I am quite aware that the Walker Art Gallery and Cloak Rooms are the property of the Liverpool Corporation, and are managed under its direction; but does this condone the want of courtesy I experienced at the hands of its officials?

And now I come to Mr. Inston's last fact—No. 5. Excuse me, gentlemen, but really I must smile. He says: "No person outside the Liverpool Society spent a sovereign on the success of the Northern. . . . The gentleman who, not being a member of the Liverpool Society, paid the largest sum in entrance fees was not 'A Distressed Exhibitor.'" Is this, to quote Shakespeare, "the retort courteous or the quip modest"? Mr. Inston knows perfectly well that an exhibitor the mere hanging fees are a trifling detail compared with the preparation of special work, the cost of packing, the cost of transit to and from, and the general depreciation of one's frames. Should not these items be considered? They have to be paid. Is the hanging fees or the pictures that make an exhibition. If I were to total up my entire out-of-pocket expenses in connection with the Northern, including, of course, my visit to the exhibition, they could amount to probably double the sum named. But I have not complained of these matters at all; the whole tenor of my complaint on the beginning to the ending of the great "Northern" exhibition and which Mr. Inston has entirely ignored) is summed up in seven words, viz:—"the lack of a little common courtesy."

I beg in anticipation to thank you, and to state that I shall not trouble you further with correspondence on this subject, and I again have the honour to subscribe myself—Yours faithfully,
A DISTRESSED EXHIBITOR.

THE MONMOUTHSHIRE IRON AND STEEL TRADE.

To the Editors.

Gentlemen,—There is nothing in common with photography in the accompanying pamphlet, which, as you will see, refers principally to the "iron and steel trade." Still, you may perhaps find something interesting in the description given of the early methods of working and the changes and improvements which have from time to time taken place, and therefore in consideration of our old association of ideas in relation to photography, I have thought I would send you the pamphlet for perusal. The reproduction of the works is from a 10 x 8 negative taken by myself by the old wet collodion process about the year 1864, and the portrait is from a photo taken about the same time, but not by me. The work was taken with a 10 x 8 Ross triplet, and I think you will consider both photos fairly good.—Yours faithfully,
THOS. MITCHELL.

Flynnan, Harrow Road, Newport, Mon.

May, 1904.

[We have to thank our old correspondent, Colonel Mitchell, for the copy of his interesting brochure, which, besides giving the history of the great iron and steel works, contains some instructive reminiscences of labour and wages sixty years ago, the Chartist riots, etc. The frontispiece, a view of Abersychan Iron Works, is so good that it might have been taken yesterday with a highly corrected Anastigmat on a modern fine grain gelatine plate.—Eds. B.J.P.]

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

* * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

W. G. Honey 109, Patrick Street, Cork. Photograph of a Combination of Two Photographic Prints of Portrait of the King.

A. Holborn, 25, Stokes Croft, Bristol. Two Photographs of the Old Drawbridge, Bristol.

G. S. Bragge. "Sandercock" Midway, near Bardon-on-Trent. Photograph of Underground Workings in Granville Colliery, Saddlebrook.

J. S. Hazard, 27, Trafalgar Road, Greenwich. Photograph of Two Chimneys at Electric Generating Station, Greenwich.

W. H. Fischer, 19, Egerton Crescent, Withington, Manchester. Photograph of the Right Rev. Dr. Carswell.

G. A. Dean, 14, High Street, Rugby. Photograph of the Chemical School, Rugby School Grounds, Rugby.

"POISON."—Not necessary.

"A. L. C."—No doubt you may obtain it of Messrs. Mawson and Swan, Soho Square, London, W.

"T. P. C." (Tooting).—The prints you send are fair specimens of average studio work. You do not mention what your present salary is, but we should say that as a general operator your work would entitle you to about £2 to £2 10s. per week.

STUDIO QUERY.—CHANCELLOR AND SON say: "Can you oblige us with any information respecting high side-light studios? Is the system a success?" In reply: The system is certainly good, and many photographers follow it. Very many studios are in use lighted by this system. We do not reply to queries by post.

"A READER FOR 45 YEARS" (High Wycombe).—We should advise you to get your friend a pocket folding camera of the roll film type, which can be used for plates and flat cut films also. The latter will probably be found easier to manipulate, but for portability and convenience when travelling the daylight loading film spool has much to commend it.

COLORING PHOTOGRAPHS.—S. E. JONES says: "I have two photo colour sets (Judson's and Levetihan), and the book on same, 'Photo Miniatures.' The book is too advanced for me to do anything with it. Kindly name me a simple yet good book on same." In reply: We know of no simpler treatise than that you have. If you cannot understand that, we should advise you to get a few practical lessons from a good colourist.

VALUE OF LENS.—E. H. DEBENHAM asks: "Can you give me an idea of the value of a portrait lens about 5 in. to 6 in. focus, quick-acting covers, half-plate, bearing Stereoscopic Co.'s name?" In reply: We do not value second-hand apparatus. We may, however, tell you that it has but little market value. If it is of the focus you state, and a quick-acting one, we doubt very much if it will cover the half-plate size.

LENS QUERIES.—"PHOTO PHYSICS" asks: "(1) What will be the equivalent focus of the combinations when two lenses of principal foci 14 in. and 9 in. are combined together with a separation of 2.84 in. between the lenses? (2) What focus supplementary lens should be added to a 5 in. Anastigmat or Orthostigmat (any maker) to convert it into an 8 in. focus lens?" In reply: (1) Approximately 64 in. (2) A negative lens of approximately 13 in. focus.

ENAMELLING AND COLOURING.—"G. A." says: "(1) Kindly let me know, if possible, how to enamel with celluloid small photos such as are put into cheap miniatures? (2) Also best medium to use on glossy paper for use with water colours transparent?" In reply: (1) Soak the print in methylated spirit and then roll

with a hot roller, in contact with the celluloid. Suitable rollers are supplied by Fallowfield. (2) No medium is required if you use the coal-tar colours as supplied for the purpose by most of the larger dealers.

LENS QUERY.—E. A. BARTLETT says: "I have a R.R. Lens, $\frac{1}{4}$ -plate. No name on. Iris diaphragms. Will this be all right for portraits with a supplementary lens added? What is the effect of thus adding a supplementary lens? Also, what effect would two such supplementary lenses added have, and how should the two be fixed?" In reply: The lens as it is may, of course, be used for portraits. The object of supplementary lenses is either to increase or shorten the focus of the original. They may be had for either purpose. They are fixed in the front of the combination, and are mounted for that purpose.

AIR BUBBLES IN LENS.—"INQUIRER" writes: "I have just bought a Ross-Zeiss planar lens of fairly large size, and the glass has a number of bubbles in it. This, they tell me, is owing to the quality of the glass and does not affect it optically, or its commercial value. I would be much obliged if you will let me know if you consider that is the case, or whether the flaws in the glass would render it of less value if I wished to dispose of it?" In reply: In some of the new glasses used in modern lenses it is impossible to avoid air bubbles. They, however, in no way interfere with the working quality of the instrument, or its commercial value.

LENS QUERY.—"F. N." says: "(1) I have an offer of a Ross No. 3 portrait lens; it measures $4\frac{1}{2}$ in. across. Can you inform me if it is a suitable lens for taking groups of children? (2) Can you advise me what lens I should get for taking small heads for miniature? Some of these have to be very small, about the size of a shilling." In reply: (1) We think you are mistaken with regard to the size number of the lens. If it is $4\frac{1}{2}$ in. in diameter it is a No. 4. However, if it be either a No. 3 or a No. 4, it is a good lens for groups of children. But if the figures are posed in different planes the lens, like all others, will require stopping down in order to get them all in focus. (2) Any ordinary carte de visite lens will be suitable for the work.

RED TONES ON P.O.P.—"G. H. A." says: "Some time ago I saw in the BRITISH JOURNAL OF PHOTOGRAPHY a formula how to tone P.O.P. a scarlet colour. I should be glad if you would inform me in which number it can be found, or, if out of print, will you kindly repeat?" In reply: The information you require appeared in No. 2,145. Vol. 48, June 14, 1901. The formula was suggested by M. Helain, and is: Ammonium sulphocyanide, 5 grammes; potassium iodide, 1.50 grammes; water to 1,000 c.c., and add with constant stirring, dissolved in a little water chloride of gold, 0.25 gramme. This should be prepared as wanted. The prints should not be printed deeper than usual, and well washed prior to toning. When the desired tone has been attained, they should be again well washed, and fixed for at least fifteen minutes in a fifteen or twenty per cent. fresh solution of hypo. Toning takes about 35 to 40 minutes.

FAULTY LIGHTING.—"S. M." says: "I am an operator at a studio here; the lighting of same I cannot understand. There is top light and both side lights; the whole I can cover in with blue curtains. My trouble is this: However I arrange the blinds, I cannot avoid the light in the eyes of sitter. I enclose a print showing the large white spot which appears in all eyes, and which I cannot avoid. Of course this has to be spotted out on the print, but does not look well. Can you help me?" In reply: The specimen sent shows very faulty lighting generally. In a studio fitted with blinds such as you describe you should, if you understand your work, be able to get any kind of lighting on the sitter. In the example enclosed there is evidently too much direct front light. As you are an operator we should advise you to get your employer to instruct you in the lighting of the sitter.

STUDIO.—H. Tims writes: "Having noticed in the JOURNAL that you reply to photographers on matters photographic, I venture to ask your advice on the following matter:—I am building a studio on the H. P. Robinson plan (I enclose you a rough idea), but I was only intending to glaze the north side for a length of, say, 12 ft., beginning 3 ft. from back-yard end, at a height of 4 ft. 6 in. from floor, right

to ridge, which would leave 17 ft. blank wall. What I wish to know is, would the above amount of glass—12 ft. in length—be sufficient? I see H. P. Robinson advises the glazing of the whole of the U side, from end to end. The only advantage, so doing that I can see is that either end of the studio is thus available." In reply: Twelve feet of glass, as proposed, will be ample, if only one end of the studio be used. But by glazing the full length you have the opportunity of using either end, which is a very great convenience. In a studio of the dimensions shown in sketch plan, 4 ft., or 4 ft. 6 in., at either end may be opaque instead of three.

STUDIO QUERY.—S. W. VINES says: "I have a room 15 x 12 feet which has an east light. The source of light is two windows 6 ft. x $3\frac{1}{2}$ ft. Height from floor level to window-sill about 3 ft. I desire to use this room to take an occasional portrait. Can it be done satisfactorily as it stands by the judicious use of reflectors? If not, can you suggest any means of making it satisfactory? My work primarily is of a photo-mechanical character, the portraits being very occasional, so a studio is somewhat of a luxury. If you do not consider this thing possible, can you suggest any means of artificial lighting in conjunction with daylight or alone? I enclose a rough print of the class of portraiture which I practise and to which I have a leaning, and for the working of same do not think a 'studio' of the conventional type a sine qua non." In reply: There will be some difficulty in working the studio for full length portraits, like that you enclose, because it is so short. We should advise that, if you cannot increase its length, you work it diagonally. Place the sitter in one corner farthest from the light and the camera at the opposite one nearest the source of light. In future, write on one side of the paper only, if you please.

CARBON PRINTING.—"FAILURE" says: "I shall be very glad if you can give me a little information regarding the failures in the enclosed single transfer carbon prints. You will see the one on Whatman paper has small shiny specks in the dark shadows, and the one on canvas paper has the specks, and also in patches it is not in contact with the paper. Those patches come away in stripping the backing paper from the tissue in hot water. I may say that the ordinary single transfer prints are all right, of which I do a good many. It is only occasionally that I have these rough ones to do. I soak the rough paper in warm water about 70 or 80 degrees, for half an hour before mounting the exposed tissue, which I soak in water about 60 degrees, squeeze well, and place between blotting paper, with good pressure, for half an hour, and then start developing in water about 10 degrees or over. Do you think it makes any difference whether the rough paper is new or old? This I am using we have had in the house two or three years." In reply: There is always a little more difficulty in working with rough papers than smooth. Instead of soaking the transfer paper in water at so high temperature as 80 degrees we should advise you to soak for longer period in cooler water—say two or three hours at 65 degrees. Make the tissue softer before squeezing on transfer paper than is necessary with smooth paper, and allow longer time before developing. Do not be in a hurry to strip the tissue for the development. Transfer papers have a tendency to get harder by steeping. After two or three years it would be harder than when first issued by the makers.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

THE BRITISH JOURNAL OF PHOTOGRAPHY" JUBILEE NUMBER (1854-1904).

To celebrate the completion of the fiftieth year of the BRITISH JOURNAL OF PHOTOGRAPHY we shall issue on June 10 next a Special Jubilee Number of the publication, which is universally recognised as the oldest and most influential of its kind in the world.

The ordinary issue of the Journal of June 10 will be more than doubled in size in the text portion, and amongst other features will include, by way of supplement, an illustrated history of THE BRITISH JOURNAL OF PHOTOGRAPHY, with portraits and Biographies of the Eminent Men of Science, Journalists, and Photographers who have been identified with the conduct of the paper during the last fifty years.

As a souvenir of a unique celebration in photographic journalism the "B.J." Jubilee Number will undoubtedly be in enormous request, as it is not too much to say that the history of the paper during the half-century of its existence is most intimately bound up with the history of photography itself.

Of this Special Issue of THE BRITISH JOURNAL OF PHOTOGRAPHY many thousand extra copies will be printed, as the normal demand for the paper will be very largely augmented. Moreover, it is intended to give the Jubilee Number a specially organised world-wide distribution, so that the greatest possible publicity will be secured for the paper on the completion of its fiftieth year of existence,

EX CATHEDRA.

Radiation Notes.

While savants are deeply engaged in the endeavour to discover and explain the theory of the action of radium and cognate radiations, records of facts in connection with it continue to accumulate. A writer to the "English Mechanic" has sent copies of photographic negatives he has obtained through the agency of the thorium contained in the débris of incandescent mantles that had been in use for twelve months. A dry-plate was placed in the bottom of an "ordinary plate box," a piece of note-paper put over it, and on this were placed coins, pieces of metal, etc., covered with the crushed mantles. The whole was left undisturbed for eleven days. The result, which is reproduced by a process block in the pages of that journal for April 15, shows clearly the forms of the curious articles employed—coins, a key, a pen-nib, pieces of carbon, zinc, perforated zinc, copper, and tin-plate. In the issue for May 20 appears another illustration from the same contributor. It consists of silhouettes of various bodies produced by the thorium radiation acting through a sheet of aluminium 0.04in. thick. The writer, who signs himself "A. F. B.," states that he found no difference between the effects of light passing through green or red glows, thus showing the radiations to be of a different nature from that characterising the usual solar radiations.

* * *

Radium at Large.

We referred some little time ago to the disappointment of the inhabitants of Bath at the failure of their anticipations of a fortune to be realised by the extraction of radium from the famed waters of that city, which, though having been proved to exist, was shown not to be present in paying quantity. According to the "Peterborough Advertiser," the inhabitants of a certain portion of Huntingdonshire are likely to be in a similar state of pleasurable anticipation, radium having been discovered in the beds of Oxford clay, near Fletton, in that county. A long descriptive article, containing, however, no particulars, appears in that paper, but it is suggested that the discovery will make "brickfields better than goldmines." We would suggest to the writer the advisability of avoiding a repetition of the Bath fiasco, in counting chickens before they are hatched, and to take into consideration the facts marshalled in a paper by Professor J. J. Thomson, read before the Cambridge Philosophical Society, and, in brief, printed in these columns a little while ago. The paper described how radium had been found in a variety of places, but not in paying quantities—in the Cambridge gault, gravel from a pit, garden soil, sand from the seashore at Whitby, powdered glass, flour, precipitated silica. There is, of course, some sense for such roseate anticipations as those referred to, the price of radium being absolutely fabulous, and still

increasing, through the embargo laid upon the export from Austria of the substance it is extracted from—pitchblende. The requirements for therapeutical purposes has stimulated the demand which is almost daily increasing. Those who were fortunate enough to have made purchases when radium was first put upon the market are almost as lucky as the owners of shares once were in Devon Great Consols!

Radio-Active Bacteria.

The latest radiation curiosities were shown at the recent conversazione at the Royal Society. Photographs were produced from the radiations from masses of bacterial growth, which had been subjected to the action of radium emanations. These were placed between two sheets of non-radio-active glass placed in contact with a dry plate, and upon development in the ordinary way a dark area corresponding to the shape of the mass was shown. The bacterial radiation was sufficiently powerful to affect a plate through a double thickness of lead foil.

Atmospheric Transparency.

This subject, naturally possessing especial interest to photographers, seems to have attracted very general attention in 1902, and many observers in several parts of the world have recorded their observations upon it. There appears to be a general consensus of opinion that during the year 1902 there was a distinct, and even measurable, diminution in the transparency of the air to the sun's rays, and, further, that a return to what might be termed the normal took place some time in the succeeding year. The phenomenon was observed at Washington, and might, perhaps, have been the effect of some local cause, but for the fact that observers in other parts of the world had noted the same thing. It was shown that excess of moisture in the air could not have been the acting agent. The matter is considered so important, and, possibly, the basis of an explanation of other meteorological phenomena, that Professor Cleveland Abbe, United States Department of Agriculture (Weather Bureau), Washington, D.C., asks observers to send him any records that will assist in defining the dates of beginning and ending, and the extent of this change in transparency. Such records may consist of photometric or photographic observations of the brightness of stars, changes in the solar or stellar spectra, unusual prevalence of halos, large Bishop's rings or haze, observations of heat received from the sun as made with actinometers or pyrheliometers, observations of the polarisation of the blue sky light, and of the scintillations of the stars. It is proposed eventually to incorporate the results of these enquiries in a general article on the subject of atmospheric transparency. When it is remembered how strongly the whole surrounding atmosphere of the world was affected by the great Krakatau eruption, it appears to us highly probable that the effects we are referring to will prove to be traceable to the great volcanic catastrophe of Mont Pelée and the other West Indian irruptions. What gives the matter a particularly photographic interest is the fact that it was in what is usually looked upon as the photographic part of the spectrum—the violet and ultra-violet—that the effects were especially noticeable. It is unfortunate that at present we possess no absolute standard of actinism that the observations could be referred to, and if the discussion of the data received should lead to such standard being devised, a great gain to photographic technology would accrue.

London Landmarks.

"Going, Going, Gone," is the cry of many buildings in our Metropolis just now, for the Spirit of Destruction is abroad, and he does not stay his hand. It seems but the other day that the last

of London's galleried inns, "The Old Bell," in Holborn was demolished, and now its near neighbour, "The Black Bull," is in process of being pulled down. There was a little crowd on the opposite pavement on Wednesday week watching the operation of lowering the black bull which gave title to the place, from his proud perch on the second floor front, to the ground beneath. They were swathing the limbs of the black bull in canvas, and taking as much care of him as if he had been a human being. And we wondered if there was a camera bearer within the crowd who was able to take a photographic note of this interesting ceremony. If the shade of Charles Dickens still haunts the neighbourhood, which he knew so well, he would have been interested in the proceedings. For he lived in these old inns, and has drawn many a word-picture from them with more than photographic accuracy. And he generally made special mention of their signs—with his caustic remark about the celebrated "White Horse" which still stands in the High Street, at Ipswich. He would not say that this terrible animal "was supposed to have a distant resemblance to an insane cart horse"! He is not aware that he criticised the appearance of the Holborn "Black Bull," but he certainly alludes to the inn, as reference to "Martin Chuzzlewit" will show. We trust that the bull itself will not be destroyed, and care that was taken by the builders in wrapping it up previous to its descent to the ground warrants the belief that it is intended to be preserved. It is not only a memorial of our popular novelist, but it is a fair representative of those signs which used to distinguish all houses in business in the Metropolis, but are now found only on licensed premises and but seldom on those. It is curious within the bounds of possibility that the black bull has been purchased by some American admirer of Charles Dickens, for such things are prized on the other side of the Atlantic far more than they are here. The sign "The Wooden Midshipman," for example, would fetch a weight in gold any day from our American cousins. The proprietor in the Minorities care to part with it. Otherwise, the bull may find a resting place, together with other things of a like nature, in the Guildhall Museum. We never may be its ultimate fate, it, and relics like it, ought to be photographed, and the pictures should find a place in the national collection. Our streets may be too crowded with traffic to allow of such things as signs, and the London County Council set their face against anything of the kind, but there is every reason why memorials of the city, as it was known to our forefathers, should be carefully preserved, so that future generations may have tangible evidence of customs which are now dead and gone.

Trichromatic Lantern Slides.

When Sir William Abney is advertised to take the chair at a meeting or lecture, we may be quite sure that something of importance to photography is to be the subject of discussion. It was so at the Society of Arts the other night when Mr. Holmes, who, we understand, is the custodian of the various objects of art belonging to the Royal Collection at Windsor, lectured on "Early Painting in Miniature." The photographic interest was found in the beautiful manner in which the lecture was illustrated by trichromatic slides in colour, and those who practise that fascinating phase of photography would do well to ponder upon Sir William's words of warning concerning it, which persons of observation will admit were very much needed. He spoke very highly of the pictures shown, and gave a generous testimonial to the excellent work achieved by Mr. Sanger Shepherd, to whose process the slides were due. The lecturer had explained that in consequence of unforeseen difficulties attending the work, certain pictures

which did not quite satisfy him had been withheld. This brought words of commendation from the Chairman, who expressed the opinion that if only other people who produced three-colour work would be equally fastidious, and not allow such abominations to appear as were occasionally shown as the production of tri-chromatic photography, the process would not have acquired the bad name it has at the present time. No one who has followed the process of three-colour work will complain that this trenchant criticism is undeserved, and of course it applies more to attempts on paper than to lantern slides which show the process at its best, for the tones are not cut up into a network of dots, as they are bound to be when half-tone blocks are employed. There has been more than one attempt to start a journal with coloured illustrations printed by the three-colour method, but the work has been so poor that even a public which is by no means critical in the matter of art would not respond to the efforts made in their behalf by the too sanguine publishers. That the newspaper in colours will come in time we have no doubt, but it must be very much better than its predecessors if it comes to stay. Apart from this little incidental matter, the lecture was interesting to photographers because it opens up a variety of suggestions as to kindred subjects which can be effectively illustrated in a similar way. The lecturer prefaced his remarks by an apt quotation from Walpole's "Anecdotes of Painting," which was to the effect that if a glass could expand Cooper's pictures to the size of Vandyck's they would appear to have been painted to that proportion, so perfect were they in excellence of detail. The lecturer had longed to try the experiment, not only with Cooper's works but with similar paintings by other miniaturists, but that was impossible until the tri-chromatic method of producing lantern slides removed all difficulties. Mr. Holmes said nothing about the use of the opaque lantern by which small objects can be projected upon a screen, but no doubt he considered that expedient as being not worthy of mention by reason of the risk from heat to delicate painting, and the impossibility of removing objects from museums and private collections for exhibition in a lecture-room.

LOCAL TREATMENT IN CARBON PRINTING.

Many who are not really familiar with the carbon process do not seem to realise to the full the scope there is for modifying effects and introducing individuality in their pictures. Some appear to imagine that such effects are only to be obtained with gum-bichromate, or with platinum-type with glycerine developer applied locally. But the carbon process lends itself to local treatment as well as does either of those just mentioned. If this particular property of the carbon process were more fully realised by those who desire to show individuality in their pictures, they think that many, in practice, would prefer it to gum, mainly for the reason that the material may be purchased ready for use, and thus the worker would be saved the trouble of preparing his own pigmented paper, and often having to spend hours over the development of his pictures and sometimes having to resort to two or three pigmentings and printings in order to obtain sufficient depth in the shadows.

It is pointed out in all treatises on carbon printing the wide scope there is for correcting errors in the exposure in the development of the image. If over exposed it may be corrected by the employment of hotter water and allowing longer time for the development; conversely if the prints happen to be under-exposed the error can be corrected by using the water at a low temperature. Also

it is usually pointed out that in working, certain portions of the pictures can be brightened up by applying, locally, a stream of hotter water than that employed for the picture generally. All this is pretty well understood by the majority of carbon workers, but something more than that is desired by those who are desirous of introducing their individuality in their work, and it may be done in the way of "faking." We may, perhaps, be excused for using this term, but it has become a very generally accepted one when pictures have been "dodged" or the ordinary manipulations have been modified in their production. The term now has become pretty well understood, though it is somewhat uneuphonious, still its meaning is well understood in photography. Having said this much we shall now give a few practical hints as to the way of obtaining the same advantages with carbon, as regards control in local treatment, as with gum or platinum-type.

In the first place, it may be well to make a silver print from the negative, and determine from that what is desired in the finished picture. The carbon tissue employed should be in a fairly soluble condition and not at all stale. If it be decided from the silver print that much local treatment has to be done, the tissue should be but very lightly printed, so lightly, indeed, that it would, under the ordinary conditions of working, be considered much under-exposed. If the print is at all over-exposed it is fatal to any great extent of local treatment. The beginner will do well to employ, at first, the single transfer method, as with that any grade, or tint, of paper may be employed. Furthermore, the image on the single transfer paper will permit of much rougher treatment than when it is on a temporary support, whatever that may be. After a little experience has been gained in extreme faking, the double transfer method may be used without any great difficulty.

We shall not here go into the working details of the carbon process, but at once assume that they are already well understood; therefore, we shall proceed with the manipulatory part of the work which, by the way, should be commenced soon after the tissue has been exposed, so that no "continuing action" takes place. The tissue, which has received but the minimum of exposure, is mounted on the transfer paper—rough or smooth—in the ordinary way, and after resting the usual time the print is put into water at a temperature of 95° or 100° F., and the backing paper stripped off as usual. Then the print is at once transferred to cooler water—say, 80° F. This will almost arrest development. Now, having decided, from the silver print, the effect desired, we, with a camel's hair brush dipped in warmer water, proceed to clear away the unaltered pigmented gelatine from the lights it is intended to emphasise, leaving the other portions to take care of themselves for the time being. After resting a little, while the picture is very slowly developing, the effect obtained will be seen, and other portions can then be locally dealt with. At this stage the picture will be very much under-developed.

When it is judged that the effect desired is approximately obtained, the picture should be put into warmer water—say, 90°—and allowed to develop by itself for a time. Then the general effect will the better be judged of. If further treatment is desirable the picture should be replaced in the cooler water and the brush treatment with hotter water repeated. Should the shadows seem to be getting lighter than is desirable, the development of them may be checked by the application of quite cold water applied either from a jug or a brush. At this stage the picture should still be considerably darker than it is to be when finished. When all the effects that are desired at this dark stage are satisfactory the print is once more transferred to water at the temperature of—say, 100° to

105° F., and the development completed in the usual way. The great thing in local treatment, when much has to be done in carbon printing, is to commence the principal part of the work at a very early stage, and complete it before the print has become fully developed. When this is done the finished result, if the work is carefully done, will bear no evidence of having received any local treatment at all.

Supposing when the picture is fully developed it seems capable of further improvement—say, by way of example, by having some heavy shadows made lighter—it may be done in the following way: Let the print be closely drained. Then a camel's hair brush dipped in diluted ammonia—say, 1-10—may be applied to the portions desired to be lightened, this treatment renders the gelatine where it is applied very soluble even in tolerably cool water. If, then, the print be put into water about 85° to 90° F. the pigment gelatine will be dissolved away leaving the other parts quite unaffected.

In this article we have not attempted to deal with all the "faking" that may be accomplished in the carbon process, but we have said sufficient to indicate to those who are not aware of the fact that as much, or more, in that direction may be done as with any other process, and perhaps with less trouble to the worker.

ON THINGS IN GENERAL.

A LAW case of fresh interest to photographers was tried the other day, and, strange to say, has met with very little comment among those so much interested as the professional portraitist.

Briefly, the suit, which was tried in the final Court of Appeal in this country, of course, will now stand as an important precedent, was over the infringement of rights of light. Hitherto, a man whose lights had been diminished by the erection of a building or other obstacle has been considered to have a perfect case for obtaining legal redress. This appeal, now over, has settled that, though an occupier's access of light may be reduced, he has no remedy if it can be proved that the residual light is sufficient for the purposes of his business. It seems hard from one aspect, common sense from another. It, however, ignores the fact that the amount of illumination which would suffice for one kind of business might not be enough for another, and so the premises whose light was interfered with would be reduced in order inasmuch as their lettable possibilities would be circumscribed. Possibly it will be held that photographers are not interested, as the slightest infringement of their lights would militate against the conduct of their profession at all times in all kinds of light. Unfortunately, let that be granted, there would still remain the fact that another was added to the list of the law's uncertainties, and the doubt as to how a jury would treat the matter would cause many to pause who, before this decision, would have felt they had a "good case." A case in point may be quoted.

Not very long ago a portrait photographer in the provinces had his studio lights interfered with by the erection of a large building overlooking his premises, the building being persisted in in spite of protests. Eventually, on the eve of a trial at assize, a compromise involving the receipt as solatium of about a thousand pounds was arrived at. It is evident that if this recent appeal case had then existed as a precedent the infringers would have been so armed as to permit them to take a stiffer attitude in the negotiations, if, indeed, it did not induce them to stand the risk of a trial. There is one point about rights of light not generally understood that may be here attended to. It requires that twenty years of uninterrupted enjoyment of

a light before a legal right to possess it accrues; but the failure to make any use of such light, or the permitting its obstruction, for a couple of years, extinguishes the right altogether. Another point useful in practice may be referred to. A tenant or owner puts a window in a hitherto blank wall, separated or not by a passage from a neighbouring tenement; it is commonly thought that the neighbour thus newly overlooked can compel the window to be removed as "he has no right to it." But this is all wrong. His only remedy is to put up an obstacle to prevent light arriving at the new window, and such obstacle must not, in any part, obstruct the light that arrives at any other window beyond the offending one. When a passage intervenes this obstruction-building may be both difficult and costly. And even when no passage intervenes and the properties adjoin one another, the obstruction to be erected must not be attached by nails, etc., to the offender's wall. So that if it be elected to board up the window the boards must have their support from outside sources.

In the May 13 number of this journal is a letter from "A Provincial Photographer," which is so very one-sided that it needs a corrective. The burden of the writer is that among the hosts of applicants for the post of operator there are so few competent men, and that the cause of this is the taking of artied pupils with premiums by firms of wide repute and the turning out of assistants not knowing their business. Now, as a matter of fact, it would be interesting to know how many of these incompetents have been premiumed pupils. I am sure the proportion would be found to be infinitesimal. Even if this were not so does anyone imagine for one moment that the taking of a fee includes a guarantee of efficiency at the end of the term? The thing is absurd on the face of it. Does the articling a solicitor's pupil or the paying of a medical student's fees guarantee a successful début to the pupil at the end of the period? Of course not. How many wasted lives could trace their downfall to a misspent attempt at a professional career. It is the man and not the means that tells, and fortunate it is that should be the case in all professions, as, otherwise, all would be crowded to death through the absence of misfits, and it would add still more to the professional portraitist's troubles if ready-made operators could be produced thus abundantly. As to the other side of the question whether there is any use at all in spending money in having a youth taught business like photography which is so easily picked up I can only quote the opinion of an old professional who said he had a son well up in his work, yet he would gladly give a hundred or two pounds for him to have an opportunity of picking up what he could at a first-class studio for a year or two! When a man has learnt how to make a good negative he is only just beginning to learn professional photography. The country teems with failures of good men, possessed of capital too, to make a business through want of familiarity with the everyday work of a studio. It must ever be borne in mind that by going to an established studio to learn a business the learner has all the advantage of the experience of those who have succeeded when others have gone to the wall, who have learnt by losses and failures, and have arrived at success by the elimination of similar sources of loss, and at ability by years of practice. I should like to think that we have heard the last of the turpitude of premium-taking photographers; but I fear we have not.

The recrudescence of interest in spook photography is not, on this occasion, the concomitant of the big gooseberry season, though it will by many be allied to it. For one thing, it is a little early. Yet, after all, we do not know that big gooseberries have been produced, and photo-

graphs with representations of a spook or its substitute have been seen. The marvel is so great that no one (or hardly ever) one will believe in the genuineness of any such representation in the production of which he has not had a hand as watcher or otherwise. For example, I have handled a photograph of a house, in front of which and unmistakably three full-length standing figures; yet I am sacredly assured that only two figures were present in the body when the view was taken, though the original of one of the two figures had recently lost a relative to whom this third figure bore a striking resemblance. Yet I am not convinced. Though neither negative nor print has been faked, I am certain that the presence of a spook is not the only explanation of there being a third figure present!

A copyright action that failed the other day is, nevertheless, of interest on special grounds. It is usually thought that to obtain an injunction against infringement of even damages resort must be had to a High Court with its costly fees. But at Swansea, a week or two ago, an action was brought in the County Court against trustees of the Independent Order of Rechabites for infringing the copyright of photographs of the district by a local photographer. The action failed, not because the Court was not entitled to adjudicate on such actions, but simply on that might be termed a technical point—the plaintiff failed to prove the special arrangement under which he admitted the photographs had been taken entitling him to the copyright.

The recent discussion on photographers' prices at the P.A. was well-timed. A general agreement on principles would be very advantageous, especially if it tended to the fixing of a price for a simple picture only. The general public have been so spoiled by "spec" pictures that it so often happens that they feel indignant when asked to pay for a photograph they "do not like," though they admit the picture is excellently taken, and the failure to lease is owing to no fault of the photographer. Yet, lamentable as it may sound, it is nevertheless true that they will not hesitate to take such rejected picture and have it copied—possibly by a man in a garret with a capital, all told, of a few sovereigns!

FREE LANCE.

LADY CONAN DOYLE and Mrs. Thomas Hardy have consented to adjudicate on the new "Tatler" prize competition for photographs of the three most beautiful children in the British Isles.

"PHOTOGRAPHY is a strange profession," muses the young man. "Because it develops negatives?" asks the young woman, with a knowing look. "Not that, exactly. But, as an example, the other day I had my picture taken in my riding togs—not on a horse, you know, but just standing in my riding outfit, with my crop held in my hand. And to-day the photographer writes me: that the pictures are ready for me, and that they are all mounted."—"Judge."

It seems, according to the "Bulletin de la Société Astronomique de France," that M. Lucien Rudaux, of Donville, in the Department of Manche, narrowly missed being the first discoverer of comet α , 1904. Having taken a photograph of part of the constellation Hercules on the evening of the 16th ult., he noticed, on developing the plate, a slight nebulosity between the star 52 Herculis and the cluster M 92. Before he could compare its place with the stars again the sky had become cloudy, and was so again on the following evenings. If we allow for the difference of longitude, the time of the photograph (about 10h. 30m., Paris time) was about four hours before that of the actual discovery by Mr. Brooks at Geneva, N.Y. The "Astronomer-Royal" communicates to the "Astronomische Nachrichten" three accurate places of the comet obtained from photographs taken with the astrographic equatorial and the 50 in. reflector of the Thompson equatorial at the Royal Observatory, Greenwich, on the nights of the 17th, 18th, and 19th ult. The comet is now only about half as bright as it was when discovered.

PHOTOGRAPHY AS A PROFESSION AND AS A RECREATION.

[The "Blanc" Prize Essay: A paper read before the Edinburgh Photographic Society.]

THE labours and recreations of men form an ever-interesting study. Looking out upon the world we see a vast army of workers, engaged in many different forms of employment, yet all having their place in the great economy of labour. In accordance with the law of supply and demand, the varied and numerous wants of men have created many fields of labour which are open to the aspiring worker. Different minds and tastes select different forms of activity, and thus we find that labour, which is, practically speaking, common to all men, takes forms innumerable. Then, if we look at the recreations of men, we see that these, too, are many and varied. Some demand physical energy and endurance in no small degree, while in others the intellectual or imaginative faculties are alone brought into play. The place which photography occupies among the professions and recreations of men, and the attractions which it offers in both connections, must be of interest to us, as members of a Photographic Society which exists for the promotion and culture of art. It is hardly necessary, I think, in this the twentieth century, to claim that photography, whether we take it as a profession or as a hobby, has a real and indispensable place. It cannot be denied that photography has become a necessity of modern life.

AS A PROFESSION.

Let us look for a little at photography as a profession, and at the inducements which it offers to those who enter it. As a general rule, the considerations which influence one about to enter any business or profession are twofold. Firstly, is the work likely to be congenial, and to employ and develop any special talent which he may have? And, secondly, would it pay? In considering these two questions in relation to photography, it would be well first to notice the general nature of modern professional work, and some of the qualifications which are necessary to success in it. During the last twenty or thirty years a great change has taken place in the work of professional photographers. Up till that time the development of photography had almost entirely taken place on its technical and scientific side. The names of Niépce, Daguerre, Fox Talbot, and others are associated with discoveries which have given them high places of honour as contributors to the development of an important branch of human knowledge. But for many years after these had finished their labours, the artistic possibilities of photography were still undreamt of; and we see, from the examples which are still preserved to us of the work of the earlier professional photographers, that technical excellence alone was their highest aim. And it must be admitted that in many cases their work, as regards technique, reached a high standard, and for enduring quality compares well with much of the work produced to-day. From an artistic point of view, however, the results, especially in portraiture, were generally very crude. The portraits were almost all full-length ones, and the position, background, accessories, and style of lighting were the same for all classes of subjects. All that was expected and desired was a purely mechanical reproduction of face and figure. As has been said, within the last twenty or thirty years this conception of photographic portraiture has been entirely changed. This change is due to several causes. Undoubtedly the spread of education and culture has had a considerable effect in diffusing a knowledge and love of the beautiful and artistic among the great masses of the people, and has led them to demand a higher standard of excellence in photographic portraiture, as in other things. One of the most important causes, however, has been the introduction of the dry plate and the perfection to which it has attained. Owing to the greatly increased convenience in working, this resulted in photography being used by many who did not adopt it as

a profession, but who employed it solely as a means of artistic expression. While the efforts of such workers have been mainly confined to landscape and seascape photography, they have undoubtedly helped to quicken the development of professional and studio work. Again, the introduction of the platinotype, and the greater use of the carbon process, gave to the photographer more suitable mediums for the expression of his artistic conceptions.

THE ARTISTIC INSTINCT.

But perhaps the most important cause has been the entrance into the ranks of professional workers of men of artistic instinct and high technical ability; men who had more than a commercial interest in their business, and who have worked hard and conscientiously to raise the photographic art to the high place to which it has attained to-day. It is flattering to our national pride to know that Scottish workers have been in the van of this progressive movement, and that the reputations of many who are still with us are amongst the highest in the photographic world. To ensure success, then, in professional photography to-day, a man must possess the artistic instinct. It is not a case of placing the sitter in front of the camera, turning a handle or working a screw, putting in a plate, and leaving the rest to Providence. Position, background, and style of lighting must all be carefully considered, so that full justice may be done to the subject. More than a mere mechanical likeness should be aimed at. There should be an endeavour to convey, in the photograph, some idea of the personality of the subject, to show something of the character and temperament; and the nearer the photographer comes to achieving this, the closer he comes to the ideal. Here the art of portraiture finds its highest development, and, while it takes years of study and experience to attain proficiency in this direction, the young worker, by ever keeping these ideals before him, will make steady progress towards it. Then, to secure any but temporary success, the photographer, whether professional or amateur, must be a careful and patient worker. There are few businesses or professions where more constant care is required. The good work done in one department may be entirely destroyed by a little carelessness in another. The necessary carefulness, however, is generally taught by sad experience—the most efficient of all teachers. Although there are many good professional photographers who are by no means so patient as they might be, still the possession of this quality is very helpful, especially in the photographing of children. The angelic-like qualities so universally attributed to children are sometimes most conspicuous by their absence in the studio, and only by tact and patience can a good result then be obtained. Infants who can only blink and scream are brought to be photographed, on whom waving and flapping and the most seductive noises which horns and rattles can produce have absolutely no effect. These and many other things try the patience and skill of the professional photographer. And yet, with all its worries (and no business or profession is without these), the work is of a most interesting kind. While I have mainly referred to studio work, which perhaps would possess the greatest attraction for the student of human nature, every branch of photography has its own peculiar interest. Photography in recent years has taken a much higher place as a profession than it had previously done. Photography has been recognised as a distinct and important branch of art, and the exhibitions of the work of our leading professionals have been favourably commented on by the Press and the public. Professional photographers, too, have recognised the necessity of union and combined action. The Professional Photographers' Association and the Copyright Union have already done excellent work, and only need to be well supported to have a powerful influence.

THE COMMERCIAL SIDE.

On its commercial side, photography cannot be said to have made the same progress as it has on the artistic and technical

side. One reason for this is that men who are admitted to the artistic side of the profession are often possessed of little or no business ability, and so they suffer in competition of modern life. Like most other businesses, it has suffered in the general demand for cheapness. It also suffered from the want of combined action among photographers in regard to such matters as the training of apprentices, the regulation of prices for published photographs, also in other ways. As has been said, however, the societies mentioned are tackling some of these questions, doubtless some improvement will result. As to the remuneration which a man may expect under an employer, it is difficult to state any standard or fixed sum. With the absence of union, a man has been able to command as much as he worth. If a man has ability and some artistic feeling, there should be no difficulty in his getting a post where the remuneration would compare very favourably with that of most businesses or professions. Although, as has been said, professional photography has suffered somewhat on its commercial side, its position as a remunerative business is still fairly satisfactory. New fields of action are constantly being opened and the enterprising professional need not confine his energies to studio and portrait work. A recent example of this has been the extraordinary development of picture postcard work, which would have been more taken advantage of by professional photographers than it has been. There is no doubt that a firm turn out first-class work, whether in studio portraiture or in any other department, that work will be their advertisement, and they will be certain to receive a satisfactory share of public patronage.

AS A RECREATION.

While the number who to-day practise photography as a work and profession is by no means inconsiderable, it is nothing compared with the number who practise it as a hobby or recreation. In the days of wet-plates, as can be well understood, the number of amateur photographers was very limited, though some enthusiastic spirits braved the discomforts and difficulties which then attended the practice of photography in order to pursue their favourite hobby. But, with the advent of the dry-plate and the improvements which have taken place in apparatus, the number of the unpaid devotees of the hobby has greatly increased. The introduction and great development of the hand camera, too, brought another, and perhaps rather different, class into the ranks of amateur photographers. There are, generally speaking, two classes of amateur workers. One class, among whom are numbered the more serious workers, have a direct interest in the technical or scientific side of photography, or use photography as a means of expressing their more or less defined artistic feeling. The other class have little or no interest in, or knowledge of, photography, but use the camera as a means of obtaining permanent impressions of the places which they visit or of the people whom they wish to remember. The great majority of the latter class use the hand camera for its greater convenience and portability, many of them may be seen at any popular watering-place or holiday resort during the season. Very often their photographic operations are confined to pressing the button or squeezing the ball, the city photographer or photographic dealer relieving them of the rest of the work. They are, however, by no means to be despised because of that. Many people have no natural liking for photography, while some have not the leisure to gain a fair knowledge of its technique; and yet they may find pleasure in obtaining photographs of scenes which they visit, or of friends whom they may meet, and if they care to obtain them in the easiest way possible, no one has any right to condemn them. But while that is so, it must be said that the rest of such work contain a large percentage of failures. The dealer or professional photographer who may get the plates and films to develop finds, as a rule, that many of them are use-

om fog, double-exposure, movement, or errors in exposure. Successful hand-camera work cannot be done without at least fair knowledge of the technique, as well as of the limitations and possibilities of photography. But by far the larger class of amateur workers proceed on lines very different from those above indicated. They enter upon the pursuit of the photographic art because of the attractions which it offers in itself, and it cannot be denied, as has been already suggested, that the artistic development of photography has been due, in great measure, to the efforts of amateur workers. This is especially true of landscape and seascape work, which, naturally perhaps, have never received the same attention from professional photographers.

PORTRAITURE BY AMATEURS.

Portraiture, however, has seldom been successfully attempted by the ordinary amateur worker. The lenses with which he is usually supplied are unsuitable for artistic portraiture, and the difficulty of controlling the lighting to suit the subject either in a room or outdoors is very great. Certainly many amateur workers have produced fine portrait studies, but, generally speaking, the energies of the amateur photographer are more successfully directed towards landscape and seascape work; and surely in these there is ample scope for his energies and for the development of his artistic instinct. The beauties of hill and valley, the winding rivers and the branching trees, the stretches of moorland, or the picturesque cottage, and the ever-changing panorama of sea and sky are worthy subjects for his camera, and provide him with abundant opportunity for showing whether or not he possesses any powers of artistic expression. When the amateur photographer has got over the preliminary difficulties of technique, in most cases he or she finds a great pleasure in the pursuit of the hobby. Many are discouraged by the non-success at first, and give up the attempt altogether. It certainly has a depressing effect on one, when, after spending a warm summer day in carrying a half-plate outfit over many a weary mile, and exposing plates on scenes which look beautiful and charming, to find, after coming home, and after having with much painful preparation and effort succeeded in developing them, that they are all spoiled, either because of technical faults or because the scene which looked so beautiful to the eye photographs poorly and disappointingly. These are trials which every photographer experiences at first, and which patience and perseverance overcome in time. And once a good working knowledge of the camera is acquired, more pleasure can be taken in its use as an artistic medium. If a man has had no definite art training, his first artistic efforts in photography will be pretty much groping in the dark. If he seeks inspiration and help by studying the walls of our photographic exhibitions, and the pictures which have been singled out by the judges, he may be still further confused. The fact that Art cannot be contained in any creed or set forth in any code of rules, and while a knowledge of the general laws of pictorial composition will be helpful, they need not be slavishly adhered to. The beginner is better not to follow the example of any extreme school until he is sure of his own conception of Art.

LANDSCAPE PHOTOGRAPHY.

Early landscape photography was faulty because it showed unwelcome details as prominently as the principal objects in the picture. "Sharpness all over" was then the motto. This has been changed, but like most reforms in their first sweep, the change has gone too far in the other direction. Even now there is a reaction against the extreme lengths to which the "fussy type" school has gone. A blurred mass which might be anything is not necessarily artistic. As has been said, the beginner should feel his way first, and then should seek to put as much individuality into his work as possible. Do not let him copy the style of any one else, however good it may be, but let him strike out a new line for himself. If he is a

lover of Nature in all her moods, he will see beauties in her which possibly have not been observed by other men. Let him try in his pictures to express the feelings which Nature inspires in him, and the better he does this the truer the artist he will be. The poetic descriptions of the external beauties of Nature which thrill us and which are assured of immortality are not those which merely describe her charms. It is those which go deeper, and which tell us of the feelings and emotions which these beauties have inspired in the poet's heart. So it has been, too, with the men whose names have adorned the world of Art in all ages. Their work has been so characteristic and full of individual feeling as to be easily distinguished from all others. While perhaps not to such an extent as the poet or the painter, the photographer has nevertheless in his camera an excellent medium for the artistic expression of imaginative thought. He, too, as well as the poet or the painter, may show that—

"There is a pleasure in the pathless woods,
There is a rapture on the lonely shore,
There is a society where none intrudes,
By the deep sea, and the music in its roar."

It is in the use of the camera towards this end that the serious amateur worker will find the greatest pleasure in his hobby; and it is gratifying to know that there are many who have done and who are still doing work which is not only creditable to themselves and a pleasure to others, but which is also an honour to the art which they practise. Photography will perhaps never become a popular hobby, in the ordinary sense of the word. One drawback to its general use is the expense. Materials and apparatus have in recent years, however, become much cheaper, and doubtless in time the practice of the photographic art will be within the reach of all. That the amateur will greatly encroach upon the field of the professional worker is hardly to be feared. Many good amateur photographers are among the best patrons professionals have. In many ways a knowledge of photography enables a man to appreciate better a good example of professional work when he sees it. Here, as in everything else, of course a little knowledge is a dangerous thing, and it is generally the man who knows little about photography who troubles the professional photographer with gratuitous criticism of his work. There is ample room for both classes of workers, and one of the best features of such societies as "The Edinburgh Photographic Society" is the intercourse which takes place between professional and amateur members. It is well for every worker, however humble be his achievements, to realise that he may do something to enrich men's knowledge of the beautiful and artistic through the medium of photography, whether it be to him a life-work or only the occupation of his leisure hours.

J. DRUMMOND SHIELDS.

THE engagement is announced of Mr. Reginald K. Morcom, eldest son of Mr. Alfred Morcom, of Birmingham, and Miss Isobel Swan, third daughter of Dr. J. Wilson Swan, F.R.S.

THE Royal Photographic Society of Great Britain, 66, Russell Square, W.C. Technical meeting, Tuesday, May 31, 1904, at 8 p.m. "The Practical Performance of Tricolour Filters: Being some Experiments to Determine the Best Form of Spectrum Record for Three-Colour Filters," by A. J. Newton and A. J. Bull. "Photography in Relief," by Carlo Baese.

M. CHEVALIER, the eminent French explorer, has recently returned from prolonged travel in Central Africa. He has secured a valuable collection of interesting documents and photographs of the country and its people. Furthermore, he carried on his travels a phonograph, upon which he has secured records of the languages of the various natives in the region which he explored, made by the natives themselves. These records will be reproduced by M. Chevalier in the course of his lectures describing his travels, experiences, and discoveries.

THE COMPOSITION OF COLOUR-FILTERS FOR THE PRODUCTION OF PORTRAITS IN NATURAL COLOURS.

[Translated by Harry Dietrich, and reprinted from the "Photo-Times Bulletin."]

So many formulas for making dry and liquid filters for the three-colour process have already been given that a further publication in this direction seems to be almost useless. If, nevertheless, I make known my experiences in this direction, it is done with consideration of the fact that good work of this kind is pretty scarce yet, and that the selection of the filters has not met with the proper estimation. It is pretty difficult to produce correct filters for the three-colour print, but considerably greater is the difficulty to reduce the time of exposure to a minimum.

The opinion has been general among photographers that hand-retouching of the negatives is unavoidable in the three-colour printing process, and that this hand-retouching constitutes an essential part of the work. This erroneous opinion has its origin in the reproduction establishments which produce autotypic three-colour clichés; but Vogel has already shown that with a clever selection of the filters a good and complete reproduction of the colours of the original can be obtained by lichtdruck without any retouching, and the latest works produced by Fritsch, after my process by lichtdruck, prove that the absolutely natural, correct reproduction of the original, to the smallest detail of colour by way of the subtractive colour synthesis, is not only possible in lichtdruck but can be obtained even lastingly and with fullest safety. The ruling points in the production of colour filters for portraiture have their source essentially in the desire to reduce the time of exposure as much as possible. This, above all, can be obtained with the red filter, but only with certain means, whose careful selection essentially determines the time of exposure. I may be permitted here to call attention to some points which determine the selected filter colour media and their composition. The theory of the subtractive colour synthesis, as is known, how managed by the gum print, the three-colour pigment process, the lichtdruck, etc., requires such a gradation of the filters that at each single exposure of those colours of the spectrum are excluded which are reflected by the print-colour. Therefore, the filter for the blue print is essentially red, for the red print essentially green, and for the yellow print essentially blue transparent. If an ideal dry plate of panchromatic action would be at our disposal this would determine everything necessary. Nothing else would be required but to graduate the absorption spectrum of the filter in such a way that it would complete with the absorption spectrum of the print colour at striking light to a full spectrum with correct distribution of brightness in all its details. Hereby the subtractive filters, if used for every printing process, place themselves in direct opposition to the so-called additive filters, which are not applicable for printing processes, or at least very limited, and must be in such a state that their mutual absorption spectrum, joined together, results again in a normal spectrum with correct distribution of brightness. If the nature of the filters with print and with the additive synthesis prescribed by theory is determined the matter is essentially different at the execution of the process with consideration of the applied plate, and from this the numerous mistakes are explained, which prevail upon this field, and have even been published lately to a considerable extent. If we take up the nature of the three-colour print in the form as given by its inventor, we can pronounce it only as that printing method for the reproduction of colours by which exposure filter and print colour possess supplementary colours, whereby we will understand by supplementary colours such colour aggregates, which complete themselves to a completely continuous spectrum of normal distribution of brightness. This correct definition of the three-colour spirit is, therefore, not to be changed with the perception of possibility to produce all complementary colours

with the aid of the three-colour, an idea which was represented already by Newton and executed by his contemporaries.

If a set of such subtractive filters, which in an ideal manner supply the absorption spectrum of the print colour, shall rest now in negatives, which in the later joint print enable an absolutely colour correct reproduction of the original, the following is still to be mentioned as an essential condition:—

1. The applied plate has to be of uniform sensitiveness in whole visible spectrum.

2. The produced negatives have to be completely uniform character, that is in such a state that grey, respectively white is reproduced uniformly upon all three and appears uniformly covered in all its gradations.

I will take up first requirement (a), because the same is comparatively easier to fulfil. It can be realised best that three exposures, as already mentioned repeatedly, are made upon the same kind of plate, respectively upon the same plate, and that the time of exposure is determined by previous trial and is observed exactly in every light, and that finally the three exposures are simultaneously developed and finished. The importance of this method cannot be debilitated by any arguments. The experience that the same mother emulsion assumes quite a different character by sensitising in different colour matters, and the further experience that this is impossible to develop absolutely uniform three negatives in succession, condition the necessity to go in this direction, if the results obtained are not to remain accidental results. It shall not be denied here that such operators, who make colour exposures all the year around, and work under the same conditions of the same electric lamps, are so familiar with the management of a process developing herefrom that they succeed with a passable average work another way. But only a few gain such practice and experience and the irregular work of most of the reproduction establishments upon this field, above all the not uniform retouching, owing to these circumstances. Not only in my own laboratory but also in one of the most prominent reproduction establishments, I have obtained sufficient proof that, by strictly keeping within the rules, as given by me, the three-colour print will not depend any more upon mere accident, and furnish uniformly good results. The doubts about the application of the same plates for all three filters will not stand the test but one. The one doubt has its origin alone from the non-existence of a sufficiently useful panchromatic plate. But this doubt appears to me to be removed completely by the joint work of Dr. Traut and myself. We possess now, in fact, an actually useful, really ideal yet, but in the above-mentioned direction completely satisfactory panchromatic plate, the ethyl-red plate (perchlor plate). If a bromide of silver gelatine plate is coloured with ethylred, a sensitising band is obtained, which extends from red over the whole visible spectrum with remarkable uniformity so that the plate is equally suitable for the red filter exposures as also for green and blue filter.

Much has been talked about, that also the application of one plate does not assure the possibility of uniform negatives. It has been pointed to the fact, that at different times of development the light impressions behind the red filter change in the covering proportion against those behind the blue filter. These observations are correct, which has not been determined yet, the mistakes originating here are yet so small that practically they have never been felt, at least, I have never been able yet to prove it. Whether with certain colour sensitive plates, sensitised with colour matters from the group of eosins such a mistake appears distinctly, respectively whether the assertion that the action of the yellow rays develops slower as the action of the blue rays with those plates is made with a certain reason, I will leave here undecided. It is a fact that by application of the same panchromatic plate to all three filters, the probability to obtain uniform negative

much greater, as by application of two or three different kinds of plates.

I come now to the influence which the sensitising curve of the plate used must have upon the selection of the filter colours. Upon this field nothing reliable is known yet, and from the observance of certain filters and certain plates such conclusions have been drawn frequently that it is hardly worth while to pay any attention to this matter. It is beyond doubt that the false conclusions and wrong observations, which even have discovered the wonderful expression, that additive and subtractive filters are identical, or at least have no systematic differences, have essentially taken their origin from this source. In fact, the form of the sensitising curve of the applied plate can influence subtractive as well as additive filters in such a way that their correct selection does not appear any more to be subject to any sensible law. An example may explain the aforesaid. I suppose that the subtractive red filter is to be graduated, that it is suitable for a Tetra-Iodide-Eosineplate, as now and then recommended for red filter exposures. The theory demands that by application of a green-shaded three-colour print-blue the filter must be in such a condition that it admits the complete passage of the red and yellow light, while the green light, with reduced intensity towards the blue end of the spectrum, is left to pass through. This ideal blue-print filter would represent with the Tetra-Iodide-Eosineplate rather a green filter than a red filter. The sensitising curve of the Tetra-Iodide-Eosineplate has its maximum, as is known, in the green-yellow, and diminishes from these towards the red end, so that at long exposures it covers still the orange-coloured part of the spectrum, but at short ones it will not reach it. The application of such an ideal subtractive red filter would therefore let its great green sensitiveness come to complete expression upon this plate, while the weak red sensitiveness would remain almost without any action. The negative, which would be produced behind this filter, should result, therefore, in yellow-green completely covered, deep red glass clear, orange-red here and there covered and blue-green and pure green glass clear, because the sensitising curve of the mentioned plate will fall off just as steep towards the red as towards the green. The negative obtained would, therefore, resemble more a defective red-print negative than a correct blue-print negative. Not much different, as with the mentioned plate the equal subtractive red filter would act with the usual red-sensitive plates bought in market. These plates, mostly with cyanin in carefully selected quantity, have a comparatively broad sensitising band, extending from yellow-green to orange, and whose maximum is situated in the yellow part of the spectrum. By application of this plate, the filter mentioned would also result in too large a covering in green. This reflection shows that the subtractive red filter should let so much less green pass through, and should be so much more removed from the theoretically required and by the print colour determined colour-selection, the more unfavourable the sensitising proportion is between red and green upon the applied plate. The most complete panchromatic plate so far produced, the ethyl-red plate, would also, by using an ideal red filter of subtractive kind, produce a false result. The sensitising curves of these here also, beginning in the red end of the spectrum, then pass to yellow, but remains there, if small waves are not taken into consideration, until to blue in equal light. The consequence is that, by using a theoretically correct subtractive red filter, the yellow and green action in opposition to the reduction would come out too strong, and that specially deep red tones in the negative would obtain too weak a covering, because, with consideration to shades containing essentially yellow and green, their time of exposure would be too short. If a subtractive red filter should be correct in action for such a plate, its absorption must be from red towards the refractive end of the spectrum must always fall off yet proportionally pretty steep. At correct representa-

tion the filter approaches, therefore, such a one, which admits the passage of all red to about the middle between C and D, falls off pretty steep to D, and leaves a weak light action to beyond D.

Now we come to the print colour. It is clear, that the selection of the three print colours has to be in a certain relation to the filters, and that, therefore, the filters have to undergo changes, if the shade of the print-colour changes. This is a requirement, as print-colour and filter have to be supplementary, that is: that the light reflected, respectively passed light, has to make up to a complete spectrum. For instance, if the print-blue is taken very pure and proportionately of a violet shade, the red filter has to possess a weaker absorption in green, as when the print-colour is of a greener shade. It is the same with the other filters. Further, the correctness of the reproduction of the colours and the brilliancy of tones will also depend upon the purity of the print-colour, and the observations of Hübl, that in the joint-print colours can never appear which are outside of the complementary colour-circle of the three print-colours, is very true. Still, the consideration of print-colours seems rather subordinate; my view of the matter is that it is more correct to discover such print-colours to a ready set of part-pictures, from which the best results will be had, than to find out to a given set of print-colours the best filters. The difficulty of the latter way is apparent, although the theoretical possibility to do so cannot be denied, and this way, at first look, might appear to be the most rational and sensible. But I believe that, in spite of this, one will not succeed to graduate the filter after the print-colours without leaving a wide space to chance, because in the print (full print) of the three print-colours the accidental saturation of the print plays an unproportionally great part in the result. Therefore, it appears to me conformable to the purpose to cut the filters only in so far in accordance with the print-colour, as this comes in question with the general selection, and according to the absorption of the same; but the highest completeness of the print to vary by small variations, particularly in the composition of the blue-print colour. Thus, as the blue-print colour is the most impure of the three-print colours, the strongest technical effect can evidently be reached by graduation into more violet or green. I have repeatedly heard the question asked whether this kind of print process exercises some influence upon the modes of working respectively, whether it is perhaps necessary to vary the filters, according to whether lichtdruck, chromegum-print, combined carbon-print, etc., is selected as positive process, but must say that I cannot see any reason for such a rule in the nature of things, and that according to my idea it is quite indifferent, at least for the selection of the filters, whether the part-pictures which originated are afterwards to be reproduced by Selle's process, or by way of the gum-print, ozotypy, lichtdruck, or in the pigment process. From the foregoing so much can be seen with certainty that it is an impossibility to give definite formulas and prescriptions for the three filters of a three-colour print, and that every information of certain mixture proportions of colour-matters and their concentrations can have only reference to certain single cases, to cases where the exposure-plate is considered as established and settled, and whereby is supposed that the sensitising curve of the same is always exactly the same. Even under these circumstances the filters may require a small modification if the absorption of the light within the applied objective is not considered as disappearingly small, and if the same strikes certain colours, as it is actually almost always the case. I have already communicated before that the proportions of exposure-time of equal filters by use of the same plates, or by application of different objectives, can be completely different, showing that the construction of the objective cannot be without influence upon the filter-colour. This

influence, of course, may be disappearingly small in comparison with other filters.

In the following I will speak now about the production of the filters, specially with consideration of obtaining transparent layers, whereby care must also be had that the time of exposure-proportions do not become too unfavourable ones—that is, that the exposure-times do not deviate too much from each other. About the technical part of the production of the filters generally I have published already some details. The manufacture of filters is by no means an easy work, and for those who do not care about making a speciality of it, it is advisable to purchase them from the dealer.

The dry filters want to be used as close as possible in front of the plates, because, even carefully produced, optically plano parallel ground plates give during coating with coloured gelatine solutions tension-appearances, which would deteriorate the optical pictures when two of such plates cemented together should find application in front of the objective. But ordinary plate-glass furnishes a good material for filters in front of the plate whose changing with the usual multiplying holder can be effected with the greatest facility. For the production of the filter serve from 8 to 10 per cent. solutions of gelatine as clear as possible, suitably coloured, in measured quantities, and spread upon the plate after the same has previously been thoroughly cleaned and levelled. A great number of colours have the property to influence the drying of the gelatine coating in a peculiar manner. Very frequently it is found that the film, after drying, has become scarred and rough, that the colour matter secretes in stripy formations, or crystallises on the edges of the plate. It is also found that some blue colour-matters make the gelatine so brittle that the film will crack off from the glass after drying. It is very conformable to the purpose to compose the filters, at least the red and green filters, in such a way that two colour-matter solutions are used, which, pressed upon two glass plates, are cemented together afterwards. If the colour-matter solutions are selected in such a way that the absorption-spectrum of one colour-matter is as much as possible towards the blue end, the absorption-spectrum of the other towards the red end, one obtains, at least with the green filter, whose production, of course, makes the greatest difficulties, a very estimable possibility of the graduation of the filter-colours, which an exact cutting-off of the light band allowed to pass through.

1. THE RED FILTER.

The red filter, which furnishes the blue-print plate, is in so far difficult to produce, as the time of exposure depends essentially upon the selection of the red colour-matter. The numerous colour-matters which are at disposal are reduced to a small actually useful number, which admit the passage of sufficient quantities of red light, and permit, in spite of sufficient strength of the red filter, comparatively very short exposures. The—according to their absorptions—very well applicable azo-colour-matters come less into consideration for portrait views. The most suitable bodies are found in the class of the eosines, and amongst them is the rose bengale, by far the most suitable. Rose bengale shows in the given part of the spectrum in somewhat concentrated solution, very broad, sharp absorption stripes, which, according to thickness of the colour-coating, permit towards red any boundary position within certain end values. If a filter is flowed with rose bengale, it has to be combined with a filter which absorbs blue and blue-green, that a red filter of correct character will originate. The colour-coating of the rose bengale filter is thereby to be selected, so that the filter in dry condition will let light through to wave-length 500. In wet condition the absorption-spectrum of the filter gives no support, as during drying the absorption stripes will be displaced to such a degree as the refraction and diffusion index of the gelatine film rises with the evaporation of the water. As a medium quantity for the production of

a red filter, about 1.5 ccm. of a two per cent. solution of rose bengale in water to 18 to 20 ccm. gelatine solution, are to be considered, and of this mixture about 9 to 10 ccm. belong to plate surface of 80 sq. cm. If a plate so produced is combined with a sufficiently thick covering-plate, coloured with a yellow colour-matter, which plate can be produced by colouring a gelatine solution yellow with a 4 per cent. tartrazin solution, an extremely quick-working, well-closing red filter is obtained, which for the ethyl-red plate shows about the desirable position in the absorption.

2. THE GREEN FILTER.

The greatest difficulties and the greatest insecurity in result offers the green filter, which serves for the production of the red print. From the exact fitting of the same to the exposure plate depends in first line the result of the work of the three-colour print, and an incorrectly-graduated green filter may cause just as great defects in the colour-reproduction as the most defective exposures. The ruling points in the production of the green filter refer essentially to the passage of light towards the violet end of the spectrum, while small deviations in the transparency towards yellow are apparently without influence to the result. When the green filter absorbs the blue-green too strong, red will print into all dark-green shades, and the consequence is naturally a contamination of the dark and thereby still pure and illuminating green tones. When, however, the stop towards the blue end of the spectrum is too uncertain, respectively the zone admitting the passage is too long towards this side, it may happen that the finished print picture turns out to be too green-shaded, and that special depths possess an extremely disturbing, troublesome tone of green-blue colour, preventing the forming of a correct black. At all events, the latter defect is more scarce than the former and it may well be said that most of the retouches in the three-colour print are effected by too strong a green filter. For the graduation of the green filter, the difference of sensitiveness between green and blue respectively, the sensitising curve of the plate plays of course the greatest part. Almost all green sensitive plates were distinguished by showing in the blue-green part of the spectrum a minimum of action, and therefore, here, therefore, let us miss the necessary covering, which was just the source of the defectiveness of the red-print plate.

The ethyl-red plate behaves in this regard much better. It possesses in the blue-green part of the spectrum no minimum, as its sensitiveness curve runs pretty straight in this direction, and the sensitiveness band, which originated through sensitising, joins directly to the sensitising band of the mother emulsion. Suitable green filters can be made particularly by application of brilliant acid green, to which are added more or less large quantities of a yellow colour-matter—for instance tartrazin—according to that in the blue part of the spectrum desired stop. If this green filter is selected corresponding light, to secure the necessary transparency in blue-green, most of the green colour-matters show a tendency of light passage of the green filter for the extremest red. This is apt to frighten beginners, and make them believe that this passage of red had to disturb the action of the green filter considerably, and would explain the observed deficient action of the same. There is a number of green-colour matters which do not possess this tendency to red light passage to such a degree as the brilliant acid green. But there is no advantage connected with this application, because the sensitiveness of dry plates reaches never by any means with the short green filter exposure to the infract zone, which is not cut off by the green filter. For this reason it is therefore pretty indifferent if brilliant acid green or one of those colour-matters is selected which close better red. I recommend the former colour-matter, because it furnishes smoothly-drying and regular layers, and does not make the gelatine too brittle. The shade of the brilliant acid green is of little influence. Shade VI. B. corresponds, perhaps, be-

the ethyl-red plate, and it is recommendable, to take brilliant acid green solution so strong, that for 6 cm. square solution for 80 sq.cm. plate surface, 1.6 cm. brilliant green solution 1:100 are selected. To this solution are added 4 to 8 drops of a tartrazin solution, 1:25, and a stop is thereby obtained in the violet and sufficient reduction of the blue.

3. THE BLUE FILTER.

The production of the blue filter is less important. All that is required of the same is that at least with strong blue-green sensitive plates a sharp boundary towards the green part of the spectrum is present. The light is to pass through at most wave-length 480; on the other hand, it is desired for the reproduction of the deep red tones in the original that the blue filter permits the passage of the red of the spectrum, still within the field of action of the plate in question pretty unimpaired. The application of a violet colour-matter is therefore advisable whose concentration towards these points of view has simply to be chosen. For portraits the correct reproduction of very deep red tones is not of so much importance. But a red passage of the blue filter will even here do no harm. To 13 cm. gelatine solution for a plate-size of 80 sq.cm. is recommended an addition of 2 cm. new Victoria blue and 2 cm. of methyl-violet solution 1:250. But this proportionately very light colour-matter disc has the inconvenience for portrait-views that the time of exposure for the same is extraordinarily short. It may, therefore, be recommended to reduce the strong action of this filter by reducing the blue part of the spectrum correspondingly in combination with a yellow disc. For this the blue filter is covered with an extremely thin tartrazin disc, which is so adjusted by tests that the blue filter gives a convenient time of exposure. For ethyl-red plates a very thin covering disc is sufficient to obtain equal exposures for red and blue. This is for portrait views, the most agreeable to avoid small mistakes in the time of exposure, which are also very disturbing with the blue filter plate, and that for blue and red equal exposures are reached, while green will come to an essentially shorter exposure. A reducing of the green filter to likewise equal exposure is very difficult to execute without considerably disturbing the curve of passage. The covering disc, which is required for the blue filter, should contain about 5 to 6 drops of tartrazin solution, 1:25 to about 120 cm. gelatine.

About the technical construction of the afore-described filter have repeatedly made some publications. Faultless filters of this kind to produce is not so easy. Even by the application of the here-described colour-matters, if the work is not done in localities free from dust, and one does not possess experience, mistakes will occur. By irregular drying of the film a zone formation in the filter will frequently take place, and well-dried filters are oftentimes ruined during cementing with Canada balsam. The utmost care and use of suitable cementing material, as well as careful observation of the cement temperature and careful after-heating of the cemented plate, secure, however, to the skilful operator a good result.

During heating of the filter before connecting, as well as during connecting, every deviation of temperature should be avoided as much as possible, and the durability depends essentially upon the height of the applied temperature and the duration of after-drying by artificial heat. General prescriptions or directions cannot be given here, because the work will change according to the balsam used, and hard balsams, high temperature and short heating, soft balsams, low temperature and prolonged heating, require. The cemented filter should not be too thin, and possess sufficiently hardened balsam layers, so that ordinary room temperature they just can be moved a little. After the edges are thoroughly dry they are mounted with strips of gummed paper. Some express fear of the bleaching of the filters. This will not happen providing they are not exposed to the sun for hours. I possess a red filter which has done service for two years, and the same has not changed yet in the least way.

PROFESSOR DR. A. MIETHE.

FOREIGN NOTES AND NEWS.

REVERSAL.—It is somewhat generally accepted that reversal of the image with gelatino-bromide plates is accompanied by a tanning effect upon the gelatine; in fact, it is assumed by some writers that this tanning action is so great that it prevents the developer from penetrating the film. Dr. Lüppler-Cramer recently stated that he found that a dry plate exposed for twenty-four hours to sunlight was as readily fixed as an unexposed plate, which would not be the case if the tanning effect was produced. Now Dr. Büchner, of Darmstadt, has confirmed this statement and records the fact that plates exposed from six hours to three days showed no difference in the rate of fixing to an unexposed plate. Another statement which has also been connected with this subject is that the reversed parts showed a strong relief, but this also Dr. Büchner has been unable to detect.

ALBUMEN SOLUTION FOR BLOCK WORK.—Herr Franz Novak has suggested the following method for preparing a solution of albumen for photo-mechanical work, and states that it will keep for a month and give excellent results:—140 g. of dried albumen are mixed in a mortar with 980 c.c. of water, and 2 g. of crystallised carbolic acid added; the whole is well stirred, and left for two or three hours to soften, and it should then be rubbed up with a pestle till complete solution is effected and then filtered through cotton wool in a loosely (?) stoppered bottle.

DURABLE CARBON TISSUE.—Professor Kessler has been testing the suggestion of Dr. Namias and Mr. Bennett, that the addition of ammonium citrate to the sensitising bath for carbon work not only increases the sensitiveness but the keeping properties also, and has found the tissue sensitised with this addition to the bichromate bath gives perfect prints, even after the lapse of five weeks, and that prints, kept for two weeks after exposure have also given perfect results, and without the slightest sign of the film becoming entirely insoluble. Namias suggested also the addition of the acetates, oxalates, succinates, lactates, and tartrates for the same purpose.

ANOTHER THREE-COLOUR PORTRAIT.—In the current number of the "Photographische Correspondenz" there appears a half-tone supplement, a portrait study from negatives taken in the studio on a cloudy day in January, with a Unar lens, working at F.7, the exposures being one second for the blue, three seconds for the green, and two seconds for the red, on a plate colour-sensitised by bathing with pinachrome, one of the new isocyanines prepared by Meister, Lucius, and Brünini, with the screens suggested by Dr. König of the same firm. In connection with the use of these new cyanines it is interesting to note that, up to the present, their full effect is only obtainable by bathing prepared plates, and that, as pointed out by Dr. Eder, modifications of the emulsion must be made, though in what direction is not stated, ere satisfactory results can be obtained, by adding the dye to the emulsion. It has also been proved that only some commercial plates can be successfully colour-sensitised by these dyes, a fact which obviously also depends upon the constitution of the emulsion. In respect to this it may be noted that a large proportion of iodide or the presence of free bromide usually has a prejudicial effect upon the action of various dyes.

WASHING DIPPED ORTHOCHROMATIC PLATES BEFORE DRYING.—Dr. J. M. Eder writes in the "Photographische Correspondenz" under this heading, that it has been recently recommended to revise the surface before drying orthochromatic plates, which

have been prepared by immersion in a solution of ethyl red, orthochrom T, pinachrom, etc. By this superficial washing the plates are cleared of superfluous dye, which would be retained if they were immediately set up to dry. The tenacity with which gelatino-bromide of silver retained the dye used as a sensitiser, ensures sufficient being kept in the film. Apart from the greater purity and clearness of such plates, the typical behaviour of dipped plates towards the spectrum is not changed by the operation of washing. It is not without interest that this washing process was mentioned twenty-two years ago by Attout, known as Tailfer and Clayton. They recommended in their French patent specification of December 13, 1882, Patent No. 152,615, not only the staining of the gelatino-bromide of silver in the bulk, for the preparation of eosine plates, but likewise the dipping of the dry plate in a solution of eosine, and prescribed washing the plate with water when it was taken from the sensitising solution. Bothamley, in 1888, also recommended the dipping of the plate in an aqueous solution of erythrosine and the removal of the superfluous dye, by washing, before drying the plate. He knew the Attout-Tailfer and Clayton process and studied it, but he afterwards relinquished the rinsing of the stained plate as a simplification, and then it was generally abandoned. Subsequently Ives, Debenham, and Hinterberger tried with success pouring upon the plate an alcoholic solution of cyanine. The plates were then immersed in water, and exposed wet. We have now, with the new isocyanines, returned to the original procedure, and rinse the stained plates with water, subsequently drying them. This procedure has been recommended by Professor Miethe and Dr. König, and it is always used at the Vienna Technical School for the preparation of pinachrom dipped plates.

PLATINUM TONING.—Recently Professor Namias suggested for platinum toning matt printing-out papers, that a bath composed of oxalic and hydrochloric acid in conjunction with the chloroplatinite was superior to all others as less likely to cause the yellow stains too often met with, and that it gave better whites. Namias' actual formula was:—Potassium chloroplatinite, 1 g.; pure hydrochloric acid, 5 c.c.; oxalic acid, 10 g.; distilled water, 1,000 c.c. Recent comparative experiments with this against the well-known phosphoric bath, made at the K.K. Lehr- und Versuchsanstalt at Vienna, have proved that the latter tones quicker, and the bath can be more exhausted, thus saving platinum, than Namias' bath. The phosphoric bath is:—Potassium chloroplatinite, 1.6 g.; phosphoric acid, sp. gr. 1.12, 25 c.c.; distilled water, 1,000 c.c. Both baths give the same tones.

TELEGRAPHING Pictures and Handwriting.—In an address recently delivered at the Berlin Urania, Prof. Cerebotani presented a telegraphic apparatus for transmitting any kind of handwriting, drawing, tracings of photographs, etc. The fundamental principle is identical with the principle employed, for instance, by Elisha Gray, the novel feature being a highly sensitive system of electro-magnets. In the case of the drawing pencil of the transmitter being moved upward in an oblique direction, the line obtained in the receiving apparatus of previously-invented systems is a broken one. In Cerebotani's system, the electro-magnets are so sensitive as to produce nearly straight lines, even in the case of their being excited by extremely small currents. The telegraphic transmission of pictures and handwriting, as obtained by means of his apparatus, is therefore much clearer and truer than in the case of any previous apparatus. Some samples produced by Cerebotani were transmitted on the telegraph lines from Munich to Augsburg, from Milan to Turin, and finally from Berlin to Munich. A picture transmitted some weeks ago from Berlin to Munich over a distance of 403 miles is said to be the finest specimen of telegraphic transmission ever obtained in this direction.

THE DETECTION OF CHLORIDES IN THE PRESENCE OF BROMIDES.

THE only difficulty concerning halogen salts in general qualitative analysis is the detection of a small quantity of a chloride in the presence of a bromide. The methods suggested consist, as a rule (write Chapman Jones in "The Chemical News"), either in eliminating bromine and then testing for the chlorine, or in precipitating silver salts and dissolving out the silver chloride. In the first the separation is rarely if ever sharp, either a little bromine is behind or a little chlorine is lost, and it is therefore impossible to say whether or not a little chlorine is present. In the other method there is no loss, and this is a very considerable advantage, but in both presence and the absence of a little chlorine a positive result is generally obtained, and it remains to discover whether a slight turbidity, produced on re-precipitation from the extract, is due to silver chloride or bromide. With sufficient practice and care this is not impossible when using the reagents that have already been proposed, but a distinct difference between the two salts is very desirable. During the last year or two I have used ammonium bicarbonate for this purpose with much satisfaction. A saturated aqueous solution of this has the advantage that it is more definite than a dilute solution of ammonia or a solution of any other carbonate of ammonia, and that it shows a greater difference in its behaviour to the two silver salts. Mr. R. H. Beckett, B.Sc., of this college, has carefully confirmed the following statements, using the precipitated silver salts in as many cases as possible the condition in which they generally occur. If a saturated solution of ammonium bicarbonate is poured over a silver chloride on a filter paper, the extract will give a distinct turbidity on acidification with nitric acid. Silver bromide similarly treated gives no turbidity. By allowing the silver salts to remain in contact with the reagent for a few minutes with occasional agitation, the chloride will give a greater turbidity on acidification, while the turbidity of the bromide may be continued sometimes even for half an hour before it begins to give a positive result. If a turbidity is obtained on acidification of the extract, and it is doubtful whether it is due to silver chloride or bromide, its identity may be established in the following way:—The turbid liquid is divided into two parts; to one is added a slight excess of the bicarbonate solution and to the other an equal quantity of water. If the turbidity is due to silver chloride, the ammonium salt will re-dissolve it in a few seconds. If it is due to silver bromide it will remain unaffected for several minutes, if not an hour or more. The part diluted with water is for comparison with the other, as it is difficult to bear in mind the appearance of a turbid liquid, and to duly allow for its dilution. It is desirable that the ammonium bicarbonate solution be not old, or it will probably have lost some carbonic acid. A boiling solution of sesquicarbonate of ammonia has been used before for dissolving out silver chloride from the bromide, but in this case some of the bromide is always dissolved.

URANIUM is one of the rare metals for which there is a limited demand. The present world's consumption amounts annually to about 300 tons of uranium ore, yielding from 3 to 13 per cent. of the metal. For several years Colorado has supplied the United States output, nearly all of which goes to Europe. France, England and Germany are the principal markets. Uranium is a hard, very heavy (9.184), moderately malleable metal; it resembles nickel in colour, and has the colour of nickel. At ordinary temperatures it is not affected by air or water; at red-heat, however, the surface oxidises. The chief ore of uranium is the oxide, called pitchblende or uraninite. It occurs also as the phosphate and arsenate. The ores are found in Gilpin and other counties of Colorado; in Cornwall, England; and in Saxony, Germany. Buyers of the ore generally pay from 15 dols. to 20 dols. per unit, according to the percentage of uranium contained. Until recently, uranium salts were used chiefly as a pigment in painting on porcelain, in photography, and as a colouring ingredient in glass manufacture. It is now being used experimentally in the manufacture of alloys of iron and of aluminium. Uranium increases the hardness and elasticity of steel, also the hardness of aluminium, but this use has not yet become sufficiently important to cause an increased demand for the metal.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

NINETEENTH ANNUAL MEETING: DERBY, JULY 11 to 16, 1904.

President.—G. Herbert Strutt, Esq.

The meetings and exhibition of apparatus, pictures, etc., will be held in the Mechanics' Institute, The Wardwick.

President for the year.—G. Herbert Strutt, Esq., President of the Derby Photographic Society, Sheriff of the County, etc.

Retiring President.—Sir Robert Pullar.

Past Presidents.—J. Traill Taylor, Andrew Pringle, *C. H. Hambley, *George Davison, William Bedford, George Mason, Sir Edward Grubb, A. Haddon, H. P. Robinson, *F. P. Cembrano, John Stuart, *William Crooke, *Thomas Bedding, Sir William Herschel, Bart., Sir Robert S. Ball. *Marked thus are Vice-Presidents.

Members of the Council.—H. Walter Barnett, London; Harold Baker, Birmingham; G. B. Bainbridge, Newcastle-on-Tyne; Godfrey Angley, Leeds; Henry Coates, Perth; W. J. Croall, Edinburgh; R. Dallmeyer, London; W. E. Dunmore, London; Alfred Ellis, London; S. H. Fry, London; F. H. Gandy, Derby; J. Pattison Gibson, Hexham; T. K. Grant, London; Dr. E. Collier Green, Derby; H. M. Hastings, London; E. J. Humphrey, London; T. Kingworth, London; Martin Jaolette, London; C. Barrow Keene, Derby; Sydney Keith, Hounslow; G. Trevelyan Lee, Derby; C. Ips Lucas, London; Percy Lund, Bradford; Colonel Lysaght, London; J. W. Marchant, London; Bendle W. Moore, Derby; F. Mowll, Liverpool; Rev. T. Perkins, Blandford; Arthur Westley, Birkenhead; Ralph Robinson, Redhill; P. R. Salmon, London; F. H. Sanderson, Cambridge; A. Seaman, Chesterfield; Alexander Tate, Belfast; W. Taylor, Leicester; Dr. J. K. Tulloch, Leeds; J. H. Walker, Leeds; E. J. Wall, London; H. Snowden Ward, London; Major-General J. Waterhouse, I.S.C., London; B. Webber, London; G. Watmough Webster, Chester; J. B. B. ellington, Elstree; A. Werner, Dublin. Messrs. G. W. Norton (Oxford), H. A. Chapman (of Cambridge), and Alex. M. Rodger (Perth), are by Rule XII. *ex officio* Members of Council, for one, two, and three years respectively.

Vice-Presidents are by Rule X. Members of Council *ex officio*.

Trustees.—Samuel Blatchford Webber and Frederick Albert Edge.

Hon. General Secretary and Treasurer.—F. A. Bridge, East Lodge, Aston-lane, London, N.E.

Reception Committee.—Alderman G. Herbert Strutt, J.P. (Chairman); his Grace the Duke of Devonshire, K.G.; his Grace the Duke Rutland; his Worship the Mayor of Derby (Councillor Cornelius Ham); Alderman Sir Henry H. Bemrose, J.P.; Sir Clement Bowring, Kt., Park Grange, Derby; Alderman Sir Thomas Roe, M.P.; Alderman E. T. Ann, J.P.; Councillor H. Arnold-Bemrose, M.A., J.P.; Rev. C. F. L. Barnwell, Stramshall, Uttoxeter; J. C. Cade, J.P., Spondon; W. G. Constable, Esq., B.A., B.Sc.; Councillor W. Gandy, J.P.; Alderman Edgar Horne, J.P.; N. J. Hughes-Jones, Esq., Clerk to the County Council; Councillor R. Laurie, J.P.; G. Trevelyan Lee, Esq., Town Clerk; J. C. Lee, Esq., Hounslow; Gilson Martin, Esq., J.P., Chatsworth; G. W. Peach, J.P., Langley Hall; F. W. Shurlock, Esq., Principal of the Technical College; J. H. Topham, Esq., Morley Hall; P. K. Tollit, Esq., Head Master, Derby School; John Ward, Esq., Borough Surveyor; E. W. Wells, Esq., Assistant General Manager, Midland Railway; Alderman W. W. Winter; the Officers of the Derby Photographic Society.

Local Executive Committee.—Alderman G. Herbert Strutt, J.P. (Chairman); Mr. A. H. Bennett, Mr. J. B. Brooks, Mr. J. B. Cope, Mr. H. G. W. Dawson, Mr. S. Finney, Mr. F. H. Gandy, Mr. E. Collier Green, Mr. C. B. Keene, Mr. G. Trevelyan Lee, Mr. B. W. Moore, Mr. T. A. Scott, Mr. F. G. Smith, Mr. G. Walker, Mr. F. Willatt, Mr. G. H. Widdows.

Dinner and Entertainment Committee.—Mr. H. G. W. Dawson, Mr. F. H. Gandy, Mr. E. Collier Green, Mr. C. B. Keene, Mr. B. W. Moore, Mr. F. G. Smith.

Selecting Committee (Members' Unframed Print Exhibitions).—Mr. Harold Baker, Mr. E. Collier Green, Mr. C. Barrow Keene, Mr. J. Porritt.

Hon. Local Secretary.—W. Crowther, Corporation Art Gallery, Derby.

NOTICE TO MEMBERS.

On Monday, July 11, the Hon. Secretaries will attend all day from 10 a.m. at the Mechanics' Institute. Members are requested to report themselves as early as possible, receive their badges of membership, and secure tickets for the excursions.

Signature Book.—It is desirable that members, immediately on arrival, should enter their names, full addresses, and where staying in Derby, in the signature book at the Mechanics' Institute.

Plan of Derby.—A plan of the central portion of the town will be found on inset at front of book. The Mechanics' Institute, where the conversazione, evening meetings, and exhibitions will be held, is situated in the Wardwick, and is numbered 1 on the plan. Trams between the Midland Railway Station and the Market-place, every few minutes. Fare, one penny.

Excursions.—Members should obtain tickets for these as early as possible, in order that adequate provision may be made for their comfort and convenience. With regard to Tuesday's excursion it is absolutely necessary that members wishing to go, should write to the Hon. Secretaries, Photographic Convention, Mechanics' Institute, Derby, so that the letter is delivered not later than first post on Monday, July 11.

Permission to Photograph.—The Local Committee anticipates no difficulty in obtaining the fullest permission to photograph at all the places to be visited.

Notice Boards.—Notice boards will be placed in the meeting room. Members are requested to consult these daily.

Annual Dinner and Smoking Concert.—The annual dinner and smoking concert, at which ladies are welcomed, will be held at the Royal Hotel, Victoria-street. (No. 4 on plan.) Owing to the inconvenience caused by members not obtaining their dinner tickets until the last moment, it has been decided to close the list at eleven o'clock on Wednesday morning, July 13.

EXHIBITIONS.

During Convention Week an Exhibition of Apparatus, Pictures, etc., will be held in the Albert Hall of the Mechanics' Institute. There will also be an Exhibition of Unframed Prints, the work of Members of the Convention. A special section will be reserved for pictures taken at the Perth meeting (1903). An Exhibition of Professional Work, by Members of the Professional Photographers' Association, will be open during the week at the Corporation Art Gallery, adjoining the Mechanics' Institute. Admission free to Members of Convention.

Special Notice.—The times of departure of trains on the excursions have been given as correctly as could be ascertained at the time of going to press. It is not expected that there will be any alteration; but in any case the correct times will be stated on the Excursion Coupons.

The Evening Meetings and Excursions are for Members of Convention only.

RAILWAY ARRANGEMENTS.

Midland Railway.—Long-date week-end tickets, at cheap fares, are obtainable at the principal Midland Railway Stations, any Friday or Saturday, available to return by any train on any day (the Sunday immediately following excepted) up to and including the following Monday week. These tickets are issued to Matlock. Return fare—Third class, 17s.; first class, 30s.

Ordinary tourist tickets are issued from London to Matlock (available at Derby) on any day and by any train. Third class, 21s.; first class, 38s. 4d. Tourist tickets, at reduced fares, are also issued to Matlock and Buxton, from the principal stations on the following railways:—Midland, Great Central, Great Eastern, North British, North-Eastern, North Staffordshire, Hull and Barnsley, and London, Brighton, and South Coast.

For further particulars, dates of special excursions, etc., members should consult the bills at the principal railway stations in their vicinity.

ARRANGEMENTS.

Monday, July 11.—For the benefit of those members of Conven-

tion who will be in Derby previous to or early on Monday, members of the Local Committee will attend at the Mechanics' Institute, to act as guides, and will arrange for short excursions as may be required. For particulars see notice boards.

Conversazione.—The opening conversazione will take place in the Albert Hall of the Mechanics' Institute. At 7.30 there will be an official reception by his Worship the Mayor (Councillor Cornelius Boam), the members of the Corporation, and other public bodies. At eight o'clock the Convention will be declared open, and the President, Mr. George Herbert Strutt, will deliver his inaugural address, after which the exhibition of photographic apparatus, pictures, etc., will be on view; musical promenade, refreshments, etc.

Tuesday, July 12.—Excursion to Dovedale—Leaders: Mr. J. C. Lee (Ashbourne) and Mr. T. A. Scotton (Derby). 9.0, conveyances leave the Strand, Derby (back of Art Gallery); 10.45, arrive at Ashbourne; 11.45, leave Ashbourne; 1.0, lunch at Peveril Hotel; 5.0, leave for Ashbourne; 6.0, tea at Ashbourne; 7.0, leave Ashbourne, arriving at Derby about 8.45. Tickets, including drive, luncheon, and tea, 7s. 6d.

Dark Rooms at Ashbourne.—Bull, R. and R., Victoria Studio; Lee, J. C., Market-place.

There will be no meeting at the Convention Rooms on this evening.

Wednesday, July 13.—The annual general meeting and election of the new Council will take place at the Convention Rooms at ten o'clock. The new Council will meet at eleven o'clock. The time and place at which the official group of the Members of Convention will be taken will be duly announced on the notice boards. In the afternoon, at 2.30, the President, Alderman G. Herbert Strutt, J.P., and Mrs. Strutt will give a garden party and reception at Bridge Hill, Belper. Special trains will be arranged for the occasion. The annual dinner and smoking concert will be held at the Royal Hotel, Victoria-street, at 7 p.m. Lady members are cordially invited to be present at the dinner and concert. Tickets (including attendance, but not wine), 5s. 6d.

Thursday, July 14.—Excursion to Hardwick—Leaders: Mr. E. Collier Green and Mr. C. Barrow Keene. 10.5, train leaves Midland Station; 10.53, arrive at Stretton; 11.0, leave Stretton by coach; 12.0, arrive at Hardwick; 1.0, luncheon at Hardwick Hotel; 4.50, leave Hardwick by coach; 5.50, leave Stretton by train; 6.25, arrive at Derby. Tickets, railway, drive, and luncheon, 6s. 6d. At the Mechanics' Institute, at 8.30, a paper by Thomas R. Dallmeyer, Esq., F.R.A.S., on "Telephotography," followed by an exhibition of lantern slides by members of the Derby Photographic Society, under the direction of Dr. E. Collier Green.

Friday, July 15.—Excursion to Chatsworth and Haddon Hall—Leader: Mr. H. H. Bennett. 9.30, train leave Midland Station; 10.20, arrive at Rowsley, and leave by conveyance for Chatsworth; 1.30, leave Chatsworth; 2.0, lunch at Wheat Sheaf Hotel, Baslow; 3.0, leave Baslow, driving via Pilsley and Bakewell to Haddon; 5.15, leave Haddon; 6.30, arrive at Derby. Tickets, railway, drive, and luncheon, 7s. 6d. At the Mechanics' Institute, at 8.30, an unconventional lecture by Thomas Bedding, Esq., F.R.P.S., entitled "The Influence of Photography upon the Modern Stage," followed by a paper by H. Snowden Ward, Esq., F.R.P.S., on "Figures in Landscape," illustrated by lantern slides.

Saturday, July 16.—Short excursions in the neighbourhood, as may be desired—probably to Matlock, Wirksworth, Cromford, etc.

Dark Rooms.—Derby—Bell Hotel, Sadler Gate; County Hotel, St. Mary's Gate; St. James's Hotel, St. James's-street; Municipal Technical College, Green Hill. Also at the following photographic dealers—R. Blaylock, 229, Normanton-road; Derby General Stores, 30A to 33, Victoria-street; Hoare and Son, 8, Osmaston-road; A. Judge, 19, Pear Tree-road; R. Keene, Limited, 24, Iron Gate; F. P. Pemberton, 36, Corn Market, 67, London-road, and 226, Uttoxeter New-road; W. Shepard, 96, Abbey-street.

Hotels, etc.—Bell Hotel, Sadler Gate.—About fifteen beds. Bed, breakfast, and attendance, 6s. 6d. Clarendon Hotel, Station-street.—Eight beds. Bed, breakfast, and attendance, 6s. County Hotel, St. Mary's Gate.—Six beds. Bed, breakfast, and attendance, 5s. Derwent Hotel, London-road.—Six beds. Bed, breakfast, and attendance, 5s. Midland Hotel, adjoining Midland Station.—About thirty

beds. Tariff on application. Royal Hotel, Victoria-street.—thirty beds. Bed, breakfast, and attendance, 6s. 6d. St. James's Hotel, St. James's-street.—About twenty beds. Bed, breakfast, and attendance, 6s. 6d.

Temperance Hotels.—Portland, 19, Midland-road.—Twenty beds. Bed and breakfast, 4s. 6d. Granville, 102-4, London-road.—Bed and breakfast, 4s. Caledonian, 18, Midland-road.—Eight beds and breakfast, 4s. Waverley, 20, Midland-road.—Twenty beds and breakfast, 4s. Grosvenor, 137, London-road.—Six beds and breakfast, 3s. 6d.

Restaurants.—The Cavendish, Corn Market; Cornwell's Midland; Dequies, St. Peter's-street; W. Fletcher, Iron Gate; L. and E. King, St. Peter's-street; Midland Hotel and Railway Station; A. Smith, Victoria-street; H. Ramsden, St. Peter's-street.

Tea Rooms.—W. Fletcher, St. James's-street and Iron Gate; James King, Normanton-road and Wardwick; L. and E. King, Peter's-street; Oriental Cafe, Iron Gate.

Private Apartments.—A list of private apartments, with terms, will be forwarded on application to the Hon. Local Secretary, W. Crowther, Corporation Art Gallery, Derby, to whom all communications on this subject should be addressed.

Please Note.—The Hon. Secretaries cannot undertake the responsibility of engaging apartments. Members desiring such accommodation must communicate direct to the addresses given, and make their own arrangements.

SYNOPSIS OF PROCEEDINGS.

Monday, July 11.—Members of the Local Committee will attend at the Mechanics' Institute to act as guides, and will arrange short morning and afternoon excursions as may be required. Notice boards. At the Albert Hall of the Mechanics' Institute, 7.0, Official reception by his Worship the Mayor (Councillor Cornelius Boam), the members of the Corporation, and other public bodies. At eight o'clock, the President will deliver his inaugural address after which the Exhibition of Photographic Apparatus, Pictures, etc., will be on view. Musical promenade, refreshments, etc.

Tuesday, July 12.—Excursion to Dovedale—Conveyances leave Strand, Derby, 9.0; arriving at Ashbourne, 10.45; leave Ashbourne, 11.45; luncheon at the Peveril Hotel, 1.0; conveyances leave "Peveril" for Ashbourne, 5.0; tea at Ashbourne, 6.0; leave Ashbourne, 7.0; arriving at Derby about 8.45. There will be no meeting on Tuesday evening.

Wednesday, July 13.—At the Mechanics' Institute—The annual general meeting, election of Council, etc., 10.0; meeting of the new Council, 11.0; the official Convention group will be taken by Mr. Barrow Keene. For time and place see notice boards. At Bridge Hill, Belper.—Reception and garden party by the President and Mrs. Strutt, 2.30. At the Royal Hotel.—Annual dinner and smoking concert, 7.0.

Thursday, July 14.—Excursion to Hardwick—Train leaves Midland Station, Derby, 10.5; arriving at Stretton, 10.53; leave Stretton by coach, 11.0; arriving at Hardwick, 12.0; luncheon at the Hardwick Hotel, 1.0; leave Hardwick by coach for Stretton, 4.50; train leaves Stretton, 5.50; arriving at Derby, 6.25. At the Mechanics' Institute.—A paper, by Thomas R. Dallmeyer, Esq., F.R.A.S., on "Telephotography," followed by an exhibition of lantern slides by members of the Derby Photographic Society, 8.30.

Friday, July 15.—Excursion to Chatsworth and Haddon Hall—Train leaves Midland Station, Derby, 9.30; arriving at Rowsley, 10.20; leave Rowsley by coach for Chatsworth, 10.30; leave Chatsworth for Baslow, 1.30; luncheon at the Wheat Sheaf Hotel, Baslow, 2.0; leave Baslow for Haddon Hall, 3.0; leave Haddon, 5.15; leave Bakewell for Derby, 5.23; arriving at Derby, 6.30. At the Mechanics' Institute, 8.30, an unconventional lecture, by Thomas Bedding, Esq., F.R.P.S., entitled "The Influence of Photography upon the Modern Stage." A paper by H. Snowden Ward, Esq., F.R.P.S., on "Figures in Landscape," illustrated by lantern slides.

Saturday, July 16.—Various short excursions to places in and around Derby will be arranged as may be required. Members will be obliged by signifying their wishes to the Hon. Secretaries as early as possible, in order that particulars may be duly posted on the notice boards.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
.....	Croydon Nat. His. and Sc. Soc.	<i>Gum-Bichromate Process.</i> Demonstrated. Mr. J. M. Sellers.
.....	Southampton Camera Club	<i>Helion.</i> Demonstrated. Mr. S. G. Kimber.
.....	Nelson Photographic Society	<i>Platinotype.</i> Demonstrated. Mr. Wm. Sutcliffe.

CROYDON CAMERA CLUB.

May 18.—The intensification and reduction of negatives was dealt with by Mr. J. M. Sellers, in a thoroughly practical and interesting manner. In his opinion, the great majority of negatives could be improved by intensification or reduction, local or otherwise. In no case, however, should either be resorted to without pulling off trial print from the negative it was proposed to operate on. If it was a valuable one, a transparency should be made to guard against accident or failure. Mr. Sellers divided negatives into series of typical, if arbitrary, classes, and proceeded to point out their varying characteristics by diagrams showing the films in section. The varying effects of the different reducers and intensifiers in common use were also well illustrated by a set of prints and graduated slips, from negatives before and after treatment.

In the discussion that followed, Mr. F. W. Hicks said that on several occasions negatives which had been developed, fixed, washed, and intensified under apparently identical conditions did not show equal durability, some in time acquiring markings, whilst others did not do so. Other members narrated their experiences as to the permanency of intensified negatives with the various reagents which, it is almost invariably the case, did not at all accord with one another. One little point mentioned deserves notice. When intensifying with uranium, a number of small circular markings had popped up with annoying frequency, the cause being eventually traced to the ordinary grooved washing rack. The plates being pressed together, and the circulation of water poor, minute air bubbles congregated on the film, and remained there without change of position. Mr. W. H. Smith said he had constructed a washer some years ago, and showed it at the Club, which removed all hypo in twenty minutes, or, at least, its presence failed to show under the usual tests. A washer might be tested by allowing a few drops of milk to enter, and noting when and where the liquid cleared. Mr. F. E. Dunmore said he had recently inspected a washer, which he thought removed the hypo in three minutes precisely, and in answer to a general murmur of incredulity, stated it was a very fine washer indeed. The President, Mr. S. H. Wratten, in reference to intensification with mercuric chloride followed with ammonia, said he had always found it best to use the latter at minimum strength, consistent with a convenient rate of action. Negatives should also be gently wiped with a plectrum of cotton wool. Some water supplies contained a large amount of grit in suspension, this, to a great extent, might be remedied by adjusting a piece of flannel, or other suitable material, over the tap, so as to form a rough filter.

INDECENT Postcards.—Joseph Fullerton, of Camberwell Road, was summoned at the Lambeth Police-court, by Detective Badcock, for wilfully exposing to view in the window of his premises six indecent pictorial postcards. There was a second summons against the defendant, calling upon him to show cause why certain postcards which were seized by the police at his premises should not be destroyed. The defendant said he honestly believed that the cards were not indecent. He had no wish to sell any that were improper. Mr. Hopkins remarked that looking at the cards as a whole, he did not think that any man of good taste or decent feeling could have any doubt as to what was their character. There would be an order for the destruction of the cards, and the defendant would have to pay a penalty of £20.

FORTHCOMING EXHIBITIONS.

June 12-24.—First International Salon in The Hague. Sekretariat Haag, Conrad Kade 65, The Hague, Netherlands.

June-October.—Glasgow Photographic Exhibition. Secretary, Art Gallery and Museum, Kelvingrove, Glasgow.

July 14 to September 30.—Vienna Photographic Society. Secretary, W. Burger, Karmelitergasse 7, Vienna 11.

August 1.—Andover and District Horticultural Society. Photographic Section. Hon. Secretary, W. L. Gradidge, Jubilee House, Andover.

October 1-30.—Berlin International Photographic Exposition. M. Franz Goercke, Berlin W. 62, Maassen-Strasse 32, Germany.

November, 1904. Ilford and District Photographic Society. Hon. sec., W. N. Beal, 155, Thorold Road, Ilford.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 23-26.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-104, West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issott, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

May 31.—Ensign-Vidil. £100 in prizes for negatives on Ensign-Vidil films. Houghtons, Limited, 88-89, High Holborn, London, W.C.

June 30.—"Photographic News" Quarterly. Money prizes, silver and bronze medals for prints. Any subject. "Photographic News," 9, Cecil Court, Charing Cross Road, London, W.C.

June 30.—Kodak. £1,000 in cash prizes for pictures taken on Kodak films and plates, etc. Kodak, Limited, 41-43, Clerkenwell Road, London, E.C.

October 1.—Thornton-Pickard. £100 cash prizes for pictures taken with Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.

October 10.—Luna paper. £240 cash prizes for prints on Luna paper. Lucien Allegre and Co., 59a, New Oxford Street, London, W.C.

October 15.—Belgian Association Lantern Slide Stereogram Competition. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.

October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve pictures. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

December 31.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott and Sons, Limited, Barnet, Herts.

March 15, 1905.—Ilford. £750 in prizes for negatives on Ilford plates. Ilford, Ltd., Ilford, E.

M. GLOVER, Limited.—The above-named Company has been registered with a capital of £3,000 in £1 shares, to carry on the business of photographers, etc., and to acquire the business of limited articles. Director, Mr. John James Thomas Glover. Registered office, 124, Stephen's Green, Dublin.

News and Notes.

No. 1 of the "Optical Lantern and Cinematograph Journal" is to hand. It is well got up, and deals in a business-like manner with the subjects it professes to cater for. It should fill a niche at present unoccupied in the world of journalism.

MESSRS. THOMAS ILLINGWORTH AND CO., LTD., of Willesden Junction, have sent us their new price list of picture-frame mouldings. Many new and choice designs in frames are included, and every photographic exhibitor should send for a copy.

A catalogue of second-hand and shop-soiled photographic goods has been sent us by the Tella Camera Co., 110, Shaftesbury Avenue, London, W. Most of the apparatus listed therein is in new condition and all is guaranteed in thorough repair. A postcard addressed as above will secure a copy.

We have received a copy of Messrs. Adams and Co.'s new price list of hand cameras and accessories. It gives full particulars of the Keni, the Videx, the Locka, the Club, the Adams changing boxes, and other apparatus which this firm has made popular. A line to 26, Charing Cross Road, London, W.C., will procure a copy.

We can recommend to the notice of the photographer who intends going South for his holidays this year, the illustrated guide issued by the London and South Western Railway Company. It contains full particulars, etc., of every place of interest in England likely to be sought by the holiday maker south of London and west of Portsmouth. The seaside resorts and holiday haunts in Normandy and Brittany are also served by this line.

We have received specimens of "The Gaze" photo or picture holder, made by Mr. Tress, of 33, Oxford Street, London, W. The holder is a neat little device, consisting of four celluloid "corners" held together by elastic cord and kept in place by a brass strut. The "corners" are slipped over the corners of the photo, the elastics hold them firmly in position, and the strut at back can then be placed at a convenient angle and the whole stood up for show purposes. They should have a good sale among professional photographers who make a display of unframed prints in the window.

The latest edition of Lizars' photographic catalogue is well up to the high standard set by its predecessors. It is a very complete compendium of everything photographic, and includes also full details of all the celebrated "Challenge" cameras, etc., made by J. Lizars. A useful feature embodied in previous editions, in the shape of a section devoted to formulæ and hints for photographers, is still retained. The illustrations are of high merit, and show the adaptability of the firm's products to varying conditions. Copies will be sent free to any applicant, on receipt of request addressed to 20, High Holborn, London, W.C., or 101 and 107, Buchanan Street, Glasgow.

The Formation of Radium.—Evidence is accumulating to show that helium may be produced as a result of the disintegration of the radium atom, and Professor Rutherford has suggested that radium itself originates from uranium. Mr. W. C. D. Whetham remarks, in a letter to "Nature," that in the case of all samples of uranium oxides and salts which he has examined he has found greater amounts of radium emanation from old specimens than from recently prepared specimens of the same compounds. If it should be found by other investigators that this is so in all cases, strong presumptive evidence would be furnished that radium is formed by the disintegration of uranium.

PROF. H. DU BOIS and **H. RUBENS** eleven years ago investigated the polarisation of non-diffracted infra-red rays through narrow wire gratings, with a view to obtaining simpler conditions than in the case of visible short-wave rays. In fact, in the infra-red region of the spectrum, there is much less dependency on the molecular own vibrations of the substance, which so influences the behaviour of the visible spectrum that a confirmation of the electro-magnetical theory meets with the highest difficulties. Now, in a recent paper read before the German Physical Society, Berlin, the experimenters extend their researches to much higher wave lengths, using the so-called residual rays (Reststrahlen) from fluorspar (mean wave length 25.5μ) and from rock salt (mean wave length 51.2μ), the mantle of an Auer burner serving as the illuminant. After being polarised through a reflection on glass or quartz plates under the

angle of polarisation, the rays were reflected from four fluorite five-rock-salt surfaces, whence a concave mirror concentrated on a thermic battery. From the results of these experiments, inferred that the transmissibility of rays will augment for increasing wave lengths. The increase of the unpolarised rays is particularly remarkable, being fairly well in accord with the theoretical value.

Hove Camera Club.—The annual general meeting of this prosperous southern society was held at the Town Hall, Hove, on Tuesday May 17. The report presented by the hon. secretary (A. R. Sargeant) not only showed that the club had passed a most successful year, but that everything augured well for a continuation of its prosperity. Interest in the ordinary evening meetings, excursions, the afternoon elementary lectures, and the postal portfolio section had been sustained in a satisfactory manner, and an annual exhibition had proved a great success in every way. The treasurer's (R. C. Foskett) statement of accounts showed that the financial position of the club was extremely sound, and a balance sheet showing liabilities nil and a balance in favour of the club of £85 7s. 8d. must rejoice the hearts of all concerned. The present success and prosperity of the Hove Camera Club is due in a great measure to the personal application and ability of the indefatigable hon. secretary we are quite convinced, and the club is to be congratulated on retaining Mr. Sargeant in that rôle. J. Colman, J.P., is the president for the ensuing year, and retiring officers are re-elected. In addition to holding the 1904 exhibition, the club has readily acceded to the request of the Fine Arts Committee of the Brighton Corporation to assist them in arranging for an invitation exhibition of pictorial photographs which is intended to hold in the Brighton Corporation Art Galleries in the spring of 1905.

METHOD for Determining Formaldehyde and Trioxymethylene.—C. Kleber thus applies the reaction between aldehydes and alkali bisulphites to the determination of formaldehyde. Solution of caustic soda is added to a concentrated solution of sodium bisulphite till all odour of sulphurous acid is removed. No special precautions are necessary in this neutralisation, since a slight excess of alkali is immaterial. The solution is then diluted until 50 C.c. of it exactly neutralises 50 C.c. of N/NaOH solution. Formaldehyde acts upon this as an alkali, and it may therefore be titrated as follows:—5 C.c. of the formaldehyde solution to be tested is introduced into a flask with a little phenol-phthalein solution. As it almost always contains free acid, this is cautiously neutralised with a few drops of N/NaOH solution. The standard bisulphite solution is then gradually introduced from a burette until the red colour which first appears is discharged. With strong commercial formalin, as used in photography (of about 40 per cent. formaldehyde) the heat of combination of the aldehyde with the bisulphite is sufficient to complete the reaction; but with more dilute solutions it is necessary to warm the liquid after the first disappearance of the red colour, and add more bisulphite as it reappears, and continuing the successive additions until it no longer becomes evident on warming. 1 C.c. of the standard bisulphite solution is equivalent to 0.05 C.c. of formaldehyde. Trioxymethylene may be titrated with the same solution. 2 Gm. of the substance is gently warmed with a few drops of water; a few drops of phenol-phthalein are added, and standard bisulphite slowly run in, with constant agitation, until the solid matter is entirely dissolved and the red colour has disappeared; 1 C.c. of the standard bisulphite is equivalent to 0.05 Gm. of paraformaldehyde.—"Pharm. Rev."

The Photography and Printing Crafts Department of the Manchester School of Technology, Manchester, has just issued its summer syllabus for 1904. The subjects included are:—Natural colour photography; lecturer, Charles W. Gamble. Syllabus: Explanation of the principles underlying the synthetic and subtractive methods of colour reproduction; outline of the work of Abney, Ives, Du Haeron, Hübl, Joly, Lippmann, Lumière, and Sanger-Shepherd; the processes to be adopted for any particular class of work; colour screens and sensitive plates. Particular processes: Synthetical—The methods of Ives; the monocular and binocular Kromskops; the negative and their corresponding positives; subtractive—the Sanger-Shepherd processes for transmitted and reflected light; making the negative and positives; colour processes in conjunction with the printing press. Photo-lithography, lecturer, R. B. Fishenden. Syllabus: Fundamental principles; the action of light on bichromated col-

umen; compounds of fatty bodies with zinc, calcium, and aluminium; direct and transfer processes; indirect methods; the use of the negative and its relation to the method adopted; the various kinds of prints required; reproduction of different classes of original; lithography in colours and in combination with other processes; collotype; printing on aluminium. And Carbon Printing, by Francis Fielding. Syllabus: The principles underlying the various methods of printing, and a comparison of the processes; the printing methods in vogue; methods of sensitising, dry-plate, and carbon tissue; reversed negatives, and the methods of printing them direct in the camera and by stripping; celluloid negatives; the character of the negatives required for carbon printing; preparation of the negative; actinometers; printing on sensitive tissue; development for single transfer; the preparation of drawings and other papers to receive the printed image; the method for double transfer and the preparation of temporary supports for double transfer; transferring to final supports; the use of lantern slides, transparencies, and opals by the autotype process.

Pharmaceutical Society.—The annual dinner of the members of the Pharmaceutical Society was held last week. The President of the Society, Mr. S. R. Atkins, was in the chair, and the company, numbered upwards of 200, included Sir William Church (President of the Royal College of Physicians), Sir M. M. Bownaggee, Mr. J. Henniker Heaton, M.P., Mr. Marshall Hall, K.C., Mr. David Howard (Institute of Chemistry), Professor H. G. Shaw, Mr. W. O'Malley, M.P., Mr. J. Reid, M.P., Mr. J. W. Bownaggee (President of the Royal College of Surgeons), Dr. T. Stevenson, Mr. J. Wilson Swan, Dr. J. Attfield, Mr. T. Fairley, Mr. W. Treasurer, Mr. R. Bembridge (Secretary), Mr. T. H. Idris, Mr. T. W. Newsholme, Mr. Lough, M.P., Mr. J. W. Bowen, Mr. A. E. Ekins, and Mr. Charles Umney. The President gave the toast of "The Houses of Parliament." He said that the Society had a Bill in the House of Commons—the Pharmacy Bill—which they trusted would come to a successful issue. They had been charged by onlookers with having conceived the Bill in a sort of trade-union spirit. If they had done so, it had been no injustice, for it was one of their objects to promote the interest of their own body. He denied, however, that the Bill had been conceived in such a spirit. From the first to the last provisions it was prepared in the public interest, and all that was wanted was that the Bill should be discussed. Mr. Lough, M.P., Mr. M. Bownaggee, M.P., acknowledged the toast. The President then proposed the toast of "The Medical Profession," and said that they as pharmacists asked that in the future they should be accorded a representation, a status, in the preparation of the Pharmacopoeia, which at the present time they did not possess. Mr. William Church, replying, said that the connection between medicine and pharmacy had undergone during the last few years a remarkable change. His profession at the present time could not compare with the activity which the pharmaceutical profession showed. He mentioned a feature upon which he might congratulate his profession as theirs was that the medical profession looked with distrust on the preparations which pharmacists placed in their

Madame Curie Became a Scientist.—There is an interesting article in the St. Petersburg "Novosti" which deals with the biographical details concerning the early life of Madame Curie, the Russian lady to whom and whose husband is due the wonderful discovery of radium. The writer of the article, M. Rousakoff, was a pupil of Madame Curie's father, M. Sklodovsky, Professor of Physics at a Warsaw college. It was there where Madame Curie began her scientific career. The father's devotion to experimental science was all-pervading; theories, in his opinion, were of secondary importance, never a lesson passed in which he did not prove a theory by a practical experiment, regretting only that the resources of the laboratory did not allow for the necessities of a laboratory properly equipped. Worldly pleasures were as nothing to this impassioned scientist, and every free moment he spent among his physic bottles, being too poor to keep an assistant, M. Sklodovsky, after every experiment, had to clean his own tubes and phials. But when his daughter was old enough to do so, she gladly took this task

off her father's hands, for the child had made the laboratory her nursery, where tubes and bottles were her dolls, and where it soon became evident that she had inherited her father's passion for experimental science. Serious and thoughtful far beyond her age, the child would often pass whole days in the laboratory, enveloped in a large apron and surrounded by dusters and cloths, by means of which she put everything into perfect order. Soon she knew the place of every article, the ingredients and utensils required for every experiment, and could describe every process demonstrated before the pupils. The Professor adored his daughter, but considered her laboratory work as only play, and never seemed to dream of a serious scientific career for her. But the pupils knew better. To them, the child soon became the "professorovna" or lady-professor, and as such they gave her their allegiance and admiration. The moment came when the girl had to go to school; but this did not take her from her beloved laboratory. No sooner did she return home than she was among the tubes and retorts and phials, placing them all in their order and spending the evening in assisting her father to prepare for next day's experiments. And thus gradually the little "professorovna" became her father's unpaid assistant, working hard at the girls' school during the day, and harder still at her father's laboratory at night. The boy pupils, therefore, were not surprised when, some years after they had left the college, they heard that she had brilliantly passed the examinations at her school and had gone to Paris to devote herself entirely to the study of physics. The writer of the article, himself a Russian, ends his interesting sketch by remarking, laconically: "Perhaps if the Russian Government had been more generous towards the physical laboratories of its colleges, M. Sklodovsky might never have allowed his little girl to be initiated into the secrets of science."

Commercial & Legal Intelligence

THE Burglary at Dollond's.—At the Mansion House Police-court on Wednesday last, before Alderman Sir H. Davies, M.P., Michael Thowasso (16), Peter Carwadella (15), Angelo Gianicoli (16), Alexander Merralli (13), Charles Maroni (14), and Thomas Falney (15), all boys of Italian nationality, were charged on remand with being concerned together in breaking and entering the premises of Messrs. Dollond, 35, Ludgate Hill, and stealing a number of opera glasses and other articles. Mr. Tyson Crawford, C.C., testified to the value of the articles stolen. Sir Horatio remanded Gianicoli, Merralli, Maroni, and Falney, and sentenced Thowasso and Carwadella to one month's imprisonment with hard labour.

FRAUDULENT Uses of Photography.—The remarkable history of an enterprise known as the London Penny Omnibus Association engaged the attention of the magistrate at Westminster Police Court on Saturday, when Arthur Bartlett, forty-five, of West Ealing, was brought before Mr. Horace Smith, on remand, charged with being concerned with others not in custody in obtaining money by fraud and false pretences. Mr. Rowe, barrister, prosecuting for the Public Prosecutor, said that a man named Robert Devereux Knowles, who was wanted by the police in the beginning of 1899, started an advertisement agency in Victoria Street. Five months afterwards Bartlett joined him, and a brass plate announced the genesis of the London Penny Omnibus Association. A room was taken for 10s. a week at 637, Fulham Road, and this was called the traffic office. An old building, shared by costermongers and others, was engaged at Vanstone Place, and this was grandiloquently referred to as the granaries and stores of the association. Advertisements were then inserted in the newspapers inviting depositors to participate in a safe investment, promising 10 per cent. interest and bonuses. Among other impostures resorted to was a book of manipulated photographs taken about Christmas, 1900. As the decrepit horses owned by the association were not sufficiently numerous to fill the stalls of the stables at Walham Green they were shifted four times to make "nice pictures" of fully-occupied partitions. There was another "nice picture" of a smart coach and four, but these were borrowed for the occasion from jobmasters.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION'S MEETING.

To the Editors.

Gentlemen,—In the account of the above a suggestion was brought forward with reference to a branch for assistants. As an assistant who has served a genuine apprenticeship and who is now in his fifth year, permit me to state that I consider such a branch is not only desirable, but is gradually becoming a necessity. There are now so many young persons who, having obtained a slight knowledge of photographic technique as amateurs, come and push themselves into the ranks as professional assistants. The result is that our labour market is overstocked, and good assistants, who have given years to the study of their business, are pushed out, because duffers will work for nothing. To this latter fact the advertisement columns of the B.J.P. bear witness. It appears to me, therefore, that a branch of the P.P.A. should be formed to enable the assistants of to-day to combine, not as malcontents, to be always striking for more pay or less work, but to protect themselves from this invasion, and from those low-class photographers whose one policy is to grab and think nothing about the quality of their work or the treatment of their assistants. It would appear that the P.P.A. is waiting for a mandate from the ranks of assistants. That being the case, I believe it is the duty of the assistants to rise to the occasion. I trust that you may see fit to publish this letter as it stands, but suppressing the address. Thanking you in anticipation,—I remain, yours truly,

CARL E. PETERSEN.

To the Editors.

Gentlemen,—I notice in your report of the P.P.A. meeting last week a suggestion by Mr. Fry to promote some branch or association in which assistants could join. Although we are grateful for his kindness in bringing the matter forward, still, I should think it would be much better had we some organisation of our own. A general trades' union, that would include assistants in every branch of the profession, not forgetting the dry plate and paper coaters. The increased demand for cheap labour, combined with the large number of amateurs who help to fill these vacancies for a mere pittance in order to gain some experience, is, in my opinion, mainly responsible for the bad state and general ruination of our trade. How are we to remedy this? Immediate action is necessary, in order to discuss best means of improving matters.—Yours faithfully,

A PROFESSIONAL ASSISTANT.

May 23, 1904.

A LESSON FOR PHOTOGRAPHERS.

To the Editors.

Gentlemen,—For many years now I have made a point of purchasing one of the illustrated guides to the Royal Academy, and enjoying a feast of the good things therein displayed. Situated far from the centres of art, I can yet, through these half-tones, enjoy the pictures that I cannot see in reality. The colour is absent, true; and yet, mayhap, they are on that account more valuable to the photographer, who sees the lines and masses of the pictures, unembarrassed by the wealth of colour of the originals. In the half-tones we have monotone representations of the pictures, and from these we may learn much.

A study of the book—it is "Black and White's" guide I have—shows much that might be possible by photographic means. A careful study of these will teach the seeker after the beautiful many valuable lessons.

In the figure studies and portraiture, we are struck by the prevailing note of simplicity present in all these; accessories to the figure

or figures there are, but these do not obtrude, like the accessories of too many of our photographers; no, they are relegated to a place, and only play their part in the composition of the picture, the figure being, as it ought to be, *the* picture.

In the landscapes we find that, although true art conceals yet these all follow the accepted rules of composition; the masses and masses arrange themselves in academic methods, although elaborations of the main theme may be wide as the poles asunder. Where figures are introduced, these play their part in the scheme of composition; we instinctively feel that we would not have them absent; they are indispensable notes in the harmonic chord for the pictorial anthem. Examples might be cited, and I might mention various illustrations for special study, but what need? Everyone ought to search these out for himself—or herself—study them thoroughly, and find the why and the wherefore of the various lines and masses. The knowledge thus gained will bear fruit in the improvement of our own work.

COUNTRYMAN.

PSYCHIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—I have noticed with some interest articles appearing in some of your late numbers relating to psychic photography, well as the more exact and scientific notices of the manifestation of the "N" rays and the radiations corresponding to these rays. Persons, resembling somewhat the halos accredited to certain personalities, according to some legendary or historical accounts, desire to give some experiences. Many years ago, as a young man, I took some interest and made some investigations in so-called "psychic" phenomena, especially as connected with so-called "spirit" photography. I think I am safe in saying that pretty much of that sort of work that was exploited was "faked." None of the exploiters, beginning with Mumler, who flourished in Boston twenty-five years ago, to his numerous followers and imitators, came under my notice, would submit their work to any reasonable test that would preclude fraud or faking; consequently the results shown have no value whatever to one of unbiassed judgment.

But further than this, not very long ago, in response to a statement made in your columns alluding to a gentleman in this country who had obtained and was obtaining remarkable results relating to "spirit photography," I made the acquaintance of a party for the purpose of investigating. The results he exhibited were so evidently produced in the ordinary way, some of them being copies of half-tone prints, exhibiting the screen work prominent, that but one conclusion was obvious, that either he was imposed upon by others (as he claimed to produce them through other mediums, times), or was an impostor himself.

There is, however, one peculiar species of phenomena that I caused to notice, on account of engaging in experiments for investigating the truth of the so-called psychic photography, to which I desire to call the attention of experimenters in that line, and dropped the whole matter some twenty-five years ago. The serious every-day business problems prevented me from continuing interest in a subject that ought to be probed thoroughly by careful investigators, to which my attention was called lately by reason of the "N" ray and "personal radiations" theory advanced.

It was at the time that wet plates were exclusively used for portraiture that I repeatedly noticed, in making groups against dark plain backgrounds, that lines of light, misnamed halations, would appear behind the back, or rather shoulders and neck, of some persons wearing dark or black clothing. I attributed the phenomena, which occurred most frequently in the case of rather short-timed or under-timed plates, to the precipitation of silver upon the line of black clothing cut rather suddenly into the somewhat lighter background. But I also noticed that only one, or perhaps two, figures would show this peculiarity, and it occurred to me one day to test the matter by changing the positions of the figures in a repetition of the negative. To my surprise, I found that it occurred to the same figures only as in the first trial. I noticed the effect particularly in a group of spiritualists who were making experiments at my suggestion, where the phenomena occurred with one of them who was supposed to be what they termed a strong medium. If I can hunt up any of these negatives of twenty-five years ago, I will take pleasure in sending you prints of them.

but that time other experiments (in the photo-engraving line particular) so absorbed my leisure time that I lost sight of the matter, and after the adoption of the dry plate, shortly after, I noticed the phenomena again. Now, this is a matter worthy investigation by those having the leisure; but it is evident that rays, to be observed, must have certain conditions for their development. First of these is either a wet collodion plate, or one absolutely free from halation. I would suggest a medium rapid double-plate, backed with an opaque paint. Next, a plain dark background, or one not totally black, and a rather short exposure. It is, of course, not to be expected that the phenomena occur in every case, as I noticed it only occasionally; but when they occur, the changing of positions in a group will be the means of making the test whether it is peculiar to the person. Of course, it is necessary that the figures be outlined against a perfectly plain background, in order not to be mistaken.

With these hints, I leave the matter to the numerous readers of the Journal who have the leisure and interest to make the experiment.—Yours respectfully,
D. BACHRACH.

25 Studios, 1331, F. Street, N.W.,
Washington, U.S.A.

To the Editors.

Gentlemen,—One evening last year, I attended a rather large meeting at the offices of Mr. W. T. Stead. There I inspected a large and varied assortment of Mr. Boursnell's productions. They exhibited as illustrations as "psychic photography," the discussion of that subject being the purpose for which the meeting was called. I had been invited to act as "Leader of the Opposition," so to speak. One or two believers, including Mr. Stead, having spoken, I called upon to give my views. I gave them, honestly and fully. They were unfavourable to the photographs, and evidently useful to most of the assembled guests. It may, perhaps, interest readers to learn the impressions made upon me by the photographs displayed.

They say, at once, that I consider mere views to be valueless in a connection. Mere arguments are without weight. On the other hand, it is futile to argue that, in certain cases, the photographer could not possibly have used trickery—could not possibly know whose spirit was required to appear—could not possibly obtain a portrait of that person, even had he known. Those negative propositions which cannot be proved. Yet that is how the "faithful" argue, crying "proof," where there is no proof. On the other hand, it is equally futile to argue that the photographs are not genuine, because the photographer might not have been able to acquire the information and facilities said to be at his reach. That is how the uncompromising sceptics argue. Again, proof is obviously unattainable. Whatever credence they give to the photographer's own word, that credence conveys no proof to anyone.

It may be asked, then, if we reject all views and arguments, what is to be discussed? To that I answer, there remains all that a sensible man need care to discuss, viz., the photographs themselves. Let them tell their own story, unaided and unobscured by preconceived considerations. If we find their evidence inconclusive, it will be time enough to seek further aid. Personally, I have ceased to look further. The photographs I inspected were

direct evidences adduced were of two kinds. Firstly, such as were palpable to all, except those who are blind because they will not see. Secondly, such as are palpable only to the photographic observer.

In the first place, then, the following palpable facts were evident to the non-technical observer. Each photograph represented a person, above one of whose shoulders appeared a fair expanse of uniformly tinted background. Upon this plain area was shown a comely-subdued portrait of some supposed "spirit." In some the spirit appeared as a kind of vignette; in others, it was surrounded by a particularly hard and stiffly-draped decoration, of something analogous to book-muslin. The woven texture was clearly discernible. This drapery was said to represent the "aura" enveloping the spirit. But it did not envelope

the spirit. Had it done so, the spirit could never have shown through it. It was arranged after the fashion of drapery around a picture or a mirror. Its outline was as hard and clear-cut as the jagged edge of a broken plate. In one instance the spirit and its "aura" were not "in register." The spirit-image overlapped the aura on one side, leaving a gap between them on the other, like a picture pushed sideways out of its frame. Lastly, one could not fail to note the fact that the spirit-portraits of those who lived before the advent of photography resembled reproductions of prints and drawings, while the images of those who have lived subsequently mostly resembled reproductions of photographs. Now, I ask any man of common sense to consider these palpable facts, and then tell me what are his conclusions.

Passing on to evidences of the technical order, the self-betrayal of the photographs becomes accentuated to the last possible degree. In no case were the shadows of the spirit deeper in tint than the background, though the high lights were often as white as those of the sitter. The half-tones were deficient, as they would be in an under-exposed image impressed over a fully-exposed neutral tint. The lights and shadows were distributed in a manner somewhat similar to those of the sitter. They showed that the spirit was not self-luminous, but was illuminated from without. The spirit-images showed that kind of depreciation so distinctive of a "copy." The grain of the original paper was frequently discernible. Superadded to this, the retouching stipple of the original photograph was often in evidence. Above all, those prints which had been left untrimmed gave a damning evidence which no ingenuity can explain away. The border-line made by the rabbet of the dark-slide was, in some cases, doubled, and in some cases trebled! Surely, there would appear to be some rational connection between the double and treble exposures, thus indicated, and the results produced.

Here, again, I am content to set aside my own conclusions, and leave your technical readers to state their own deductions from the facts as shown. Mere arguments as to the impossibility, or otherwise, of trickery being employed are of no account. Once we see that (no matter how, when, or by whom) the photographs have been "faked," it must be sheer folly to waste a moment in further investigation.—I am, Gentlemen, yours, etc.,

NEVIL MASKELYNE.

Egyptian Hall, W.,
May 21, 1904.

PHOTOGRAPHY IN PRISONS.

To the Editors.

Gentlemen, "Photography lessons for prisoners, and a wide extension of general education facilities" have, says the report of the Prison Commissioners for Scotland, been attended with very successful results," says the "Daily Mail," May 18, 1904. What are they turning the profession to? Who shall we have in the ranks? We are told that working men throw down their tools and refuse to work with a "jail-bird." Is not this a matter for the P.P.A. to investigate?—Yours faithfully,

HOWARD SHAW.

25, Thames Street, Windsor,
May 23, 1904.

ACCORDING to the "Builder," some recent radiographs made in Philadelphia by the aid of radium-bromide show that the emanations from this substance are able to penetrate cast iron without difficulty, and steel to a smaller degree. "In one of these experiments," it says, "two pieces of cast iron and a piece of steel were tested, the cast iron being laid on a strip of lead—a metal almost impermeable to radium emanations. After an exposure of thirty-eight hours the negative was developed, and it then became evident that the rays had passed through both pieces of cast iron, and were intercepted by the lead, so that a distinct image of the latter was visible beneath the fainter shadow of the cast iron. Although less permeable, the steel had clearly been penetrated by the rays. Those results are of considerable interest, and suggest the use of radium as a practical means of detecting flaws in metals which are impermeable to the X-rays."

Answers to Correspondents.

- ** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.**
- ** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**
- ** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.**
- ** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

PHOTOGRAPHS REGISTERED:—

E. H. WATERMAN, 64, Grosvenor Road, Aldershot. *Photograph of the King in Motor Car Watching the Troops.*

H. E. SUMNER, 1, Queen Street, Godalming. *Photograph of Hughes' Memorial Church and Schools, Godalming. Photograph of Group of Ministers. Photograph of Interior of Hughes' Memorial Church.*

E. SCHULZE, 62, Wilmsholme Road, Withington, Manchester. *Three Photographs of Wedding Cakes.*

E. WALTERS.—As the copyright in the picture is yours, and has been reproduced and sold without your permission, you have cause of action, that is, if the facts are as stated in your letter. We should advise you to consult your solicitor on the matter.

ADDRESS WANTED. —TYPE says: "Kindly give name and address of one or two printers' outfitters' firms where I can get type, ink, etc." In reply: Penrose and Co., Farringdon Road; Winstone and Sons, Shoe Lane; Hughes and Kimber, West Harding Street, E.C.

PLATINUM TONING. —PRINCE says: "1. I shall be obliged if you would let me have the formula for platinum toning bath for wet collodion lantern slides. 2. Also a good varnish for same, to be applied with heat." In reply: 1. Any of the baths used for paper will answer if they are used more concentrated, i.e., made up with less water. 2. Ordinary negative varnish is suitable for lantern slides if it be fairly free from colour. Mawson and Swan's hard varnish is as good as any.

RATIO OF STOPS. —SAYS: "I have a Ross 6 in. by 5 in. symmetrical lens, with loose stops, which are No. 0 to 6, the first being the largest. Will you tell me the name of this system of marking and the relation of these numbers to the 'intensity ratio' system of numbers?" In reply: The lens is evidently an old one, as that was the way stops were marked until the present system was adopted. If we mistake not, the exposure required is doubled with each succeeding smaller stop. If you write to the makers they will tell you for certain, as we are not quite sure on the point.

PHOTOGRAPHING IN A CAVE. —MAG asks: "Could you give me a hint as to how much magnesium ribbon would be wanted for exposure on a group, quarter-plate size, taken in a cave, stop f. 16? I enclose a piece of the ribbon I should use, so that you may see the width." In reply: We really can give no idea as to the quantity of ribbon required, as we do not know the area to be illuminated. As the stop to be used is so small, the exposure would have to be somewhat long, and the chance of some of the figures moving is great. We should advise you to employ a flash light instead of ribbon.

BROKEN NEGATIVE. —ARTISTIC PHOTO COMPANY say: "We have had the misfortune to have a negative broken through the post, after being retouched (see print enclosed). Can you inform us how we can print from same without showing the crack, as the lady cannot sit again on account of being ill, and wishes us to fulfil the order from same without the crack being shown if possible? We might say that the film is broken. How would vignetting very close do?" In reply: As the film is broken through, and the crack prints white, the best thing to be done is to vignette the figure. The white line can then easily be spotted out. Did this not occur to you?

PHOTOGRAPHY IN NORTH AFRICA. —J. F. M. says: "I intend to make a month's voyage along the north coast of Africa on business and would like to combine pleasure with same in a photographic way. Can you give me any hints as to conditions to plates to use and exposure, etc.? I mean for snap-shots. I have a half-plate 'Sanderson' and also magazine camera. Would take both. Should extra-rapid plates or medium be used, and should exposure differ much from here? Is any book I could read up on the subject?" In reply: The correspondent will find a good deal of useful information in Mr. P. R. Salmon's book, "A Photographic Tour in the East," published by Messrs. Strangeways, Tower Street, Cambridge Circus, London, W.C., price 2s. 6d.

COLLODIO CHLORIDE PRINTS. —R. DUNCAN says: "I use collodio chloride matt. P.O.P., and get different colours in toning from brown-grey to blue-black. 1. Would you kindly inform me all shades are of the same permanency? 2. And if, when a print is left in, say, twenty minutes, would the last quality be good? 3. Some of my prints have a bronze in places just after mounting, which disappears when (this is not the bronze caused by over-printing). Please inform me how to get rid of this. 4. Are the lasting qualities of C. C. paper as good as platinotype, and how can I be confident of the permanency of my prints?" In reply: Practically, they will be equally permanent. 2. Yes. Deeper toning will no doubt remove the bronzing, but it does not show when the prints are dry, why trouble about it? 4. Theoretically, no; though they may be made stable if carefully produced.

THE Royal Society gave a banquet on Tuesday evening at Whitehall Rooms as a welcome to, and in honour of the foreign delegates attending the congress of the International Association of Academies, the inaugural meeting of which body opened on Wednesday at Burlington House. The men of science and philosophy learning who were present had come from countries north and south and east and west, and intermingled with them at dinner were many of their English confrères in allied departments of knowledge. From this point of view the gathering was one of a uniquely distinctly interesting character, significant of that concord and brotherhood of the intellectual forces of civilised lands which constitute one of the lofty ideals of the association.

AN automatic aeroplane, containing a photographic apparatus, the invention of an Englishman, says the "Express," will shortly make its appearance at the seat of war, and may be expected to have a considerable effect on the progress of the campaign. It is sent up to a considerable height, and driven four miles away from the base at which it is held captive, and brought back after taking a complete photographic map of two miles of the country over which it has hovered. Thus an army possessing this apparatus can safely obtain a detailed plan of an enemy's position, showing every particular the disposition of guns, trenches and forces. Moreover, the aeroplane will register the exact distances of all the objects photographed. Similarly, it can be sent up from the deck of a warship to photograph, for example, an enemy's harbour and fleet, thus enabling its possessor to train his guns on the object of attack with deadly effect, or to assault a position with all the advantages of an accurate knowledge of what he is attacking.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography

The Oldest Photographic Journal in the World.
ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWO PENCE.

TERMS OF SUBSCRIPTION. Post Free (UNITED KINGDOM AND THE CHANNEL ISLES).

	s. d.	France, Belgium, United States, Canada, Australia, Africa, New Zealand, Newfoundland, Germany, Russia, Portugal, Spain, Italy, Egypt, India, China, Japan, &c.

THE BRITISH JOURNAL OF PHOTOGRAPHY" JUBILEE NUMBER (1854-1904).

celebrate the completion of the fiftieth year of the BRITISH JOURNAL OF PHOTOGRAPHY we are issuing next week (June 10) a Special Jubilee Number of the publication, which is universally recognised as the oldest and most influential of its kind in the world.

The ordinary issue of the Journal of June 10 will be more than doubled in size in the text portion, and amongst other things will include, by way of supplement, an illustrated history of THE BRITISH JOURNAL OF PHOTOGRAPHY, with portraits and Biographies of the Eminent Men of Science, Naturalists, and Photographers who have been identified with the conduct of the paper during the last fifty years.

A souvenir of a unique celebration in photographic journalism the "B.J." Jubilee Number will undoubtedly be a most enormous request, as it is not too much to say that the history of the paper during the half-century of its existence is most intimately bound up with the history of photography itself.

This Special Issue of THE BRITISH JOURNAL OF PHOTOGRAPHY many thousand extra copies will be printed, as the demand for the paper will be very largely increased. Moreover, it is intended to give the Jubilee Number a specially organised world-wide distribution, so that the greatest possible publicity will be secured for the occasion on the completion of its fiftieth year of existence.

EX CATHEDRA.

Photographing Lightning. The thunderstorms that have been experienced in different parts of the country during the past week or so have been sufficient to remind us that thunder is now "in season," and will be for some few months to come. Photographs of lightning are always interesting, and often very so to meteorologists, but the opportunities for obtaining them are, frequently, few and far between, therefore, those who are desirous of securing them should be on the alert during the summer months. To those who have not yet attempted to obtain photographs of lightning a few practical hints may, possibly, be welcome. These photographs, it may be mentioned, can only be taken successfully at night, or when the sky is perfectly dark. When a storm is expected the lens of the camera should be focussed for infinity, and the dark slides filled with plates of moderate rapidity. The camera is then arranged at a window pointing in the direction of the storm. The shutter of the dark slide should then be withdrawn, the lens uncapped, and the lightning waited for. As soon as a flash occurs the lens should be capped, the shutter closed, and another slide introduced, and the operation repeated with other plates. It is not advisable to attempt to obtain two flashes on one plate. It is advisable to use a wide angle lens, as that will include a great expanse of sky, so that the chances of obtaining the electric discharge depicted on the plate is the greater. In all cases the plates should be backed so as to get the image sharply defined by avoiding halation. Photographing lightning is always tedious and uncertain work, and if the operator secures one or two good negatives with the exposure of a dozen plates he may consider himself pretty fortunate. Still a good picture of lightning when secured is an achievement and something to be proud of.

* * *

A Caution to Tourists Abroad.

The tourist season has commenced, and photographers travelling on the Continent should be careful where they use their cameras. We are once more reminded of this on reading in the daily papers of the arrest of an ex-colonel of the Royal Artillery at Belle Isle on a charge of espionage. We are not told that photography had anything to do with the arrest, but the mere fact that the gentleman was arrested shows that the French authorities are still on the alert for supposed spies. It often happens in out-of-the-way places in France that a visitor's inquisitiveness, particularly if he is accompanied by a camera, leads a suspicious or over-energetic local official to imagine he is a spy, and he is arrested accordingly. Not a few English photographic tourists have been subjected to the indignity of arrest, and been detained for hours.

B

perhaps for a day or more, while inquiries are being made about them, and, perhaps, their plates examined or spoiled. Such has been no uncommon thing in the past and possibly will not in the future, hence our alluding to the subject just now to caution our readers as to what may happen to them in some circumstances. It is pretty generally understood that in all countries, including our own, that photographing in the neighbourhood of a fort is not allowed, even if the fort itself is not included in the picture. Cameras are always looked upon with more or less suspicion on the Franco-German frontiers, and tourists should always be careful how, and where, they use them, or they may quickly find themselves in trouble. It is not pleasant to have to spend a day out of a short holiday in durance vile. Passports are now not necessary in most of the Continental countries, but notwithstanding that the English photographic tourist will do well to be provided with one. Its cost is but nominal, it may be had without any difficulty at the Foreign Office, and when obtained is good for all time. It is also well, before starting on a tour, to get it vised here at the Consulate of the country the tourist is going to; here he will be able to ascertain what restrictions, if any, there are on the use of cameras in that country. The possession of a passport will not, of course, prevent a photographer from getting innocently into trouble, but it will often materially help him out of it by proving his identity and his innocent intent. Here is another hint. It is always well to make inquiries at the hotel where the tourist is staying if there are any restrictions with regard to the use of the camera in the place before he commences to use it.

* * *

Photography and Science.

It is a little difficult to conceive, nowadays, what science would do without photography. In almost every branch it is daily requisitioned for one purpose or another. Probably no branch of science has profited so much by photography as astronomy, for much of our present knowledge in that direction is entirely due to it. Stars that are too weak in light to be seen by the eye, even with the most powerful telescopes, are detected by photography, their magnitude determined, and their position in the universe definitely located. Last week Mr. E. W. Maunder, at Gresham College, in the first of a series of four lectures on "Recent Solar Researches," dealt with the subject of the changes and movements of sun spots. During his lecture he explained that at the Royal Observatory, Greenwich, two photographs of the sun are taken daily when it is visible, and that when the appearances are specially interesting an extra number are taken. The Greenwich photographs, he said, were supplemented by others taken in India, and also in the Mauritius, and thus, as complete as possible, a photographic record is secured. With the aid of lantern slides the lecturer described the photographic operations. The lecture throughout was illustrated with slides showing the different phases of the sun spots, so that the audience could at once realise their varying appearances. At the conversazione of the University of London last week, photography was largely in evidence as illustrating its utility in science and manufactures. For example, there were photo micrographs of sections of iron and steel which had been polished and then etched by a reagent and photographed. From the photo-micrographs of the metals the expert can determine with practical exactness, the proportion of carbon in the metal, the heat at which it was worked, and the mechanical treatment it had received, and by this means was often enabled to determine the cause of fracture. Amongst the photographs shown were a series of very fine cloud photographs, and the Royal Astronomical showed a number of transparencies of the great sun spots of 1903, with the surround-

ing flocculi. Photographs were also exhibited illustrating solar and meteorological changes. There was also a very interesting exhibit in the shape of some photo-micrographs that were taken with an unusually large camera, in which the results are sharper than they are when a smaller camera is taken and afterwards further enlarged. This, by the way, is a subject that photo-micrographers would do well to take into consideration, for when the picture is taken directly to the full size required, it follows that the result should be sharper than when the work is done in two operations with the intermission of a transparency. In each operation there must necessarily be some loss of sharpness, if only from the granularity of the plates employed. As has been said above, it is difficult to see what science would be at the present time were it not for photography.

* * *

More Sea Serpent.

It is much to be regretted that there was no photographic camera on board the French gunboat *Décidée* on a recent occasion when it happened to be in the Bay of Along, on the coast of Tonkin; or, supposing that there was a camera, that there was no one who thought of using it. For there was an opportunity of securing a picture of the real sea serpent such as does not very often occur. The commander of that vessel reports to his admiral that one day about 300 yards beyond its bows appeared on the port side a large, round, black mass, which those on board took to be a rock. Then the rock moved, and it was thought to be a gigantic turtle. But when it stretched itself to its full length in vertical undulations it was seen to be a flattened serpent thirty metres, or nearly one hundred feet long. It dived right under the gunboat, and came up on the other side so close to the vessel, that the doctor, the boatswain, and several others were able, by bending over the gunwale, to get a good view of the monster. Its head and neck were like those of a turtle, and the skin generally was dark brown, with rings or patches of yellow. It emitted "jets of vapoury water," and soon afterwards disappeared. Now, here is a most circumstantial account of the appearance of a monster which is generally supposed to be a myth. But there are so many other reports of the same nature, which have been recorded in ship logs for years past that we are bound to believe that there cannot all be visionary. It is a pretty generally accepted axiom that where there are persistent rumours with regard to an occurrence, there must be a substratum of truth underlying the statements. And the appearance of what is known as the sea serpent has been so often vouchsafed for by independent and honest observers that we must believe that there is a foundation for the reports. We must, of course, allow for exaggeration in many of the tales, notably in the case of the appearance recorded by a well-meaning Norwegian bishop more than a century ago who illustrated his account with some obviously impossible pictures of the monster. Still, we must feel that there is evidence in support of its existence is overwhelming. The question is ever to be satisfactorily settled, it must be by photography, and we believe that the time is not far distant when an opportunity will come of photographing one of these appearances. We shall then be able to say without doubt whether it is really a serpent, a school of porpoises, a flight of birds, or any of the other things by which doubters have explained away the apparitions. In these days it is quite a common thing for men and women of means and leisure to take a trip round the world. They think far less of such an undertaking than did our forefathers of a journey from London to Edinburgh. They all carry cameras with them, and will rest with these globe-trotters to set at rest the mystery which surrounds the oft-encountered sea serpent.

the meantime it would be interesting to know why the artists on board the *Décidée* did not photograph the creature, which was so close to their ship that they could serve the details of its complexion.

Photographers.

In a letter signed "Countryman," which appears in our last issue, there is a very valuable hint to photographers, especially to those who, like its author, are shut out from opportunities of visiting picture exhibitions. It is that they should study the illustrated catalogues, which now, thanks to half-tone blocks, are issued in such profusion. This recommendation is a most excellent one, for although these reproductions are only in black and white—we suppose that we shall have them in colour some day—they give a true representation of form, gradation, and composition. We all know, to our sorrow, that of late years there has been considered "good form" to sneer at Academic methods of art training. The young man who has had a few months' experience with a quarter-plate camera considers himself quite competent to get on his legs at the Royal Photographic Society, and point out the weak points in the work of Michael Angelo, Raphael, or any other painter. But the thoughtful worker knows very well that this kind of bunkum, although it may impose upon the ignorant, and be of great encouragement to other quarter-plate beginners, is not worthy of a moment's consideration. There are certain laws of harmony and composition in the making of a picture, as there are in the scoring of an overture, and if we outrage them, our work, although it may excite an ephemeral notoriety by reason of its eccentricity, will not last. Those who have made a name in the world of art have done so by hard study of the principles upon which art work is based, and photographers cannot do better than follow their lead. The painter can choose his own models, and can place them in his composition where he lists. He can light them from right or left as he likes, and if one item is too obtrusive he can tone it down or eliminate it altogether. A photographer can only play such tricks with his pictures to quite a limited degree, and he can never hope to emulate the painter in anything produced by the camera. But he can ascertain by a study of the works of painters, how the wielder of the brush would have treated a given subject. And here we have the reason why photographers should omit no opportunity of visiting picture galleries, or studying reproductions of pictures. The Academy sketches started by the late Mr. Henry Blackburn represented the first contribution to this kind of pictorial literature, but now that the half-tone method has reached such perfection we get most valuable photographic reproductions of the principal pictures which appear not only at the annual exhibition of the Academy, but at most of the other galleries. These catalogues can often be picked up at the bookstalls for a very small price, and from an educational point of view they are never out of date. We would also call attention to the issue of the "Catalogue Illustré" of the Paris Salon, which is procurable in London, and of the beautifully printed "Figaro Salon." Our country correspondence has done good service in calling attention of photographers to an opportunity for study which otherwise they might have neglected.

Political Cartoonist.

The political cartoon used to be peculiar to the pages of "Punch," but it now appears in dozens of other papers. The vast increase in this class of caricature is due, of course, to the same cause—the increase of pictorial illustrations generally, namely, the cheapening of the work of reproduction by the photo-

graphic process block. One thing, at least, we may congratulate ourselves upon, and that is the great gain in refinement which characterises these drawings, coarse in execution as some of them undoubtedly are. It was not so always, as collectors of old caricatures well know. Up to the time of Cruikshank many of these productions were not only coarse in drawing, but so coarse in another way that no respectable dealer would care to exhibit them in his shop window. Many of us must often have wondered what are the feelings of our leading politicians when they see themselves caricatured week after week, not only in the pages of the comic papers, but in the daily journals as well. At last, however, we are able to lift the veil, and are able to ascertain at least how they are regarded by the advocate of Fiscal Reform, who has, perhaps, been more often the subject of caricature than any public man living or dead. The story was told the other night at a dinner given to Mr. F. C. Gould, whose drawings are so familiar to the public, on which occasion it fell to the lot of Sir H. Campbell-Bannerman to propose "the guest of the Evening." The leader of the Opposition told how one day he was in the tea-room at the House of Commons, looking at the pages of the "Westminster Gazette," in which some caricatures of Mr. Chamberlain appeared. "Are you looking at the pictures?" said the latter. "Are they not good?" "Yes," was the answer, "they are always humorous."—"And always good-natured," added Mr. Chamberlain. And he went on to remark that he rather liked being thus portrayed, and had never found in the drawings anything to complain of. This is a high compliment to Mr. Gould's good taste; and one which, no doubt, he will be very proud of. And Sir Campbell-Bannerman was no less reticent in his admiration of the artists' work, and he pointed out that the old caricaturists of the beginning of the last century and even those who came after, were often ill-natured and grotesque in their imaginings. This was a very mild way of putting it, as those who are acquainted with the old works well know. In the print room at the British Museum we one day came across a volume of a journal which had an ephemeral existence at the beginning of the Victorian era. The late Queen's marriage seems to have been thought a fit subject for satire of a most gross kind, and many pictures were published in those pages which would not for one moment be tolerated now. One thing is very evident, and that is the desire to represent the late Prince Consort as a detested foreigner. He appears in many of these cartoons, and is invariably held up to ridicule. The artists' ignorance, or that of the editor from whom he received his instructions, is exhibited by the way in which the "foreigner" is made to express himself—in the broken English of a Frenchman, not that of a German. We may all feel glad that while photography has given artists, many of whom would otherwise never have reached the public, the means of making themselves known, both they and their publishers have now learnt better manners.

ART.—Wealthy Patron: This portrait doesn't resemble my wife a particle—not a particle. Photographer: No; it doesn't look much like her, but, my dear sir, the technique, the technique. "Indianapolis Journal."

PHOTOGRAPHIC ENTERPRISE.—At the recent great fire at Lowestoft, where 300ft. frontage of mills and warehouse were ablaze at one time, Mr. H. Jenkins, of Pier Terrace, Lowestoft, secured a series of photographs of the conflagration, and, with the assistance of the Rapid Bromide Printer of his own invention, which we recently noticed in these columns, was able to have picture postcards of the event ready for sale within an hour of the negatives being taken.

ELECTRIC LIGHT AND COPYING.

WE have received so many comments, and been asked so many questions regarding our article on "Copying by Electric Light," which appeared in these pages a couple of months ago, that it may be desirable to further amplify our instructions or hints. We have been asked whether the arc-light would not be better than the incandescent. The question contains its own reply: If facility in getting work through and shortness of exposure be a paramount necessity, there can be no doubt that it is the better; but we would wish to point out that our remarks were made not for the benefit of "trade enlargers"—who, it should be presumed, need no teaching from us for the conduct of their business—but for the larger army of professional photographers, whose need for copying is simply sporadic, as it were; who do not keep apparatus constantly in position for copying purposes, but have, rather, to set it up each time occasion arises, and would desire to do it with as little disarrangement of surroundings, and with as much despatch as possible. A flexible cord with a Y branch to hold the two globes or even a single cord for one only can be attached or removed as readily as replacing a spirit lamp, and, while providing all the illuminating outfit necessary, occupies no space. As to the time of exposure, ten seconds with two 32 candle power lamps is quite sufficient when copying to the same scale. It is when an enlargement of several diameters is needed where the short exposure with an arc-light would be felt to be so advantageous. One other advantage of the latter is the greater ease with which even illumination may be obtained. It is in this matter of even illumination that any material difficulty might arise with an incandescent light. When the latter is fixed for illuminating the picture to be copied, it will generally be noticed that streaks and lines of light make their appearance in the illuminated area, brought about by the globe being of irregular thickness. There will, however, be found certain positions that it can be placed in to produce an even field of light, and this, whatever the pattern or shape of filament adopted. These positions are mainly found by placing the globe in an almost horizontal position, and revolving it till the required evenness presents itself. This irregularity of the light-area is more readily perceived if the light be first allowed to fall on an even surface, such, for example, as a piece of white cardboard; when the photograph itself is lighted up the want of evenness might not be at the outset observed but for this warning note, though it would be quickly enough noted on the negative obtained. If difficulty should be experienced it can, however, be quickly got rid of by adopting ground glass or opal globes, which give a very even glow of light. But they cause considerable increase in the time of exposure required, and, further, they cannot be so satisfactorily used with a reflector to increase the light. We recently saw a very ingenious example of a costless kind, yet very efficient. It consisted of platinotype tin cut open with a pair of shears after removing the bottom and throwing away the lid. The curved sheet of brilliantly-surfaced tin-plate thus obtained was opened out to a shallow curve to an extent found by experiment, and mounted on a rough wood base. The exact curve to be given to the tin-plate sheet was, as we say, found experimentally; but obviously the shape required was a parabola, which would reflect parallel rays from any luminous source placed at its focus. For the particular purpose we are now discussing, the use of such a reflector would serve the additional purpose of screening the lens from the light of the lamp during the exposure of the plate. This is a very important matter, for, seeing that the lamp would be placed between the lens and the object, a powerful light would be cast upon the lens which

would inevitably cause a fogged negative to be obtained unless a screen of some sort were interposed. A curious experience we ourselves met with in this connection may be noted with advantage. We had obtained an excellent 12 x 10 negative; but it was marred by a fogged margin of about an inch in width, as though the plate had been "light-struck." The box from which the plate had been taken having been laid aside for a long time we concluded that an unrecorded accidental partial exposure to light had taken place, and we used an entirely fresh box. To our surprise the same fogged margin again occurred, and we could not at once diagnose the cause. Eventually it was found that the screen we had made use of to shield the lens from the entry of extraneous light—a piece of white cardboard—was within the area of reflection (referred to in our previous article as the V area), and the picture before the camera had a glass in front, the brightly-illuminated cardboard was reflected in the glass and photographed as part of the picture. This leads to the consideration of still another case of injurious reflection, and with which we will conclude our article. If the picture to be copied has a glossy surface, or be copied behind glass, portions of it will, if the copying camera have a polished surface, be reflected from that surface and re-reflected to the lens, and an irregularly fogged image be given. With such a camera, therefore, the expedient should be adopted of destroying the possibility of injurious reflection, and possibly the simplest plan is to place a piece of blank paper or cardboard in front and pierced with an aperture just large enough to permit the lens's action to be unimpeded. A similar treatment must be extended to the table upon which the camera and copying board rests, or otherwise its reflection, especially with a light coloured wood, would mar the integrity of the image at the margin in juxtaposition.

COUNTER TALK.

By the AMATEUR OPTICIAN.

THE man who has a difficulty in getting in his accounts—who has not?—finds the trouble, annoyance, and anxiety intensified by the fact that in nine cases out of ten he starts in to collect his debts at a time when he is actually short of the money. A very successful and wealthy business man once gave me advice which, put briefly, came to this: "Never go out collecting your accounts when your pocket is empty," or, in other words, do not wait until it is really necessary you should have the money. I know the truth of this from painful experience, and I do not at all mind admitting the fact.

Looking through a prospectus of the Royal Photographic Society, I remark an omission to which I think the attention of the managers might be directed; this is a lower scale of subscriptions for country members. The matter may of course have been considered by the council of the R.P. Society, but the unevenness of the impost still remains. Many a country member rarely goes to London—I have not been in the city for five years from various causes. Why should the London members enjoy all the privileges of membership, privileges which are out of the reach of nearly all country members, and pay no more for them? Another point. Has not the "Fellowship" been cheapened very considerably of late years? I must confess that, knowing very well two or three men who use the initials F.R.P.S. after their names on their bill-heads and circulars, I am greatly puzzled as to their "special" qualifications: estimable men in their way, but absolute without the "special" qualifications in the sense one would naturally use the term. It is clear that nomination papers are signed with very little thought or discrimination. In the ca

of the R.P.S. this is regrettable but not criminal. Now in the dental profession, which I claim to know something about, I once met with a case which was, to say the least, extraordinary. The Act of 1878 (Dentists) allowed the title to all who were practising the profession alone, or in conjunction with pharmacy, prior to a certain date, which I think was December 31, 1878. There was also an exemption in favour of apprentices who at the time had not completed their indentures. Well, a few years ago I met frequently in the way of business a young fellow who practised and had his name on the register. Quite accidentally I became aware of his age, and then found that at the time of the passing of the Act in question the gentleman was of the tender age of ten years! It was of course no business of mine, and I did not investigate further, but it must be clear that at the age of ten years the boy was at school and not an apprentice; also, that when the nomination paper was signed wherein he claimed exemption, two responsible tradesmen signed their names to a declaration which was false, and might have subjected them to considerable unpleasantness.

A customer has just come in for a nice little order for a set of photographs of a number of shop fronts, the premises being for the most part in very busy thoroughfares, the work has had to be done at a time anterior to the morning milkman. My friend has been struck by the varied exposures required for such work, and at such different times as five, six, seven, and ten o'clock. At first the exposure given was an average two seconds; the lens, a rapid rectilinear, stopped down to F.22. This proved to be a correct estimate for the early morning exposures, but excessive for those later in the day, all being taken purposely without sunlight. I am inclined to think that the exposure in the earlier hours was a shade more than two seconds, as it is not easy to guarantee an absolute certainty with the lens-cap only. However, no plates were wasted, the over-exposed being amenable to the mercurial intensifier. I developed one of these over-exposed plates with the "Imperial" Standard developer, mixed firstly at normal strength, then diluted with water to three times the bulk. But, after all, the term "excessive" may not be the correct term to use in such a connection. Take a shop-window of up-to-date character, with plenty of mahogany and plate-glass, and full of goods, mostly small and of all colours; what is the correct exposure at this time of year? Really, I think the old rule of "exposure for the shadows" applies here, almost, if not quite, to the same extent as if the subject were an interior; and if we say that a good rule would be to expose for the darkest object in the window, we should not be far wrong. As a matter of fact, the so-called two-second 6 a.m. negative may have a little more sparkle than the two-second 10 a.m. plate, but the print from the latter is to my mind the more interesting and valuable of the two because, with a glass, objects quite in the deep recesses of the window enclosure may be clearly distinguished, while at the same time better lighted goods in the front have by reason of so-called over-exposure become toned down to their relative values. So much for the first batch of these negatives. My friend now proposes to use a shutter for those dealt with after 9 a.m. and before 12 o'clock; and it is quite easy to imagine that one may go to another extreme, using a shutter, with such subjects; for it is clear that comparative over-exposures may be made into good results, whereas under-exposures would be fatal.

Professional photographers of class—and as a class—do not advertise to any extent, but when they venture to call attention to their attainments and their productions in such ways as are open to a certain section of the professional element, it is pleasant to note how very effective their advertisement may become by the exercise of that æsthetic taste which, after all, is the possession of all artistic photographers of

the higher grade. I am led to this reflection because of the receipt by me of a very tasteful little card sent out by Mr. Pendry, of Nottingham; nothing elaborate or showy about it, the main feature being a specimen of this gentleman's work, with prices which are moderate, the subject a pretty little child. As this has been begged of me by several lady friends already, and will probably be shown to many others before the card goes the way of all cards, sooner or later, I cannot conceive of a more promising and permanent advertisement.

PSYCHIC AND SPIRITUALISTIC PHOTOGRAPHY.

[Abstract of paper read before the London and Provincial Photographic Association, May 28, 1904.]

It is due to the memory of the late J. Traill Taylor that record should be made of the gratitude that all students of the subject feel towards him for having so courageously championed spirit photography, having after most careful investigation found it a great truth. The last decade has brought so many new truths to the surface. X-rays, N-rays, and wireless telegraphy have familiarised us with the psychic idea of spirit vibrations, so that it is but fitting that spirit photography should be brought prominently before the photographic world.

Great progress has been made with spirit photography by unseen helpers, who have had to learn and experiment; and the examples shown this evening are of much higher excellence than were those which engaged the attention of Mr. Traill Taylor.

In tracing the effects of psychic photography, reference must be made to other phenomena. We are, of course, spirits now, and when the material body dies the spiritual one emerges, and enters upon a new stage of existence. Some two hundred years ago Addison expressed an opinion that all nature swarms with spirits, and that we have multitudes of silent and unseen spectators to all our actions. John Wesley has recorded that a woman he knew was a natural seer, who could see spirits night and day; and to-day we have thousands of clairvoyants who say that we are encompassed with clouds of witnesses, which I have abundant reason to know is true, as proved by a visit to a photographer who was a clairvoyant and a clairaudient (i.e., has the gifts of seeing and hearing spirit visitors), and to my amazement he produced a spirit photograph of my little niece, quite different to any portrait taken before she passed away. Upon another visit the photographer told me that an old gentleman was standing at my side, and when the plates were developed there was an excellent presentment of my grandfather, wearing a white cravat, as represented in an oil painting, and which the photographer could not have seen. Spirit photography seems to have originated in this country, for it was in 1851 that a young photographer, in business with a partner in Fleet Street, had frequent quarrels with his partner on account of the plates showing on development curious markings, patches, hands, and in some cases portions of a face; and, clean the plates as he would, the uncanny markings were persistent, till in despair he refused to take any more pictures, and devoted himself for years to other branches of the business.

Eight years later, Miss Houghton, of London, a worthy and conscientious lady, was told by her spirit guides that a time was approaching when spirits would be impressed upon the photographic plate, and that she would be one of the workers, and this was verified in "The Chronicles of Spirit Photography," published in 1882, illustrated with over fifty reproductions of photographs taken by Mr. Hudson, who, like all pioneers, had to suffer persecution by those who thought that anything beyond their range of knowledge must be fraud. Meanwhile our American cousins were not idle, for in 1861 W. H. Mumler, of New York, was startled to find that he

had photographed an invisible sitter, as did another photographer in Connecticut.

Mumler was subjected to severe tests by scientific and photographic experts, who had to acknowledge that the manifestations were genuine. Dr. Dean Clarke, telling how Mumler cut a new sheet of glass, and produced upon it a negative having a clear likeness of his mother who had been in spirit-land about nine years.

Quoting from "Miracles and Modern Spiritualism," by Dr. A. Russell Wallace, F.R.S. :—

"The test of clearly-recognisable likenesses of deceased friends has often been obtained. Mr. W. Hewitt, without previous arrangement, obtained perfect likenesses of two sons many years dead. The author also testified to obtaining a most unmistakable likeness of his mother. Mr. Thomas Slater, optician and amateur photographer, took a new camera of his own manufacture to Mr. Hudson's studio, saw everything done, and obtained a portrait with a second figure upon it, and on experimenting in his own house obtained remarkable results, the first containing two heads by the side of a portrait of his sister, one of those heads being unmistakably the portrait of the late Lord Brougham, the other of Robert Owen. One of the most extraordinary pictures obtained by Mr. Slater was a full-length portrait of his sister, in which there is no second figure, but the sister appears covered all over with a kind of transparent lace drapery, which on examination is seen to be made of shaded circles of different sizes quite unlike any material fabric I have seen or heard of."

Mr. John Beattie, of Clifton, an old photographer of twenty years' experience, made some valuable and conclusive experiments, assisted by Dr. Thomson, of Edinburgh, an amateur photographer of twenty-five years' experience.

The figures produced are, for the most part, not human, but white, shaded patches, variously formed, and in successive pictures change and develop with a more perfect or complete type. In one is a luminous rayed star of large size, with a human face faintly visible in the centre, these lights being accurately described by a clairvoyant present. Sometimes twenty consecutive exposures produced nothing unusual; hundreds have been made, and more than half complete failures; but the successes have been well worth the labour; they demonstrate that what a sensitive person sees, even when no one else sees anything, may often have an objective existence.

Mr. Andrew Glendenning is honoured in the annals of spirit photography. For over forty years he has experimented, written upon, and generally upheld the importance of this valuable evidence of an after-life, which is summarised in his volume entitled "The Veil Lifted." In 1893 he carried on a long series of experiments with Messrs. Robertson and Duguid, a well-known medium, and also with Mr. Traill Taylor, who, after numerous exhaustive tests, was fully convinced of the genuineness of the results obtained. The Rev. H. R. Hawies should also be mentioned, as he had the pluck to hold an exhibition of spirit photographs at his own church rooms.

Here are the four forms of psychic photographs:—

1. Of forms, symbols, flowers, auras, vibrations, etc., invisible to normal sight, but visible to clairvoyants, though clairvoyants vary greatly as to their power of spirit vision, some being able to cognise a far higher rate of spirit and etheric vibrations than are others.

2. Of emotions, such as anger, fear, etc., Dr. Baraduc, of Paris, having obtained a remarkable series of these, and he probably possesses the, at present, rare phase of mediumship which constitutes a psychic photographer; he can by placing sensitive plates near the various nerve centres and ganglions, receive markings and lights on the plates, which are to him an index of the state of the patient.

3. Of etherealised and materialised forms, or spirits who for

the time being talk, sing, move, look, behave like mortals, and are visible to all sitters at the seance; under exceptionally favourable circumstances, as many as forty may materialise during one evening. In all these cases, with the exception of some of those of Dr. Baraduc, the use of a camera is necessary.

4. When plates properly protected are held by the sitters in their hands, in the presence of a suitable medium, and markings, landscapes, pictures, and portraits are precipitated direct on to the plate by the spirit workers. The late Mr. C. Lacey had a curious collection of this class obtained during sittings extending over many years; and at the meetings of the Psychological Society Mr. Gambier Bolton and his friends have also obtained interesting results.

It may, therefore, be suggested that recognisable portraits of people deceased, at times differing from any taken while in the mortal, having been obtained, frequently under test conditions, and also that designs, faces, and other manifestations having been produced on plates without the aid of lens or camera, also under test conditions, places psychic photography above, or independent of, the rules and laws of ordinary photography. In the words of Mr. Traill Taylor: "Some were in focus, others not so; some were lighted from the left, the sitter was from the right." In the face of the accumulated testimony the time has arrived for those of us who have investigated the subject to turn the tables on those who keep repeating the parrot cry of "fraud," and request them to produce any similar results under the same conditions.

It is a curious fact that so far as my observations have proceeded every photographic medium seems to produce a class or species of work quite distinct from any other, the forms or subjects in each case manifesting in a slightly different manner.

Imitation psychic photographs are often talked of, but seldom seen. It is easy by double exposure, etc., to produce weird-looking effects, but it does not pay to do so. Where is the market?

As to painting on the background with some solution invisible to the eye, but visible to the sensitive plate, an artist who could limn some of the lovely faces shown in these photographs would adorn the walls of the Royal Academy, and not the backgrounds of a needy photographer; and the nonsensical suggestion is effectually disposed of when plate after plate is exposed with intervals of a few seconds only. I show to-night three portraits of the same beautiful spirit, all quite different, taken rapidly one after the other.

Sir W. Crookes describes in "Researches in Spiritualism" the elaborate means employed to photograph the beautiful spirit materialised of Miss F. Cook. The spirit walked and talked for nearly two hours. You will see on the screen another photograph of a materialised spirit taken with Miss F. Cook as medium, taken by flashlight, seven or eight people being present, the phenomenon of materialisation being one of God's greatest wonders.

At seances held under good conditions a small cloud of magnetic aura will rise from the floor, and in a few seconds assume a spiral shape, rapidly revolves and enlarges, and in a few more seconds a living, sentient being, pulsating with life, emotion, and vitality. Materialised spirits can be photographed by any one with a camera; but it is quite another matter to photograph the invisible that necessitates the presence of a special mediumship. It is important that all photographers carefully examine all negatives showing abnormal lights and markings, for which the plate manufacturers are often unjustly blamed; they are generally explained away as fog, faulty slides, pinholes, etc., but are very often embryonic stages of this phase of mediumship, and that consists of the ability to provide spirit workers with an aura, atmosphere, or emanation which enables them to so far materialise or crystallise their vibrations, that the sensitive plate can be affected,

though the form will not be visible to anyone but a clairvoyant. Clairvoyants can see and describe spirits posing, but the plate does not record them, owing probably to the photographer not supplying the requisite materials to enable the form to be built up, or a prejudiced or hostile frame of mind fatal to attaining good results. In rare cases where the latter's magnetism is too strong or inimical to spirit vibrations, an auric veil, or netting, may appear in front of the spirit. The size of mesh varies apparently to suit each individual case, and the photograph has somewhat the appearance of process work. With some mediums the unseen find it necessary to envelop themselves with an aura as a protection from the disintegrating human influence, giving rise to satirical remarks from those who know no better, for it would probably surprise them to learn that even we incarnate ones are surrounded with an aura sometimes to the extent of several feet, this varying with the character and thoughts of the individual.

H. BLACKWELL.

AMERICAN NOTES AND NEWS.

LIGHTING WHITE DRAPERY. To keep it from developing so far ahead of the face that it becomes "chalky," can be accomplished, say a writer in "Wilson's," by making a frame similar in shape to the vignette board used in front of the lens to vignette off the lower part of the figure, but have just the frame of this board. It can be cut out of a board or made of wire. On this frame stretch a thickness of black veiling, which can be secured at the dry goods store. Now use this screen exactly as you use your vignette board, only raise it so the entire drapery is covered with it. The veiling does not stop out the light from the drapery, but retards it, making it register slower. Some exquisite effects can be obtained by using two or three thicknesses of veiling, each succeeding thickness being about one inch less in width, which will give the effect of gradual reduction in intensity as it goes toward the base of the picture.

FOCAL LENGTHS OF LENSES.—Too little attention is paid by the average amateur photographer to the proper focal length of the lens used by him in his work. This is especially noticeable in the many specimens of amateur portraiture exhibited both publicly and privately. "The Photographic Times Bulletin" remarks:—"This same ignorance or carelessness is also too often in evidence in professional work, the professional, however, often pleading in extenuation that his studio was too short for him to use a long focus lens. The use of lenses of insufficient focal length is to a certain extent due to the desire of the manufacturer to comply with the demand for a compact instrument, thereby sacrificing one of the most important features in order that his instrument when closed will measure one-sixteenth or one-quarter of an inch less in breadth. It is generally taught that the focal length of the lens should at least equal the base-line of the plate, though it really should be at least one and one-half times the length of the base-line for the correct rendering of the perspective. When the photographer can only afford one lens he should be certain that the above requirement is complied with."

MOUNTING GLAZED P.O.P. PRINTS.—A method for mounting gelatino-chloride prints so that they lay flat and smooth and still retain their gloss, the same as when they come from the ferrotype plate, is given in "The American Amateur Photographer." If such prints are simply mounted dry the edges curl up or they are not smooth on the mount, and if mounted wet the gloss is lost. Just before putting on the ferrotype plates treat the prints to a bath of: Water, 9 ozs.; formalin, 1 oz. The prints are left in this formalin bath for three minutes and are then washed in three changes of water and then squeezed

to the ferrotype plates in the usual manner. When dry the prints may be dipped in water and mounted in the usual way without any injury to the gloss. If any of the paste gets on the face of the print it may be removed with a damp cloth without injuring the gloss. Prints may be treated with the formalin bath as soon as they are sufficiently washed, or they may be dried and treated at any subsequent time. The one thing necessary is that the prints shall be put on the ferrotype plates as soon as they are treated with the formalin and washed. In mounting the prints they should only be moistened enough to make them lay limp.

HOW TO COPY AN OLD FADED PICTURE.—Every photographer, doubtless, has at times had old faded photographs brought to him to be copied, and in some cases they were so dim that they were almost invisible. After examining the treasured old picture they would, with a frown and shake of the head, pass it back to its owner with the reply: "Am very sorry, but it is too badly faded for me to do anything with it." "The American Professional and Amateur Photographer" suggests the following way out of the difficulty:—"Proceed in the usual manner, but, instead of making only one negative, make two. Give one full time, and undertime the other just a little. For example: If you give the full negative five seconds, give the other one, say, three seconds. Care should be taken not to move the camera between the first and second exposure, as it is necessary that both negatives be of the same size, and occupy exactly the same position on the plates. If there is any retouching to do, let it be done on the full-time negative. Now take both negatives and place them together, the face of the undertimed one to the back of the full-timed one; then bind them together so that they will make one negative, as it were, and then print in the usual way. Owing to the intensity which is produced by the combined negatives the printing will be slow, which will give good contrast, as well as preserve all of the fine detail in the original picture. The result will surprise you, and you will find that the copy you make in this way is far superior to the original picture, and will please your customer to such an extent that he or she will wear 'the smile that won't come off.' Just try it."

THE DEALER'S DUTY TO HIMSELF.—If there be a better method of stimulating business, of increasing sales, of multiplying possible customers, of preventing the loss of those already secured, and otherwise assuring oneself of a trade that is constantly improving in its value, than by the active forcing of photographic literature, I am afraid it has not yet been discovered, says the editor of "Camera Craft." The connection is so plain and the inference so palpably conclusive that no argument is required. There is a dealer in a New Jersey town who has so stimulated trade in his locality that the popularity of amateur photography in his city has called down upon the heads of the residents thereof comic skits in the New York papers. To quote from a recent sample of this kind of enviable publicity: "Travellers passing through the town at night imagine the place is suffering from fire beyond the control of the Department, but it is only the residents indulging their taste for photography through the medium of the flash." The principal dealer in that town has for years ordered a certain number of copies of every photographic magazine published. This number is well in excess of the estimated sale, so that copies are always obtainable. None of the unsold ones are returned. Each one remaining unsold at the end of the month is handed to some appreciative novice, and the result of six months' practice of this method has made that dealer an enthusiastic believer in the virtue of his methods. How different is the spirit displayed by the average dealer. He complains that the small profit and trouble and expense of returning unsold copies does not warrant him in carrying them. That he is deceiving himself, robbing himself, and curtailing his possible

profits by his short-sighted policy is evident. A moment's reasoning should convince him that his duty to himself demands a different set of tactics.

STRAIGHTFORWARD PHOTOGRAPHY.—Photography has passed through various trials. It has silenced many foolish claims. It has been damaged by men unfit to practice it. It has been used for improper and immoral purposes, and more, it has been pronounced worthless and untrue, remarks a writer in the "St. Louis and Canadian Photographer." It has now gained a position where attempts to belittle it will fail; its usefulness is acknowledged. Photographic publications at home and abroad are united in claiming its worth, and rival each other in giving information for its successful practice. Intelligent and self-respecting professionals unite with the Press in forwarding such a desirable end. Perhaps it was a mistake entertained by most of the old-time photographers that a photograph should at least be distinct; not necessarily wiry, but fairly distinct. Nowadays there is a different sentiment in this regard; according to some, a picture must be a blur or it is not artistic (?). This idea may become popular. But it will be some time before men of sense will believe in it. Some publications, both home and foreign, are embellished with indistinct, mushy illustrations that are a disgrace to the art of photography. If they are artistic, then the less we have of that kind of art the better. The fact is, they are not art or commonsense, and should be retired to oblivion. They should meet a universal condemnation. Some of them, besides being dim, are so black that the outline cannot be discerned; they look as if they came from the place spoken of by the prophet Job, "A land of darkness, as darkness itself—without any order, and where the light is as darkness." Possibly the writer is too severe on such as have different opinions, but I believe that the man who "stands up" for good photography should hit such abortions, and hit them hard.

A JOURNALISTIC PHOTOGRAPHER AT THE SEAT OF WAR IN KOREA.

WHEN the first landing of Japanese soldiers took place in Korea an Enterprising American photographer stood on the bund and made pictures of that landing by the light of a magnesium flash. He was Robert L. Dunn, photographer of "Collier's Weekly," New York. The war correspondent of the "Morning Post" (Mr. J. Gordon Smith) has sent from Tokio an intensely interesting and graphic account of Mr. Dunn's later adventures with the camera during the period of the first naval engagements between the Russian and Japanese fleets. He says:—

"Mr. Dunn had gone to Korea in anticipation of war. On the night of the 7th of February he was on the bund at Che-mul-pho. He had come from Seoul. Why, he cannot say; he credits his coming to that strange journalistic premonition which some call 'newspaper instinct.' With other correspondents he had been awaiting news from St. Petersburg or Tokio to tell him if it was to be war or peace, but the mail steamers had been stopped; the wires were silent. Without an idea of what was to occur he walked about the bund, looking at the riding lights of the foreign warships. The harbour was filled. All the Powers had representative vessels there. Looking into the night beyond the fleet, which included the 'Variag,' the 'Koriets,' and 'Sungari,' Mr. Dunn saw a number of flickering points beyond the lighthouse at the harbour mouth. This was at nine o'clock. He watched the lights, which looked like big fireflies, and something, perhaps that 'newspaper instinct,' induced him to stay, despite the bitter cold. Soon the rumble of the engines of many ships sounded near, and, with hundreds of lights—torches held by soldiers and coolies—he saw that the steamers were Japanese transports. From them flotillas of boats, each thronged with troops, came out of the night, all plainly lit by the flares their occupants held. Long strings of boats and scows towed by steam pin-naces came towards the bund.

"In the first boat were coolies, perhaps a thousand of them. They

ran about the shore on landing gathering wood, planks from the wharf and drift, and soon they built a line of great fires on the bund. Some secured barrels of oil from a go-down, and coolies ran from fire to fire throwing oil on the flames. With a roar the fires leaped, flames rose high and sparks showered like fountains. The long line of fires illuminated the darkness for some distance and reflected the water, then flooding at its highest mark. What a picture scene presented, especially to those who watched from the 'Variag,' 'Koriets,' and other ships. The transports—how many there were could not be distinguished—had come, with wonderful assurance past the Russian ships to within a hundred yards or thereabouts of the shore. From there they debarked five thousand soldiers, a clad in top-coats and hoods and heavily accoutred.

"Mr. Dunn ran for his camera and apparatus, which were lying at an hotel a few hundred yards away. A few minutes later he was in the branch office of the Nippon Yusen Kaisha seeking permission from the general commanding the expedition to use a flashlight and camera on the bund. He demonstrated how the magnesium flared and incidentally photographed the general, who then laughingly gave permission. He commandeered several clerks, who carried on office chairs and a table, which were converted into a stand at the water's edge for the camera. There were some striking pictures. The photographer forgot that it was bitter cold; that his hands were freezing. Boats were being pulled ashore, and overcoated soldiers were jumping into the icy waters, waist deep, to scramble to the great fires. With the steam rising from their drying uniforms the glow on their faces and uplifted hands, and the weird effect from the leaping fires, the groups offered great picture possibilities and Mr. Dunn made many exposures, when someone shouted, 'The Russians!' Crowds had been gathering. Che-mul-pho is a small place, and news travels fast. The excited Koreans in the throng startled by the flash of the magnesium, had cried, 'The Russians!'

"The photographer ran, fearing for the camera he now valued highly. At the hotel he unloaded the machine and secreted the films. Then, reloading it, he went from fire to fire. He 'snapped' Japanese soldiers huddling about fires, others landing little boxes of ammunition, coolies piling mats of rice, and many other things before a whistle sounded, and, hurriedly forming, the soldiers marched round a corner and were gone. Mr. Dunn would have followed, but was afraid to risk the loss of his camera. Before retiring he had secured a ticket from the commanding officer permitting him to accompany the force to Seoul at daylight. Few in Che-mul-pho slept that night, but Mr. Dunn wanted a short sleep to refresh him for the work of the morrow, and he slept until five o'clock. It had been arranged—so the officer told him—that the force would entrain at six o'clock. But he found on arrival at the station that the troops had gone in the middle of the night. They had passed through Che-mul-pho, and the ships in which they came had left before daylight.

"Mr. Dunn made his way to Seoul. The Korean capital looked warlike. The photographer felt that at last war had come. Soldiers were marching in column through the dirty streets and entering the great gates with massive towers and overhanging roofs and profuse beam-work. Korean soldiers were drawn up in line here and there, but they took no part in affairs. Crowds gathered, and Japanese school children were massed to sing war-songs. Mr. Dunn knew that at noon 5,000 soldiers would mess, and he was hurrying to get a photograph of the great tiffin. At the edge of the camp a Japanese officer stopped him, and at that time the war started. A dull boom sounded miles away, then another, and still another. The Japanese officer thrust his forefingers out excitedly, pointing towards Che-mul-pho, over twenty miles away. In all the English he could command the officer said: 'Russia-Japan-cross-hear-hear.'

"The photographer forgot the mess. The war he had come to see had started twenty miles away. He ran and leaped into a jinrikisha, shouting to the 'kurumaya,' 'Five yen if you get me to the station in ten minutes.' The coolie did not understand the language, but he comprehended the five yen note waved in his face. He called two men to help him, and the three earned the money. The movement of troops had stopped all passenger trains. There was no train. Afar off the cannonading sounded, and, thinking there might be a chance to get away from the junction at San-do, seven miles away, Mr. Dunn hired another jinrikisha. Inside a

ck he had gathered seven coolies to assist the man who dragged
Madly they hurried him through villages, over frozen rivers,
ough ice-covered paddy-fields, and over great sand plains. These
e most trying. He rode, walked, ran, then rode again, and
ly reached the station. He offered a thousand dollars for the
of an engine, but in vain. He was told by the stationmaster
t no engine could now be hired y a foreigner, for war had
ted and the Japanese were in charge. There was nothing for it
to wait for the regular train. It seemed an interminable space
ime before it came, but come it did. With his precious camera
ched tight the photographer clambered into the train, and after
de that was slow, disgustingly slow, arrived at Che-mul-pho.

Mr. Dunn ran to the water's edge. The hundreds of sampan
usually there had fled. By the persuasion of flashing yen notes the
tographer got four, and, through a choppy, rough sea, hurried to
United States gunboat 'Vicksburg,' lying at anchor in the har-
r. On the way he crossed the sizzling waters over the exploded
ck of the 'Korietz.' There was no one at the rail of the
cksburg' to welcome him or to stop him from boarding. All were
ching the Russian vessels which had been wrecked by Japanese
s from the other side of the deck.

In an instant Mr. Dunn had his camera focussed and its tripod's
ts fast in the gunboat's deck; sailors who assisted him in the
k being several dollars the richer. Through the finder he saw
'Variag,' powerful as she had been a few hours since, rolling
n every wave of the flooding tide. The battle he had heard
a far was over, and the cruiser was returning with her funnels
corated, ragged holes framing the daylight beyond in the two
ks that remained. Wreckage strewn her decks. Guns were twisted
almost completely dismantled. Coats, caps, boots, and all manner
things were flung across the deck-plates. The photographer
d see all these things through the glass, and regretted that he
not on those decks with his camera. While he photographed
e curls of smoke appeared in places, small lights flickered, then
ed into huge torches. The cruiser was on fire.

Sailors of the 'Vicksburg' watched with intense feeling. They
y from fugitive Russians that forty-two bodies were being cred-
ed in that fire, which seemed to have broken out just where the
es had been hurriedly placed by the fleeing Russians. As the
sank the flames rose; when dusk came they became bright in
rest with the coming darkness. Shortly before 6 o'clock the cruiser
ered and listed over further to starboard until she sank. Before
went down, in a neutral harbour, with sailors of all the world's
ers gazing, the flames had reached her magazine, and detonations
wed quickly on each other as the shells and munitions exploded.
all the while on the deck of the 'Vicksburg' a photographer
busy making exposure after exposure, with the officers too
ested to interfere. They, like hundreds of others on many
s, were watching the destroyed 'Variag,' for which Russia had
n the Cramps of Philadelphia over a million pounds, and each
t of flame, each detonation, and each list was timed by the naval
ryers.

See the 'Sungari'—she's aflame,' a boatswain shouted from the
side. All rushed across the deck to watch the second bonfire—
photographer with them. From the side of the burning 'Sun-
they saw a boat leaving. As she left the flames rose quickly
end to end of the steamer. The man in the boat, who was
so Mr. Dunn tells me—to have gone to a French ship, had
erately fired the 'Sungari.' Like a great torch, with clouds of
e rising high, she burned all night, and the charred hulk sank
ay rose—a day which showed only the smoke-stacks and bat-
t upper-works of two vessels and a portion of the beam of
ner above the surface.

So these wrecks the photographer went at daylight, and more
res were added to the collection he made. All of these prongs
tell why he has just received a cablegram from his paper
h reads: 'Bravo, Dunn!'

YAL Institution.—His Serene Highness Albert Prince of Monaco
on Friday evening last a discourse at the Royal Institution,
sing for his subject "Oceanography," especially that section of
science dealing with marine life at intermediate depths.
Prince had equipped a ship as a whaler chiefly to
mine the marine animals on which whales feed, and his
quest he came upon several new and rare varieties, especially
abalopoda, pictures of which were thrown on the screen. Lord
n presided.

THE DERBY CONVENTION: THE EXCURSIONS.

[From the Official Handbook.]

DERBY.

DERBY, the chief town of the county bearing the same name, lies in
the valley of the Derwent, at a distance of about six miles from the
point where that river joins the Trent. It is 127 miles from London,
59 from Manchester, 39 from Birmingham, 36 from Sheffield, 29 from
Leicester, and 16 from Nottingham. It is a county borough, and its
Council consists of 16 aldermen and 48 councillors. Its population
at the 1901 census was 105,000. Since then its area has been extended,
and the estimated population in June, 1903, was 118,707. Its staple
manufactures are iron (heavy bridge and girder work and machinery),
trimmings, and lace, and various other textiles. Silk, formerly a most
important industry, has all but departed. It is the headquarters of
the Midland Railway Company, in whose locomotive and carriage shops
are employed something like 13,000 men.

HISTORY.

Derby is an ancient town. It is extremely probable that even in
Celtic times a town stood on the site, but of this there is no direct
evidence. The Roman station of Little Chester (Castrum Parvum) is
within the borough, and is, in fact, less than a mile from the Market
Place. This camp commanded a bridge over the Derwent, the piers
of which were still in existence about a century ago, and was probably
founded about 86 A.D., and continued to fulfil its purpose till the
Romans withdrew in 410. Coins, pottery, and other signs of Roman
occupation have been found rather plentifully. In Saxon times the
town was known as Northwerthig, probably owing to its position
with regard to Repton, the ancient capital of Mercia, a pretty village
about seven miles away, famous for its school and its Saxon crypt,
and well worth a visit. The Danes called it Deoraby, from which
its present name is easily derivable. It came under Danish rule about
874, and was one of the famous burghs of the Danelagh. After changing
hands several times, the Danes were finally driven out in 948 by
Edmund. At this time it was a royal borough, and had a mint of its
own, from which coins were issued down to the reign of Stephen.
In the reign of Edward the Confessor it was recorded that there were
243 burgesses, representing a population of 1,000, and that there were
14 mills. But at the time of the publication of the Domesday Book,
these had fallen to 100 burgesses and 10 mills. We are told that half
the fighting inhabitants perished with Harold at the battle of Hastings,
which will fully account for the decrease. Charters were conferred
on the town by Henry I., Henry II., and John, and the town acquired
the right of electing its own bailiff in 1202. The first royal visit
recorded was that of Edward II., on his way to Boroughbridge, and
it afterwards entertained James I. and Charles I. During the great
civil war it was an important station of the Parliamentary army, the
most prominent local leader being Sir John Gell. Other important
historical events are the fact that the ill-fated Mary Queen of Scots
stayed here during one of her melancholy passages from one prison
to another, her resting place being Babington House, the site of which
was near to the present Grand Theatre. The Earl of Devonshire pro-
claimed "The glorious Revolution" from the front of the Town Hall
in 1688, and Prince Charles Edward Stuart touched here the southern-
most point of his "invasion," in 1745. He stayed at Exeter House in
Full Street, a fine old mansion, pulled down in 1854. The oak wains-
cot round the room in which he held the council at which it was decided
to retreat, has been preserved, and now covers the walls of the Com-
mittee Room at the Public Library and Museum, where also may be
seen other relics of the period. There was serious rioting in 1817, and
again in 1831. The former was the result of a disturbance made by
the stockingers and weavers, and their leader was beheaded for high
treason, and the latter was due to the rejection of the Reform Bill.
Another rather notable local event was the suppression of local football
in 1846 at the point of the sword. This game had been played in the
streets from the earliest times, the combatants being the two parishes
of All Saints and St. Peter's. The great day for it was Shrove Tuesday,
and it was continued till it became a menace to public safety. In 1842
the town was visited by an unexplained flood, the waters of the Mark-
eaton Brook rising suddenly and placing all the principal streets five
or six feet under water. In 1645 and again in 1647 and 1665 the town
suffered severely from the plague, and this brief account sums up nearly
all that is notable in its history. It may be added that His Majesty

King Edward paid two State visits to the town when Prince of Wales, and her late Majesty Queen Victoria came in 1891 and laid the foundation-stone of the New Royal Infirmary.

STREETS.

The main thoroughfare of Derby runs nearly due N. and S. for about a mile and a half. The southern portion of this commences near the Midland station, and is known as the London Road. Reference to the plan will show that this is continued in a more or less straight line by St. Peter's Street, Corn Market, Market Place, Iron Gate, and Queen Street, terminating at St. Alkmund's Church. On this main thoroughfare are situated four of the five ancient parish churches, four of the principal banks, and many of the chief business houses. Several important thoroughfares cross or lead into this main artery of traffic. Of these the chief is at the bottom of St. Peter's Street, and for a considerable distance this covers the course of the Markeaton Brook above referred to. On the right hand coming towards the town this forms Albert Street, at the end of which is the Corn Exchange, now used in the evenings as a Palace of Varieties. On the left is Victoria Street, in which are the Royal Hotel, the new tramway offices, and the post office. Continuous with this is the Wardwick, in which thoroughfare will be found the place of meeting, the Mechanics' Institute and Albert Hall, and next door the Public Library, Museum, and Art Gallery. This street in turn leads on to Friar Gate and the high road to Ashbourne. Other main streets are the Osmaston Road, which leaves the main artery at a point locally known as "The Spot," at the top of St. Peter's Street. Along this road are the entrances to the Arboretum, a pretty little park given to the town by Mr. Joseph Strutt in 1840; the Royal Crown Derby Porcelain Company's works, which will well repay a visit, and the principal iron works. St. James's Street in the centre of the town contains the hotel of the same name, and a large portion of the post office; the Strand, which joins it, is another covered brook course, and in this are the Town Club, the Liberal Club, and the main entrance to the Art Gallery; St. Mary's Gate, opposite all Saints' Church, contains the Assize Courts and the County Council offices; and in King Street at the north end of the town stands Derby School. The streets are well lighted in the centre of the town by electricity, and in the other parts by gas, and there is a fairly good omnibus and tramcar service.

CHURCHES AND PUBLIC BUILDINGS.

A castle once existed in the town, but no trace remains, and the last mention of its existence dates back to the thirteenth century. The name is perpetuated in Castle Fields and Castle Street. In like manner no trace is left of the six religious houses which once flourished, dedicated to St. James, St. Helen, St. Leonard, and St. Mary, or of the Dominican Friary. Their name still survive in streets where they once stood. St. Peter's Church, thrice restored, still contains the oldest surviving church work, dating from the twelfth century, and containing several traces of Norman work. In the churchyard, a building now used as the parish room, was once the Grammar School. Its foundation goes back to 1160, and it is consequently among the very oldest educational institutions. The next oldest of the ecclesiastical buildings is the little chapel of St. Mary on the Bridge, now in use as a mission room for St. Alkmund's Church. This dates back to the early fourteenth century, and the bridge at whose foot it originally stood has long been gone. Next in antiquity is the fine tower of All Saints, which dates from the sixteenth century, and is one of the finest specimens existing of the Tudor Perpendicular period. From the ground to the top of the pinnacle is 210 feet, and it stands on a base fifty feet square. The body of the church is of later date, and was built in 1725. It was probably the best that could be done at the time, but is altogether unworthy of the noble tower. In the church is a very fine wrought iron screen, by Bakewell, a good altar piece, and the Devonshire Chapel, containing the tombs of many members of the Cavendish family, among them that of the famous "Bess of Hardwick" and her soldier son. Of the old church of St. Werburgh, built in 1608, tower and chancel only remain, the latter doing duty as a vestry. Here Dr. Johnson was married, and there is a fine monument by Chantrey. A new and stately church, built in 1894, from the designs of Sir Arthur Blomfield, adjoins. St. Alkmund's Church, which enshrines the remains of Derby's patron saint, was built in 1847. Its graceful spire rises to the height of 216 feet. Near it, only separated by the width of Bridge Gate, is the beautiful Catholic Church, dedi-

cated to St. Marie, built in 1839, its designer being the elder Pugin. Of the modern churches, the finest are St. Andrew's, on the London Road, generally known as the "Railway Church," designed by Sir Gilbert Scott, and St. Luke's, in Parliament Street, which was built as a memorial to Bishop Lonsdale in 1870-1.

CHATSWORTH AND HADDON HALL.

The railway journey for the first twelve miles is the same as Thurlston's, but at Ambergate we turn off and travel on the main line to Manchester, passing up the Derwent Valley and its beautiful scenery through the Matlocks and Darley Dale to Rowsley. The drive from Rowsley is a very pretty one. From the picturesque village of Beal there are two routes to Chatsworth, the one on the left bank of the Derwent being by the private road through the park, the other over the bridge and along the high road to the model village of Edenshaw. A pretty bridge spans the Derwent, called the Waterloo Bridge, and crossing this we arrive at Chatsworth.

CHATSWORTH.

The Manor of Chatsworth was acquired by the Cavendish family in purchase about the middle of the sixteenth century. It appears in the Domesday Book as a Royal possession, being then held for the King by one William Peurel, an ancestor of those Peverils whom Sir Walter Scott made so famous. It passed successively into the hands of the Leche and Agard families, and from the latter into those of the Cavendishes. Sir William Cavendish, the second husband of "Bess of Hardwick," at her earnest desire, parted with some of his southern estates in order that he might acquire lands in Derbyshire contiguous to her estates in that county. Chief among these was Chatsworth. He pulled down the old Hall of the Leches and Agards and commenced a new building, which he did not live to see finished, but which his widow completed. In this building the unfortunate Mary, Queen of Scots, suffered imprisonment no less than five times between 1570 and 1581, her custodian being Bess's fourth husband, the Earl of Shrewsbury. The furniture of the rooms she occupied is now at Hardwick, and in the park at Chatsworth may be noticed a heavy stone building surrounded by a moat, still known as Queen Mary's Bower, and where tradition says, she went daily for fresh air and exercise. Another name associated with Chatsworth is that of Hobbes, of Malmesbury, who was tutor to the second and third earls. He spent all his time between Chatsworth and Hardwick, writing all his books there, and died at the latter place in 1679, aged ninety-two.

"Pess of Hardwick's" Chatsworth was all but pulled down by his great great grandson, the fourth Earl and first Duke of Devonshire, an eminent man who shone equally as man of letters and a politician. He was prominent among those who brought over the Prince of Orange the details of the scheme being worked out by him and his fellow conspirators at a little inn on Whittington Moor, near Chesterfield. In 1688 he began to build the present Chatsworth, the architect being one William Talman, who worked under the direction of Sir Christopher Wren. A few portions of the ancient hall were retained, among them the central hall and the long gallery. The work was finished in 1700, and the last alterations and additions were made by the sixth Duke between 1820 and 1840, under the guidance of Sir Geoffrey Wyatt. The house appears now very much as it did in 1707, and few people give it credit for being so venerable in years. The splendid gardens were laid out and improved by Sir Joseph Paxton, whose fame afterwards became worldwide in connection with the Great Exhibition of 1851 and the Crystal Palace. Within the house all is stately and magnificent. The fine Landseer among the pictures should be specially noted; the beautiful statuary and the magnificent wood carving; but the space at our disposal precludes further reference in detail.

HADDON HALL.

Chatsworth is a palace, a noble pile, but it has been said, incongruously in its situation. Whether this be true or false, no such charge could be brought by the most carping critic against Haddon. Situated on its green knoll, under the lee of a lofty hill, embosomed in beautiful timber, with its broken sky line of embattled tower and turrets, and its prattling trout stream beneath, its worn grey walls seem as much the work of nature as of art. No more perfect mediæval home is to be found in the kingdom, and surely none more picturesquely situated.

At the time of the Domesday survey, Haddon was owned by Henry de Ferrars' family; but it appears shortly afterwards to have passed to the Avenells; Avice, a daughter of which family married Richard

Vernon (tempo Richard I.), and thus it passed into that celebrated family. The earliest document referring to Haddon is an authorisation by John, permitting this Vernon to fortify his house. For over centuries Haddon remained in the hands of the Vernons, and then the famous (and possibly mythical) elopement of Dorothy Vernon, heiress of the celebrated King of the Peak, Sir George Vernon, John Manners, second son of the Earl of Rutland, it passed, near the end of the sixteenth century, to the Manners family, and later to the Dukes of Rutland.

Chaplain's room, so called, onward to the Chapel. This is at the south east corner of the building, and consists of a plain Norman nave, with the south aisle considerably modified by the subsequent chipping of the caps and round arches into their present pointed form, and a chancel with a good window of the perpendicular period. The noteworthy objects here are the Norman font, the famous "squint" in the S.W. angle of the chancel, and the large carved vestment chest. As we enter or leave the chapel, we may note the beautiful bell turret rising over the entrance.

Haddon contains fragments of all the principal architectural periods from Norman to the latest Tudor. Situated on a limestone platform, overlooking the meandering Wye, its plan probably conforms pretty much to the lines of the ancient wall of the late Norman period, portions of which still survive, embodied in the later work. Owing to the slope on which it is built, the western portion is between twenty and thirty feet lower than the eastern base, which partly obscures the beautiful sky line. We enter by the main gateway, at the N.W. corner, where late Norman details may be observed; and pass into the lower quadrangle, and thence, on the right, into the

The Norman work is about 1160, the lower west window and the north aisle about 1310, the chancel, clerestory, and south arcade about 1425, and the bell turret, and probably the entrance doorway, 1455. Crossing the courtyard, we enter the main block of buildings which separates the two quadrangles, noticing as we go the State apartments, continuing the line of the chapel on the south side, with their external flight of steps. In the passage may be observed a Roman altar, found between Haddon and Bakewell, indicating that an Imperial Cohort was stationed in the vicinity. On the right of the porch is the great hall; on the left, the kitchen and its

offices, leading immediately out of which are the dungeon-like larders. The Banqueting Hall is entered through a massive oak screen, pierced by two doorways, and ornamented by antlers. An iron bracket and ring may be observed as we enter, to which, it is said, the arm of the too abstemious drinker might be fastened, so that the quantum of liquor which failed to go down his throat might pass down his sleeve! The screen forms the front of the Minstrel's Gallery, beautifully panelled—and at the opposite end of the room is the raised dais for the lord and his family; and here also is the high table from which they fed. Connected with the Banqueting Hall is the smaller and more modern dining room, with its charming Oriel window looking out over the garden, and its beautiful panelled wainscot. Ascending the stone staircase, we come to the State apartments; the drawing room, with its old tapestry, and its beautiful stucco work; the Earl's bedchamber beyond; and still further the small ante-room, or page's bedchamber.

Returning to the landing, we ascend by a flight of solid oak steps to the Long Gallery, or ball room, the most beautiful in the whole building; about 100 feet by 18 feet, this noble room extends nearly the whole length of the south side of the upper courtyard, and is wainscotted throughout in oak of superb workmanship. A fine doorway near the upper end of the gallery leads into the ante-room, where is the door through which Dorothy Vernon is said to have eloped. Hence, we pass to the State bedroom, with its great four-poster, Queen Elizabeth's mirror, fine tapestry, etc.; and thence to the old state room, with more fine tapestry, whence we may ascend to the Eagle or Peveril Tower for its glorious view. Descending, we are conducted by Dorothy's steps to the gardens, terraced one above the other with their beautiful old-world style and their charming view of the exterior of this "Stately Home of England."

BRITISH EXHIBITS AT ST. LOUIS.

THE exhibits at St. Louis are classified into 144 groups, and of this number Britain is represented in about three-quarters. The "Times," of May 26, says: "In many of the groups it must be admitted that the representation is extremely meagre—in some cases nothing at all, or a single small exhibit by a single exhibitor—but in many others this country more than holds her own, even against rivals that have cultivated the habit of taking part in international exhibitions to a far greater extent than she has."

The first department in the official classification is devoted to Education, and here Great Britain occupies an area of 6,500ft., or, if the kindred department of Social Economy be included, of 7,310ft.

The second department of the official classification is devoted to art and here the British exhibit, occupying nearly 21,000ft., is extremely good. Although the committee which organised it exercised a somewhat severe method of selection, they can justly point to it, as Mr. Humphry Ward says in the introduction he contributes to the catalogue, as among the best, largest, and most important ever sent from our shores. "It is equal or superior to the display made at Chicago; better than that made at Paris in 1900; and not inferior, in the opinion of good judges, to the remarkable collection sent to Brussels in 1897." In the four groups of Paintings and Drawings, Engravings and Lithographs, Sculpture, and Architecture this country has no fewer than 1,322 entries, the whole being fairly representative of the state of the arts in the United Kingdom and the British Empire generally during the last decade. In addition, there are three rooms devoted to arts and crafts, in which are arranged 411 exhibits of original objects of art workmanship. The galleries in which the British Art section is housed are decorated with a frieze designed, and for the most part painted, by Mr. Walter Crane, the scheme consisting of a series of shields, connected by decorative scrolls of oak, rose, and bay foliage.

Various processes of reproduction—engraving, mezzotint, photography, etc.—form the first group of the department of the Liberal Arts—a department which is remarkably comprehensive in character. The photographic exhibits are numerous and good. Of the three sections into which they are classified, the first contains 242 examples of pictorial photographs from nature by some of the most noted British workers in this field, and the second, devoted to scientific photography, illustrates in 249 exhibits various applications of photography to the study of astronomy, the minute structure of meta-

geology, biology, etc. The third consists of 300 of Sir Benjamin Stone's history photographs, and is calculated to prove particularly attractive to Americans, containing, as it does, a pictorial record of festivals, ceremonies, and old customs surviving in England, as well as of places and events of historical interest, such as Westminster Abbey, Stratford-on-Avon, and the Coronation."

Exhibitions.

DEVONPORT EXHIBITION

ALTHOUGH this exhibition has been in existence for thirteen years and has always been more or less vigorous, its members have always been content to hold only club exhibitions, to which outside photographers have not contributed, and have not until now, although present is the eleventh exhibition, invited the contributions of general photographic public. The members have now made a new departure, and have great reason to congratulate themselves upon both the quality of the exhibition and its numerical strength. Probably both these qualities have been helped by the fact that many of the exhibitors at the recent Plymouth Photographic Society Exhibition have transferred their exhibits bodily to the present one. But, beyond that, the response of exhibitors has been excellent, some of the best of those who generally exhibit will be found represented. The club is well placed in the matter of room accommodation, its home being at the Borough Technical School, where meetings are held, and where the exhibition is splendidly shown in one of the fine rooms of that institution. No exhibition in the West has been better hung, and the simple decorative scheme, as well as the hanging, is creditable in the highest degree to Mr. Alfred Earl. Nothing has been better done in the West than this. Even after all, it had been wiser to have had a little different method in the arrangement of numbers, for this part is rather a bit of a Chinaman's puzzle, and not simple at that. To those who have to look at prints over for reporting purposes the plan adopted does not conduce to the preservation of a gentle spirit, and tends to the possibility of doing an injustice to the exhibition itself. However, as the Devonport folk will live and learn, it is possible the next exhibition will in this respect be an improvement. It may be said that, as a whole, the exhibits are characterised by a general excellence that should encourage the members of the club to push on to still greater things, for it is undeniable that, though the membership is good, the number of those who have contributed is unsatisfactorily few. The patron of the club is the Lord of the Manor, the Right Hon. Lord St. Levan, who gave a gold medal for the best work in the open classes. Dr. E. S. Saunders gave a silver medal for the best work of the members. The judges were:—Mr. Henry R. Babb, F.R.P.S., master of the Technical Schools; Mr. Chas. E. Brittan, and Mr. H. Coath, F.R.P.S., and these gentlemen, representing the art and the technical sides of photography, may be relied upon as having done their best in the duties that fell to them, and no slight task either. Including sets of lantern slides, the entries exceed two hundred and fifty in the open classes. The membership exhibition run to about a hundred and ten or so. The following are the classes:—

Class 1 (Open): Landscape, Seascape, and River Scenery.—This is a good class of nearly a hundred frames, very well arranged in relation to each other, but rendering a hunt for all the exhibits one person a necessity, as well as to discover the consecutive numbers. The silver plaque is secured by William Clayden for his "A Gleam of Light" (38), a study of shipping in a hazy atmosphere with a strong patch of light in sky and reflected in a shimmering sea; but a like distinction might well have gone to Arthur Marshall's "Garden of Sleep" (44), a quiet corner in a churchyard, where wild blossoms are luxuriant, and the scene is peaceful and calm. F. Mortimer's "In the Height of the Storm" (10) is second with a bronze plaque. This is one of his fine wave studies, but we venture to think that "A Wind Sea" (9) is a trifle the better. Another bronze plaque is secured by Dr. Grindrod's "Hauling Timber" (67), a tea subject justice, and is somewhat heavily printed. Honourable mention goes to "The Silenced Highway" (6), Harold Burkinshaw,

scene, rather cleverly rendering the half-tone in the snow. picture quite worthy of a better award. "Winter" (14), by Wright, is a fine rendering, full of good quality, of a snow-laden landscape, through which flows a stream of cold-grey water, handled in every way. "Moorland, Arran," by Samuel Bourne, landscape treated in an excellent spirit. We like A. W. Hicks's "Woodland Graces" (25), a study of beautiful trees, through which sunshine plays. G. H. Faux's "Morning Mist" (27) is a very study of mist in a woodland, but there would have been more if the foreground rendering had just a suggestion of detail. Grindrod's "Going to the Meadow" (74), a flock of sheep being seen from the spectator, has much good quality in it. William Men's "A Misty Morn" (37), a soft study of fishing-boats in a tidal pool, is artistic, but the left half of the print contains the best portion of the whole. Maxwell Warmock's "The Wood" (63) is a delightful study of woodland, in which a trunk of a silver birch plays a principal part, over all a fine flush of light. This certainly deserved recognition.

Class 2 (Open): Portraiture, Figure Studies, and Animals.—A lot of clever work, and a class of good proportions, numbering about 100. There is great variety, too, and excellent technique throughout. Arthur Marshall's "A Study" (47), a charming example of portrait of a girl bending over a flower, lit softly, with a fine gradation of tones and very excellent posing, gains the gold medal given by St. Levan for the best picture in the open section. Probably The Prie-Dieu (50) is quite equal to it in every way—a serious subject, treated reverently, even to the framing, which is unious and in complete tone with the print. F. C. Bowtell's is a silver plaque for "Among the Lambs in Spring-time" (88), a creditable bit of work, but equalled, if not excelled, by several contributions in the class; say, for instance, W. Claydon's "Island Ponies," a charming study of a Dartmoor scene, or F. W. Mayne's "Breton Fisher Girl" (14), a fisher maiden on a low-tide with a softly-receding distance. H. P. C. Harpur's "With a sweat he earns what e'er he can" (45) has won a bronze medal. It is a study of an old gardener (at five o'clock, say?), who is warm, and is wiping his brow, being supported at the same by his spade, or supporting his spade, it is not clear which, he does it. This leaning spade makes a bad line, and were away or doing work on its own account. No honourable mention occur in this class, though surely there was opportunity to do so easily enough. A. R. Hunt and Muriel Hunt show some splendid examples of cat studies, but they are mounted too many on the mount, and do each other injustice. V. T. Paul's "Lighting" (82) is a portrait study of a fisherman who is lighting his pipe. Under G. Gibson has some fine bird studies, of which, perhaps, "Razor Bill" (30) stands out prominently. Dan Dunlop's "Normandy Girl" (69) is a striking example of portraiture, softly lit, and a good model. Dr. Grindrod's fine head studies, "Head of an Old Man," "Edward Elgar," and "Arbuthnot Smith," stand out as most excellent work in every way.

Class 3 (Open): Architecture and Photographic Work not included in Classes 1, 2, and 4.—This is not a very big class, but it is good quality and subject, mostly representative of architecture and photography. The silver plaque has been secured by Perceval W. Crane with "Crypt de l'Aquilon, Mont St Michel, Normandy" (13), a very creditable example of such work, but surely equalled in every way by "Doorway, Ely" (24), George H. Faux, a fine example of detail work, softly and delicately rendered, or "Chapel, Haddon" (26), by Arthur Marshall, which is awarded a silver medal. It is a fine piece of work, in which all is clear and soft, and not overcrowded with small details. The bronze medal goes to D. W. Kyle for "Begonias" (5), most excellent work, and other examples are of about equal merit, though "Shirley Temple" (4) and "Chrysanthemums" (7) perhaps excel it. E. Seydmore has honourable mention for "Flower Study" (21), a fine study of roses. Harold Burkinshaw's "The Castle Gateway" (3), S. G. Turner's "The Monk's Entrance" (8), and "The House of Prayer" (33) and S. G. Turner's "Crypt, Worcester Cathedral" (33) are creditable examples of outdoor and indoor architectural work.

Class 4, Lantern Slides (Open), is a very good lot indeed, in which the silver plaque goes to Ellis Kelsey for a lot, mostly figure work; the plaque, Thos. Wright, fruit studies; honourable mention,

F. J. Mortimer, wave studies; and Dr. Geo. H. Rodman, for radiographs of mollusca, showing the internal structure of the shells.

The Members' Section, though not so full as the open one, is characterised by good work, and in variety. It is most creditable to the members, who up to the present have not had an opportunity to show in connection with open work in their own exhibition.

Class 1 (Members): Landscape, Seascape, and River.—This is strong in numbers, reaching to nearly seventy. The silver plaque goes to J. Trouern Trend's "Evening—Barbican" (27), a picture which residents in the locality will greatly appreciate. In the quiet, soft, still water of the pool a little coasting-trading steamer lies. She is artistically got into just the right spot, and all the rest is soft and subdued. Just a little more cloud might have helped the title. Bronze plaque to Rev. H. O. Fenton for "Those green-robed Senators of mighty woods" (12), a very finely-rendered example of woodland scenery, well selected, and with technique of the best. W. H. Mayne's "Path Through the Wood" (48), is a nice bit of woodland, with just enough of detail to make it pleasant. J. Trouern Trend is very fully represented, and among the best of them are "A Tit-bit on the Tamar" (31), "Ever and anon a shadow steals swiftly by" (36), "Mirrored in the Silver Stream" (28), "Amidst Sunshine and Shade" (35). Of Alfred Earl's work, probably the best is "Eventide" (60), a scene on a local river—the Tavy. A. J. Catford has an excellent thing in the "Timber Cart" (45), a rural scene, in which the lighting is soft and well managed.

Class 2 (Members): Portraiture, Figure Studies, and Animals.—This is a small but excellent lot. In this the only award is a silver plaque to A. J. Catford for "Toilers of the Sea" (3), a fishing-boat scene in a harbour, in which necessarily there are many details, but on the whole the subject is handled with great discrimination and carefulness. The same worker's "An Attentive Listener" (4), two fishermen engaged in a yarn, is good. Alfred Earl's "From Shadow into Sunlight" (8), an old lady ascending a stone stairway, in which light and shade is well handled.

Class 3 (Members): Architecture and work not included in Classes 1, 2, and 4.—A class of excellent merit, but of moderate dimensions. W. H. Mayne secures the silver medal given by Dr. E. S. Saunders for the best picture in the Members' Section for "Softly falls the golden ray" (15), a very charming study of a belfry and an old font, in which the lighting is very cleverly managed. In "Sunshine and Shadow" (3), by J. Trouern Trend, is a well-selected bit of the front of an old house and a stairway of stone that leads up to it—strongly lit, with, however, the effect of sunlight well rendered. Rev. H. O. Fenton's "To the Lady Chapel" (1) and "Hallowed by the feet of holy men of old" (2), and W. H. Mayne's "The Sneyd Tomb, Woolstanton" (7), "Interior, Berry Pomeroy Castle" (10) and "Norman Doorway, St. Germans" (13), comprise some skilful technique and artistic selections.

Class 4, Lantern Slides (Members), though only a few over a dozen sets are of good quality. A. J. Catford has secured the silver plaque, J. Trouern Trend a bronze plaque, and honourable mention goes to Jas. Batten and Jno. F. Coombes.

On Wednesday evening Mr. Jno. F. Coombes lectured on "Down along, the history of a Scilly week-end," which was much appreciated by the large audience which gathered to hear him.

The club may be congratulated upon the successful first open exhibition it has held. Some of the success of this may be accorded to the energetic and painstaking hon. secretary, Mr. A. J. Catford, who has put great zeal and tact into the work, and who has led up to this event with thoughtful preparedness, so that the Devonport Camera Club's first start in a public way is the best exhibition it has ever held.

INAUGURAL EXHIBITION AT THE CARTWRIGHT MEMORIAL HALL.

The exhibition of pictorial photographs forms a very interesting section of the art collections in the Cartwright Memorial Hall, Bradford. These are brought together in a room in the basement, which was, indeed, originally planned by the architect as a mere workshop, but which the Cartwright Hall Committee felt, as the building progressed, was too useful a room to be devoted merely to packing-cases and the like. It has consequently been finished off in general conformity with the rest of the building, and will be a most valuable addition to the accommodation. Considerable advances

have been made by the leading workers in pictorial photography during the last few years, and even since the last photographic exhibition in Bradford the progress has been marked. The work which was then placed on exhibition came as a surprise to the great majority of the artistic public, who had enjoyed few opportunities of making themselves acquainted with the productions of the many amateurs of artistic culture who had adopted the camera as the instrument of their expression. The work of the amateurs has not been without its effect on the productions of the professional photographer, and the public have come to insist on a vastly higher standard of artistic quality, and at the same time have learnt to be willing to pay adequately for good work. If, therefore, the present exhibition is somewhat less startling than the former, in consequence of the education of the public in the knowledge of what photography itself can do, it will not be less interesting. In actual quality of work it is certainly far ahead of any collection which has previously been seen in Yorkshire.

The Exhibition Committee were fortunate in having in their midst that enthusiastic photographer, Mr. Alexander Keighley, of Keighley, and they have been able to leave entirely to that gentleman the whole responsibility of organising the section. Mr. Keighley's intimate acquaintance and influence with the leading workers in England and abroad have stood Bradford in good stead. He happily contrived to secure the assistance and interest of Mr. Alfred Stieglitz, of New York; M. Robert Demachy, of Paris; Mr. A. Horsley Hinton and Mr. Reginald Craigie, of London; and Mr. J. Craig Annan, of Glasgow, and through the assiduous labours of those gentlemen, sectional groups of work, representative of the various schools in Great Britain, in France, and America, have been brought together. The whole exhibition includes 220 pictures, about fifty representing the American Photo-Session, of which Mr. Stieglitz is the leader, and about forty are from France. Every one of the pictures included in the exhibition is the work of an individually invited contributor, and the whole collection may honestly be said to represent the high-water mark of pictorial photography.

The place of honour in the gallery is occupied by Baron de Meyer's portrait of the King, which well catches the dignified amiability of his Majesty's expression. It is, in addition, a real work of art, which is more than can be said for some of the King's painted portraits. The exhibition of work by the English photographers of eminence is peculiarly fine. The strongest department is, perhaps, among the landscapes. Mr. Keighley himself, Mr. Horsley Hinton, and Mr. Charles Job are the principal among a considerable number of exhibitors who have used their cameras upon landscape with exquisite effect. Mr. Horsley Hinton's contributions include his well-known pictures, "Melton Meadows" and "Weeds and Rushes." Mr. Keighley sends his fine study of a French peasant in her cottage, entitled "Grace before Meat." He also contributes largely to the landscapes. His "Ploughing in Tuscany," his "Picardy Pastoral," and his "Peace" fully sustain his reputation as a worker with a fine sense of the romantic in landscape. Mr. Charles Job's work is also full of poetry and of atmosphere, his "Evening Calm" being instinct with soft sunny quality. His "On the Arun" is also a memorable work. Viscount Maitland is represented by several naturalistic pieces, though lacking distinction, and Mr. Charles Moss by some broadly treated, and in many respects excellent—though not unexceptionable—works. His "Bracken and Gorse" is, perhaps, his best, though this suffers from being printed in a colour which is far from being the best possible choice. Mr. Grindrod's "Hauling Timber" is a happy piece of photography, full of vigour and movement. Mr. Cochrane's "Quarry Team" is a somewhat similar piece of composition. Mr. Bland's "Bronte Bridge, Haworth Moor," is a piece of fine, strong work which is memorable. Mr. Charles L. Emmanuel sends some clever contributions. Mr. J. Croisdale Coultas shows how, in the hands of an artist, so sordid a view as that of the river Aire near Leeds Bridge may be made delightful. Mr. Walter Bennington has a picture of London with the dome of St. Paul's looming through the smoky atmosphere—a study which reminds one of Charlotte Brontë's enthusiastic description in "Villette" of a similar scene.

The figure studies contain much clever work. Among the most powerful is Mr. Grindrod's masterly portrait of Dr. Elgar, and Mr. F. Hollyer, Mr. R. Craigie, and Mr. J. Craig Annan send some fine portrait studies of well known men, among them the particularly

fine piece of portraiture of Mr. G. J. Frampton, A.R.A., and Mr. Hermann Vezin. Mr. David Blount comes out strongly a numerous contribution, and Mr. Cochrane sends a well lighted cleverly composed portrait of a sculptor. Mrs. Barton has a set of somewhat unequal figure studies, based obviously on a study of the works of the old French and Italian painters. The among them are certainly very fine indeed in line and tone. Mr. Page Croft is also a contributor of works of high merit. The architectural pieces are not numerous, but they include Mr. Bl. "Wirksworth Church," probably one of the finest pieces of a tectural work that the camera has ever produced, and a number. Mr. F. H. Evans's clever studies of York Minster. Mr. F. Mortimer shows some capital sea studies.

The American Section is an exceedingly interesting contribution. The honours belong especially to Mr. E. T. Steichen, who has some works in the exhibition, every one brilliant successes, and some or three masterpieces. Mrs. Kasebier is also a contributor of striking and sound work, while other contributions of remarkable power come from Mr. A. L. Coburn, Mr. J. T. Keiley, and Clarence H. White. The French collection is on the whole, perhaps less interesting, though M. Demachy and M. Puyo send some excellent works.

FORTHCOMING EXHIBITIONS.

June 12-24.—First International Salon in The Hague. Sekretar Haag, Conrad Kade 63, The Hague, Netherlands.

June-October.—Glasgow Photographic Exhibition. Secretary, Gallery and Museum, Kelvingrove, Glasgow.

July 14 to September 30.—Vienna Photographic Society. Sekretar W. Burger, Karmelitergasse 7, Vienna 11.

August 1.—Andover and District Horticultural Society. Photographic Section. Hon. Secretary, W. L. Gradidge, Jubilee House, Andover.

October 1-30.—Berlin International Photographic Exposition. Franz Goercke, Berlin W. 62, Maassen-Strasse 32, Germany.

October 19-20.—Rotherham Photographic Society. Hon. sec., B. Hemmingway, Tooker Road, Rotherham.

November, 1904.—Ilford and District Photographic Society. Hon. sec., W. N. Beal, 155, Thorold Road, Ilford.

November 3, 4, 5.—Motherwell Y.M.I. Camera Club. Hon. Sec., James Dunlop, Myrtlebank, Motherwell.

November 21-26.—Sheffield Photographic Society. Joint Secretaries, J. W. Charlesworth, J. W. Wright, 62, Vale Road, Sheffield.

November 23-26.—Hove Camera Club. Hon. Secretary, A. Sargeant, 55, The Drive, Hove.

November 24-25.—Isle of Thanet Photographic Society. Hon. Sec., G. W. Simmers, Aberdeen House, Ramsgate.

December 2-8.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 20, Clarence Square, Gosport.

December 5-17.—First American Photographic Salon at New York. Secretary, S. C. Bullenkamp, Metropolitan Camera Club, 102-10 West 101st Street, New York.

December 8, 9, 10.—Muirkirk Amateur Photographic Association. Secretary, W. Barrowman, Ayr View, Muirkirk.

December 13-20.—Southampton Camera Club. Hon. Secretary, S. Kimber, Oakdene, Highfield, Southampton.

February 21 to March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Glasgow.

June, 1905.—Northern Photographic Exhibition. Secretary, F. Issott, 62, Compton Road, Harehills. Leeds.

FORTHCOMING COMPETITIONS.

June 30.—"Photographic News" Quarterly. Money prizes, silver and bronze medals for prints. Any subject. "Photographic News," Cecil Court, Charing Cross Road, London, W.C.

June 30.—Kodak. £1,000 in cash prizes for pictures taken with Kodak films and plates, etc. Kodak, Limited, 41-43, Clerkenwell Road, London, E.C.

October 1.—Thornton-Pickard. £100 cash prizes for pictures taken

Thornton-Pickard cameras and shutters. Thornton-Pickard Manufacturing Co., Altrincham.

October 10.—Luna paper. £240 cash prizes for prints on Luna paper. Messrs. Allrege and Co., 59a, New Oxford Street, London, W.C.

October 15.—Belgian Association Lantern Slide Stereogram Committee. Secretary, M. Vanderkindere, 97, Avenue Brugmann, Brussels.

October 31.—Coxin. 68 prizes for users of Coxin. Judging twelve prizes. W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

November 1.—Barnet. Nineteen classes. Prizes valued at £500 for lantern slides and prints made with Barnet products. Elliott Brothers, Limited, Barnet, Herts.

December 15, 1905.—Ilford. £750 in prizes for negatives on Ilford. Ilford, Ltd., Ilford, E.

Patent News.

The following applications for patents were made between May 9 and May 14, 1904:—

Printing Frame.—No. 10597. "Improved photographic printing frame." John Batty.

Printing Silver Pictures.—No. 10898. "A method of toning silver pictures." (Neue Photographische Gesellschaft Actiengesellschaft, Germany.) Arthur George Bloxam.

Printing Frames.—No. 10948. "Improvements in or relating to photographic cameras and to printing frames for use with same." Frederick Joseph Seaman.

Printing Screens.—No. 10951. "Means for exposing photographic films in conjunction with flexible colour screens." Joseph Thacker Clarke.

Cutter.—No. 10965. "Improved appliance for cutting circular and oval photographic prints on paper." James Davenport.

Slide and Changing Box.—No. 11064. "Improved photographic slide and changing box." Joseph Podan Howe.

Slides.—No. 11108. "Improvement in photographic objectives." Complete specification. Franz Urban and Optische Anstalt C. P. Goerz Actiengesellschaft.

The following applications for Patents were made between May 16 and May 21, 1904:

Printing Paper.—No. 11,192. "An improved method of preparing photographic printing paper in the gum bichromate process." John Page Croft.

Apparatus.—No. 11,286. "Apparatus for use in photography." Arthur Noad.

Cameras.—No. 11,677. "Improvements in hand cameras known as box or magazine cameras." Alfred Sidney Spratt.

Printing Tray.—No. 11,699. "A convertible photographic rocking tray." Percy Shelley.

MESSRS. J. J. GRIFFIN AND SONS, LTD., of 20-26, Sardinia Street, John's-Inn-Fields, W.C., have asked us to draw the attention of readers to their new advertisement scheme, in connection with which they are distributing 500 of their Cyko Cameras at nearly half price. In addition there is a prize competition in which fifty awards are to be divided amongst the 500 lucky purchasers. Particulars, conditions, etc., will be forwarded on receipt of name and address.

PARTICULARS are to hand from Messrs. Fuerst Brothers, of 17, Tottenham Lane, E.C., relating to Pinaverdol, the new colouring material of the Cyanine series, specially adapted for sensitising slides of silver collodion, emulsion for green, and for sensitising plates for orange, yellow, and green; and to Pinachrom, the sensitiser which they claim to excel in sensitising qualities their productochrom T. Hoechst. These products are manufactured by the Farbwerke vorm. Meister Lucius and Bruening Hoechst, Germany. Messrs. Fuerst Brothers are the sole agents for the United Kingdom, and will be pleased to answer any inquiries in respect to the sensitisers and dyes.

New Apparatus, &c.

The "Royal Standard" Dry Plate. Made by Messrs. Cadett and Neall, Limited, Ashted, and sold by Kodak, Limited, Clerkenwell Road, E.C.

In the past few years the rivalry among dry plate makers has been for speed. This feature has been so absorbing to the maker, and so much advertised to the consumer, that both photographers and manufacturers have been to a large extent misled. Speed secured at the sacrifice of the many other essential qualities to a good negative is a step backward instead of forward on the part of the manufacturer, and leads to many failures and disappointments to the photographer.

The "Royal Standard" plate, which we have recently tried, appears to be an excellent production in every way. It is made in two speeds, rapid and extra rapid. The rapid we found fast enough for studio exposures in good light, and for ordinary snapshots out of doors under strong actinic light conditions, yielding negatives full of gradation and easy to develop. The extra rapid we have found not only extremely fast, but with a fineness of grain not usually accompanying high speed in the modern dry plate. The makers claim great rapidity, density, freedom from fog, and lack of grain for these plates, and our experience bears out these claims fully.

Good results can be secured from the "Royal Standard" with any good standard developer; but the pyro-soda formula specially recommended gives excellent results. This formula is simple, and well within the ability of any amateur photographer both to compound and use. For the convenience of those who do not desire to mix their own developer, the "Royal Standard Developer" can be procured ready prepared, either in powder or liquid form.

Branfill's Curves for Square Measurement. Sold by A. W. Penrose and Co., 109, Farringdon Road, London, E.C.

To the photographer who has many blocks made from his prints, or, indeed, the draughtsman who desires to know the exact superficial area in square inches of any design, etc., up to 14 x 10 inches, this piece of apparatus will prove invaluable. It is a framed graduated scale of curves, so ingeniously arranged that if any flat rectangular object is placed on it, so that one corner is against the upper left-hand corner of the frame, the number on the curve nearest to the lower right-hand corner of the object will indicate the number of square inches contained in it. We have already found this an extremely useful appliance for the measurement of square inches in process and other blocks.

"Cardium" Colours. Sold by Messrs. A. Peache and Co., Orlando Road, Clapham, London, S.W.

"Cardium" transparent colours appear to be a new departure in colouring mediums for tinting photographs. They are sold in the shape of small card ovals covered with what appears to be a layer of colour embodied in gum or gelatine. A full range of colours is supplied, capable of tinting any sort of photographs on any base. They are applied by means of a brush and water in a similar manner to ordinary moist water colours, and flow very easily on glossy surfaced prints, leaving little or no brush marks. We have tried them on various prints, and the results are decidedly satisfactory and effective. The colours are put up in sets in neat tin boxes, and are inexpensive.

ERITH and District Photographic Society.—This society held its second meeting, at Mr. Major's rooms, on Friday last. A programme was gone through which embraced a flash-light demonstration and an exhibition of cinematograph films and lantern slides. A society of this kind should enlist the support of all lovers of the photographic art residing in the district, as the assistance obtainable through this medium is of intrinsic value. It is hoped that all interested in the movement will be present at the next meeting, which takes place on Friday, June 10, at 8 p.m. The address of the Secretary is Kilgraston, Erith.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

June	Name of Society.	Subject.
6.....	South London Photo. Society...	Sale and Exchange Evening.
7.....	Neelson Photographic Society...	Ozotype. Demonstration. Mr. J. Egan off.
7.....	Rotherham Photo. Society	Architectural Photography. Mr. H. W. Bennett
8.....	North Middlesex Photo. Soc. ...	Ten Minutes' Papers by Members.
9.....	London and Prov. Photo. Assn	Open Night.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 26th.—Mr. T. K. Grant in the chair. Mr. H. Blackwell read a paper entitled "Psychic and Spirit Photography," after which fifty lantern slides were projected of alleged spirit photographs, every one of which bore evidences of being produced by certain well-known methods, that of the lecturer's niece, upon which such stress was laid, showing the pattern of carpet upon the knees of Mr. Blackwell (explained later on as quite in accordance with spirit life, where astral carpets are in general use). Silver prints exhibited in the room enabled the members to judge accurately how far the effects gained were genuine spirits or not.

A visitor asked whether photographers who are clairvoyants could themselves photograph spirits. Mr. Blackwell replied that photography does not produce spirits, they come of their own volition. A clairvoyant photographer could photograph spirits, he said, but personal magnetism was important; even a new background required magnetising.

Mr. Brown was anxious to know if any spirits were present at the time, as he had a camera ready to take their photographs. Mr. Blackwell replied he had no doubt that there were many spirits present, perhaps that of the late Mr. J. Traill Taylor, but not being clairvoyant he could not be sure. Mr. Haddon had handled a great many magnets under all conditions of light, but had never seen any luminosity emanating therefrom. Mr. Blackwell was of opinion that if Mr. Haddon tried the experiment in the presence of a clairvoyant he would see emanations.

Mr. Child Bayley said it was a great pity that amongst the whole of the photographs exhibited all were such as could so easily be made by means so well known to the expert, and none which in themselves bore evidence of being purely spiritual. He had seen photographs taken under what were termed critical conditions, and the negatives showed certain signs to him which were evidence of a celluloid transparency having been used to get the spirit, such as marks made by turn buttons in a front filling slide, whilst the outer portion of negatives showed that it had been taken in a rebated slide. Mr. Blackwell could not account for Mr. Bayley's experience, but would assure the members that the spirit photographs of his niece were genuine. She had never been photographed in the two positions shown whilst alive. If Mr. Bayley wanted to imitate these photographs he would have to photograph hosts of beautiful women unlike any he knew. Mr. Traill Taylor was satisfied with the genuineness of the conditions and results, and Mr. Bayley cautioned Mr. Blackwell that the accounts of Mr. Traill Taylor's paper, which appeared in spiritualistic papers was a gross travesty of the meeting. Mr. Blackwell, continuing his reply, said that the spirit people make their own psychic negatives; he had seen the same phenomena and could not explain the reason.

Mr. Becket emphatically denied that Mr. Traill Taylor ever admitted that he was convinced of the genuineness of spirit photographs, and asked, why did not spirits do something useful. Would any photographer care to send these specimens to a competition? Spirits are said to be of higher intelligence and have greater powers than we mortals; still the presence of one unbeliever is sufficient to spoil a seance. Mr. Blackwell said that many very valuable inventions had been suggested and plans given by spirits.

Mr. Henderson, after apologising to the lecturer for having made a mistake in his identity, gave a brief account of his endeavours during a period of thirty years to secure genuine spirit photographs, but he had always failed, counter tricks were explained that were practised, but all were explained away. Miss Florence Marryat's book contained many accounts of Mr. Henderson's spiritualist efforts recorded as

genuine. Mr. Hay Taylor had written him to say that his father was not a believer in spirit photography.

Mr. Blackwell said that it was not fair to go to seances with intention of upsetting it, that if a materialised spirit be seized the medium suffers greatly, the molecules fly back to medium, seize the spirit is wicked. Mr. Traill Taylor has no doubt been able to communicate with Mr. Henderson, but he has surrounded himself with such a wall of prejudice that the spirit cannot penetrate. He said spirit photographs the camera must be magnetised, and Henderson's failure must be because his camera was not magnetised.

Mr. Kindon asked the members and visitors to thank Mr. Blackwell by acclamation for his paper, and Mr. Blackwell expressed himself very pleased with the kind receptive manner he had been treated to. He considered it was a duty to bring these subjects prominently forward, and hoped that spirit photography would open out a new world of interest.

BURTON-ON-TRENT AND Y.M.C.A. PHOTOGRAPHIC SOCIETY.

At the first meeting of the summer session of the above society F. W. Edwards gave a very successful lecture and demonstration "Hypo." The subject of his discourse, he stated, would suggest scientific or theoretical lecture rather than a practical demonstration and he had, in fact, chosen it as illustrating the harmonious relation of the science and practice of photography, and he would endeavour by a judicious mixture of theory and practice, not only to add knowledge of his auditors by elucidating the underlying principles of the chemistry of photography, but also to apply this theoretical knowledge to the practical purposes. The lecturer went on to describe the elements of which hyposulphite of soda is built, and exhibited slides of the substances, afterwards proceeding with the manufacture of showing in a very clear manner how the various elements are chemically united. Passing on to the discussion of hypo as a fixing agent, necessary to give a preliminary explanation of the action of hypo on the sensitive emulsion on the plate, when he would show how the hypo acted on the unaltered silver and rendered the image permanent. The hypo had done its work it should be got rid of as quickly as possible and before the lecture was closed he would give some excellent practical hints for the elimination of the salt, while for those who still preferred the usual method of extracting hypo by means of water he would give particulars of delicate tests for ascertaining whether any of the hypo still remained in the film. The lecture throughout was illustrated by experiments on each point touched upon, and at the close Mr. Edwards was commended for the excellent way in which he had handled the subject and the advice and important information he had imparted to those present.

CROYDON CAMERA CLUB.

MAY 25th.—It will certainly not be the fault of one or two members in the club if the gum-bichromate process is not given a fair trial by the members generally. Quite recently Mr. Hugh Allen illustrated his method of thick coating with an excess of gum and minimum pigment, and on the above date Mr. G. M. Sellors followed with a lucid demonstration of thin coatings in conjunction with micro-printing. Both approach the subject from the standpoint of endeavouring to get as fine gradation and detail as the process is capable of with an entire absence of that aggravating air which assumes the process an infinite superiority over all others. That it is the plastic of all may be taken for granted, but, on the other hand, with experienced workers, gradation is frequently lost, and a wasp and general indecision obtained, which no mere painter would touch for a moment.

Mr. Sellors dealt with the matter in an impartial spirit, as evidenced by his opening remarks. The process, he said, was not a trial one for the lazy man, it was uncertain, and the worker would rejoice if he got one good result out of ten. There was a risk that the strain involved might eventually qualify the enthusiast for one of those establishments devoted to the alleviation of mental distress. Abuse of the process was abundant and frequent, but this was to be wondered at, having regard to the many distressing exhibitions. The advantages were capability of almost unlimited reproduction, cheapness, choice of colour, and, provided durable pig-

employed, permanency. He had read up the authorities; they contradicted each other in nearly every detail and frequently themselves. Every man would therefore have to work out his own road.

The systems in use might be broadly classified as follows:—(1) Single coating. (2) Multiple coating and printing. (3) Mr. Allen's method. (4) Mr. Foxlee's method of Mariotype by pressure. The last, I thought, had not received the attention it deserved. Personally, he preferred multiple coating, by suitably adjusting the proportion of pigment at different stages, the scale of gradation, usually limited, might be enormously lengthened, and negatives so harsh as to be unprintable by any known means could be successfully dealt with. With multiple printing there was, however, the ever present fault of registration. He had obviated this by sprinkling the paper as far as possible by a preliminary wetting and drying, and then mounting it on a suitable cardboard, provided the edges of the paper were clamped over the back of the card there was no danger of the two separating in the subsequent operations. Other methods had been suggested, such as securing adhesion to slate by rubber solution, but these were needlessly complicated. A very good ready-made board could be found in an artist's oil sketching tablet.

Amongst the many practical points raised, which space will not permit us to enter into, Mr. Sellors said he preferred the sodium to the silver salt, its greater solubility gave increased sensitiveness. He also sized his papers, and thought the expensive badger hair softener unnecessary.

SOUTHAMPTON CAMERA CLUB.

June 30.—A lecture and demonstration was given by the Hon. Secretary, Mr. S. G. Kimber, on a new printing process, called "Helion."

The lecturer described Helion as a print-out silver paper of superior texture, upon which artistic and permanent results of singular richness and beauty are easily obtainable with certainty and simplicity of working.

Unlike the other makes of printing out paper, it has no intermediate organic support such as gelatine, but the paper is saturated with an emulsion only, and when properly toned with platinum, in the lecturer's opinion, as permanent and beautiful as a cyanotype itself.

In the course of an exhaustive demonstration, Mr. Kimber advised the use of plucky negatives and printing in the shade as far as possible, and emphasised the necessity for thorough washing before fixing and after fixing. He strongly recommended the use of Coddington's and Wellcome's chloroplatinite tabloids for toning. He showed how tones varying from light brown to black could be obtained at will from one and the same bath. The demonstration was illustrated with a quantity of prints from all classes of negatives, and a number of 12 x 10 flower studies taken on Barnet new orthochromatic plates which the lecturer warmly eulogised and advised for all classes of work. These were considered highly satisfactory in tone and quality. The lecturer also advocated the use of Lustralene for imparting richness and depth to all classes of matte papers.

The souvenir in connection with the Countess of Ancaster's Fête at the Albert Hall on June 2 consisted of portraits of some of the children taking part, photographed after the style of the Old Masters, by Speaight, the well-known child photographer. Most of the pictures have been copied after some famous painting of children, the backgrounds specially painted from the originals. So unique are the portraits that the Committee of Managers of the Royal Institution of Great Britain requested the loan of them for a meeting of its members a few days back. The binding is in harmony with the contents, and has been copied from a volume of the eighteenth century. The preface is also out of the common, as it consists of extracts from speeches on the work of the N.S.P.C.C. by the King, Lord Chief Justice, Mr. Asquith, and Earl Roberts. Only a limited edition was printed, and the compilers are handing over the net profits of the publication as their contribution to the funds of the Fête.

News and Notes.

ASSISTANCE for Patentees.—Inventors, photographic or otherwise, will rejoice to know that from next January the Patent Office proposes to render them some service in return for the high fees which it exacts. Under the Act of 1902 the department actually intends to inform applicants for patents whether their inventions have been wholly or partly forestalled. In the United States this has long been recognised as the primary duty of a Patent Office. Our easy-going department has left rival inventors and patentees to settle such matters for themselves by costly lawsuits.

A MUCH Photographed Tree.—We wonder how many times the famous Cheapside tree at the corner of Wood Street has been photographed. It must be getting towards its two hundred and fiftieth year, for it was planted just after the Great Fire to mark the site of St. Peter's in Chepe, which then suffered destruction. It was the last place within the City boundary where rooks built, and they were faithful to it until the middle of the last century. It has not forgotten how to put forth buds, and is now in full leaf. The terms of the leases of the low houses at the west end of Wood Street are said to forbid the erection of another storey or the removal of the tree, in which case it must be the most expensive bit of timber in existence.

DICKENS'S Home in Danger.—The peaceful quietness of Gadshill Place, the home of Charles Dickens, will soon be a thing of the past. The long, pleasant road from Strood to Gravesend will shortly be broken up by the speculative builder, and the Chatham and District Electric Tramways Company propose to make their terminus at the spot. Fortunately, Gadshill Place itself is not at present involved in these operations. But the charm the building had for its famous owner will vanish when the rural aspect of the surroundings has disappeared. Photographers should make the most of the present opportunity to secure records of the great novelist's favourite retreat before it is too late.

WHERE Hogarth Lived.—Another old house even more famous in its way than Gadshill Place, and one which has probably received scant attention from the peripatetic photographer, is William Hogarth's riverside home, now the depository of so many of his famous prints. Situate in Hogarth Lane, Chiswick, it has the popular advantage of being reached by electric tram. In the painter's time this modest, three-storied, red-brick building, now all but lost amid closely packed dwellings, thronged by the labouring classes, was a feature in the open country, sheltered by tall elms. Up till lately it was occupied by a market gardener, and it was put up for sale as the site of more small cottages. The public owe it to the artistic taste and liberality of Colonel Shipway, of Chiswick, that this memorial has been rescued from the suburban speculator. The Colonel has purchased it, and, under the direction of Mr. Frederick W. Peel, architect, the structure has been restored in all possible details to what it was when Hogarth lived there. Additional interest is given to the place by the 135 prints of Hogarth's works which adorn the still panelled walls. The house was opened on Wednesday as a Hogarth Museum, and in celebration of the event a dinner was held there on Saturday evening last. An oblong room, quaintly wainscotted, with a low ceiling and old-world windows, was used for the occasion, and, although it was the largest room in the house, only fifteen were able to sit down within it. Sir L. Alma-Tadema, R.A., presided.

ART.—At the dinner celebrating the opening of the Hogarth Museum, the toast of "Art" was submitted by Mr. Aston Webb, R.A., President of the Royal Society of British Artists, who said that the word had been somewhat degraded of recent years. There was art furniture and art fabrics, and there were art dealers. He was afraid the distinguishing feature in each case was the absolute absence of art. There were, of course, a great many things which had no art in them. A painting might be an admirable portrait and a house might be conveniently built, and yet both lack the magic touch of art of which Browning said, "The little more, how much it is; the little less, what worlds away!" Sir L. Alma-Tadema, who replied, quoted a friend of Christina Rossetti as saying, "As the sun colours flowers, so art colours life." Art had many phases—sometimes it taught a lesson and sometimes it told a story. Hogarth was a great master in both these

directions. Hogarth told stories second to none, and he was a great moral teacher. His portraits were also second to none, and the portraits not less important than pictures which told a story. The object of a portrait painter was to scrutinise the character of his sitter. We can commend these remarks to our brethren of the camera who wish to attain success as portrait photographers.

SCOTTISH ART.—It will be recognised that there is a considerable difference between the English and the Scottish schools of painting. The Southerner, for example, thinks the subject of a picture—the literary, or story side of art—is the principal object in few. The Northerner thinks more of the way the picture is painted—the technical, the artistic side of art. "Art for Art's sake" is more accepted and more understood in Scotland, and for this reason is more catered for, than is the case with those whose clients reside in her wealthier sister in the South. Therefore, the painters of the Low Countries and of Spain—notably Frans Hals and Velasquez—have exercised the greatest influence on present-day Scottish art. In earlier times, the influence of Hobbema was nearly supreme; and Patrick Nasmyth, one of the most charming of cabinet landscape painters Scotland has produced, was a result. Cuyp, Ruysdael, and Van de Velde were likewise the artistic progenitors of "Jock" and Andrew Wilson, and combined the inspiration of Hobbema and Ruysdael. Rembrandt greatly influenced Sir Henry Raeburn, and in his manner of painting heads the great Scottish portraitist's finest achievements are most easily described as being Rembrandtesque; while the Genoese period of Van Dyck was to a considerable extent echoed in the earlier full-length portraits of the same artist, and of Watson Gordon and Graham Gilbert. In the present body of the Royal Scottish Academy Frans Hals has several followers, and Velasquez is avowedly the master on whom the President, Sir James Guthrie, has formed his splendidly masculine art.—D. CROAL THOMSON in the "Art Journal."

THE NEW TRADE MARKS BILL.—The new Trade Marks Bill, which should be carefully watched by the photographic manufacturer, among others, somewhat widens the definition of registrable trade marks. "By this means," says Mr. Fletcher Moulton, in an interesting explanatory memorandum, "many trade marks will be registrable which are excellent for the purpose of distinguishing the goods of a manufacturer, but which would be excluded under the interpretation given by the Courts to the present definition. The registrability will turn mainly on the question whether the proposed mark is, in fact, distinctive, which is the only matter of practical importance in the case of a trade mark. The limitations that at present exist are highly technical, and have led to much controversy and litigation, without any commensurate benefit to the trading world." If we are not mistaken, there is another argument in favour of the measure; it prepares the way for an international system of trade marks. A feature of the measure is that under it a trade mark may be limited in whole or in part to a particular colour or colours, a proviso which, as is pointed out in the memorandum, is of special importance in view of the difficulties often experienced in getting recognition in foreign countries of British registrations. There are useful provisions as to dealing with instances of honest, concurrent use of the same or nearly identical trade marks, and as to associated trade marks—i.e., marks owned by the same proprietor for the same goods and so closely resembling each other that they would be calculated to deceive or cause confusion if they were registered by different firms. There are also useful provisions intended, subject to certain conditions, to confirm trade marks which, although they would be valid under an existing law, might be challenged on the ground that the definition at the date of their registration was narrower. Probably the most valuable of all the changes is that to the effect that the registry shall be conclusive evidence of the right to the exclusive use of the trade mark. This, it is pointed out in the memorandum, was undoubtedly the intention of previous enactments, but the language of the Acts has proved insufficient to carry out that intention.

THE PLAIN MAN AND ART.—Mr. Frederick Wedmore delivered an address on "The Plain Man and Art" at the Borough Polytechnic in connection with the South London Loan Exhibition of Pictures. The discourse was of the nature of a lively attack on the pretensions of

untrained persons to pronounce opinions on pictures or good work, and it laid down the law that the "plain man" and the artist were in two quite different worlds. The widest gulf the lecturer, Mr. Wedmore, was the gulf that divided them. The plain man, if he liked art at all, liked it for its story. The artist, whether writer or painter, liked it for its treatment. As to pictures and the understanding of them, Mr. Wedmore had no smooth words for the plain man. Despite heart-gladdening anecdotes which had reached them from the East End as to the effect produced on the "worker" by the contemplation of Mr. Watts's allegories, Mr. Wedmore was not foolish as to suppose that because there was a picture exhibited to people who had never thought about art at all became, with suddenness of miracle, ready to receive it. Whatever might be said pleasantly and flatteringly said in a sentimental catalogue of speech of a "star turn," the understanding of any great art requires two things—a temperament and a training. Half-trained people, Mr. Thackeray had indulgently noticed, hugged to their souls the second-rate. In art of any kind the second-rate was sure of the affection of the ordinary Englishman. As for the idler—whether of slums or Piccadilly—he knew nothing of art at all; and Mr. Wedmore was to say to the millionaire that the spirit of art counted for nothing in his existence, he should flatter him even more than a minor politician was wont to flatter the poor. For the relief of the unintelligent painter Heaven had sent in abundance the universal patron. Undue diligence, the lecturer declared, had been the ruin of many painters. Keeping them closely fixed to the studio narrowed their lives and narrowed and weakened their conceptions.

LORD KELVIN ON RADIUM.—Professor Rutherford's lecture at the Royal Institution last week, wherein he propounds radium as a new source of energy that might account even for the vast age of the earth, has attracted much attention. The professor referred to the theories of Lord Kelvin on this subject, the veteran physicist has been interviewed by a representative of the "Westminster Gazette" to see if he accepted the new theory. Lord Kelvin, who was reading Professor Rutherford's new book on "Radio-Activity," proceeded to quote some suggestions which he has recently published, as follows:—"But this leaves the mystery of the untouched Curie's discovery that it (perpetually?) emits heat at a ratio of about 80 centigrade calories per gramme per hour. Emission of heat at this rate goes on for little more than a year, say, 10,000 hours (thirteen and a half months), we get as much as would raise the temperature of 800,000 grammes of water by 1 centigrade. It seems to me utterly impossible that this can be accounted for from a store of energy lost out of the gramme of radium in 10,000 hours. It seems to me, therefore, absolutely certain that if emitted heat at the rate of 80 calories per gramme per hour found by Curie at ordinary temperature, or even at the lower rate of 38 by Dewart and Curie from a specimen of radium at the temperature of liquid oxygen, can go on month after month, energy must somehow be supplied from without to give the heat which gets into the material of the calorimetric apparatus." Lord Kelvin ventures to suggest—he would not put it forward as a fact—that somehow ethereal waves might supply energy to the radium while it was giving off heat to the ponderable matter around it. "The facts about radium," said Lord Kelvin in subsequent conversation, "are so wonderful and so different from anything known, or conceived, in science ten years ago, that even wild temporary hypotheses are pardonable. The whole of these wonderful facts have followed systematically on the original discovery of radio-activity by Henry Becquerel. They are a wonderful family, these Becquerels, and the public must imagine that the discovery of astounding facts about radium resulted from any particular flash of genius. Antoine Becquerel, my great-grandfather, I remember as Director of the Physical Department of the School of Science at the Jardin des Plantes. I met an introduction to him when I went over to Paris on coming down from Cambridge in 1845. His son Edmund, his grandson Henry, Henry's son John have all done very much to clear the mystery of radio-activity. But this book of Professor Rutherford's is wonderful. It is full of indisputable and mysterious fact, and the praise accord the author cannot be too exalted."

Correspondence.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

We do not undertake responsibility for the opinions expressed by our correspondents.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION MEETING.

To the Editors.

Gentlemen,—When I first read the two letters with the above heading, I thought I must have got hold of a back number of the *B. J.*, but no, it was dated May 27, 1904. We have had these sort of letters before. It has been decided over and over again that something must be done, and that at once, but it never is. The reason is simple. The workers in any trade to do any good in the way of improving their condition must be able to control two things, viz., the working hours and the rate of wages. In photography, for various reasons, this is impossible.

It is quite true that the ranks of more-or-less incompetent assistants are filled to overflowing; and here I would offer a word of advice to boys of an apprenticeable age, who, having bought a "Brownie" and taken successful pictures of father, mother, and the baby, think they will become professional photographers. Give up the idea, my young friends, and go in for some trade or profession which supplies everything everybody wants, but do not make for themselves. It may mean all the difference to you, between a good square meal at regular intervals and genteel starvation.

If the P.P.A. would only bring its long-talked-of scheme of certificated assistants to a head, and could induce employers to engage only certificated workers, it would do more to improve the position of incompetent men in six months than all the Assistants' Unions could in a lifetime.—Yours truly,

DROP SHUTTER.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

To the Editors.

Gentlemen,—I have noticed with some interest articles appearing in your valuable paper concerning the formation of a branch connected with the P.P.A. for the benefit and interests of professional assistants. We all must admit that Mr. Fry's suggestion is a good one. It is a very easy matter for professional assistants to form a society that may prove profitable to them, but I really think it is the duty of our seniors, such as the P.P.A., as it is to-day, to form a branch for assistants. Certificates are also a necessity. As it is rather hard for a clever young artist to have no more distinction than a duffer, who is depending on the same level, through working for next to nothing, to gain experience.

I shall be glad to read in the *BRITISH JOURNAL OF PHOTOGRAPHY* that a branch is being formed.—Yours truly,

C. H. B.

May 28, 1904.

PITY THE POOR ASSISTANTS.

To the Editors.

Gentlemen,—May I ask a small space in your valuable paper, to the assistants' grievance? An operator of great experience tells me he has answered sixty advertisements, always enclosing a stamp in reply; but out of all that number he has not received one reply. I also know several cases where legal proceedings were threatened before their specimens, etc., were returned, and in some cases they are not returned at all. No doubt there are a very great many answers to all the advertisements in the *BRITISH JOURNAL OF PHOTOGRAPHY*, but I think you will agree with me that a photographer should at least return photos, references, specimens, etc. I am sorry to say this applies more to so-called first-class photographers.—I am, yours faithfully,

A POOR ASSISTANT.

THE KODAK COMPETITION.

To the Editors.

Gentlemen,—Will you be kind enough to announce in your columns that at the grand Kodak amateur competition, in which £1,000 is to

be given in cash prizes, will close on June 30. Perhaps you would be good enough to state also, since there seems to be misapprehension in the minds of some of our competitors, that under Condition 7 of the N.C. film competition, it is stipulated that not less than three prints are to be entered; this, of course, means prints from separate negatives, not three prints from one negative.—Yours faithfully,

May 28, 1904.

KODAK, LIMITED.

41-43, Clerkenwell Road, London, E.C.

PSYCHIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—Reading over the very interesting letter of Mr. N. Maskelyne on psychic photography, I find that the damning evidence given by him is not such a proof of fraud as he thinks, if he has seen only the prints, and not the negatives. Allow me to say here that I am not a believer in these psychic photos, but the border lines doubled or trebled can be obtained, and probably are a daily occurrence with many, as if you consult the prints in the printing frame, and do not replace it in the same position, especially when printing in the sunlight, these border lines will show easily. The case would be different, of course, as I said above, if the negative shows these lines.—Yours very truly,

A. LEVY.

Asnières (Seine), May 27, 1904.

To the Editors.

Gentlemen,—In view of the letter of Nevil Maskelyne in your issue of May 27, I would refer him to my letter on the above in your issue of May 6, and I ask you, in fairness to Mr. Boursnell, to allow me to supplement that letter with further information in his favour, and I have nothing to say against him. From 1895 to 1898 I went to his studio over fifty times, and obtained a larger number of spirit photos than any other of his customers—about sixty in all, under the test conditions enumerated in the said letter.

To get at the root of spirit photography, a thorough investigation must be made of the *modus operandi*, in the place itself where they are produced, as well as a careful and oft-repeated scrutiny of the man bringing them to light, as regards not only his demeanour and motive, but so as to enable one to arrive in due time at a correct appraisal of his moral character. "A tree is known by its fruit." But though the fruit of human character is very complex in some people, we can by perseverance in the study and the ripening process of dilatory time arrive by dissection at such an estimate of him as will remain permanent in our memories. Mr. Boursnell is undoubtedly a man of perfect honesty. Any person forming an opinion of his photographs without all-round inquiry, leaving no stone unturned, no chink uncovered, that will let in the light upon them, is liable to harbour a wrong conclusion. The difference between my sixty spirit photos and a "faked" photograph is just similar to that between a natural flower and an artificial one. Let N. M. place one of my photos and a "faked" photo side by side, and even he will perceive the difference, consisting largely of finer texture in everything depicted in the spiritual. In every transaction with the spirit photographer I bought the negative. I sold the entire collection recently to Mr. Blackwell, the amateur collector of psychic photos, he being, of course, a connoisseur, who, like Mr. Stead and the late Mr. Traill Taylor, can pick out a genuine spirit picture from among a number of counterfeits, or vice versa, with one eye. Much the same as dealers in gems tell the genuine from paste. When I was a youth I went to see Professor Anderson, "the Wizard of the North," an old-time conjurer, at the Amphitheatre, Liverpool. I saw through half his tricks at my first visit, and in the course of a second visit I mastered the remainder, and explained to my friends how the Wizard operated. I am sure that if Mr. Boursnell had but once used trickery under my eyes he would not have escaped detection. It is a cruel injustice to him to suggest in a publication of the high authority of the *BRITISH JOURNAL OF PHOTOGRAPHY* that his work is "faked."—Yours truly,

J. E. STERLING.

BUFF: "Have you no memento of your mother-in-law, who came to so sudden an end in Africa?" DUFF: "No, worse luck. We only succeeded in getting a photograph of the cannibal that ate her."

Answers to Correspondents.

- ** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.**
- ** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**
- ** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.**
- ** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

PHOTOGRAPHS REGISTERED :—

S. Yeo, 54, High Street, Dorking. *Photograph of the Dorking Town Military Band.*
 F. Bustin, 151, Cheltenham Road, Bristol. *Three Photographs of Johnnie Trinley.*
 T. H. Price, Parsonage street, Dursley, Glos. *Two Photographs of Three Young Pipers and Bitch.*
 J. A. Derbyshire, 10, N. W. Market Street, Chorley. *Photograph of H. Bradley, Esq.*

 T. S. Robinson, 185, High Street, Homerton, London. *Photograph of Salvation Army Band, Congress Hall, Clapton, London.*

STAINED PRINTS.—"M. A. C." asks: "Will you kindly give me the cause of stains in prints as per enclosed, as this comes after mounting? Is there insufficient washing? Paper used is P.O.P." In reply: The stains are due, in a word, to carelessness. The prints have been allowed to stick together while in the fixing bath. You say that the stains come after the prints are mounted. The two sent, which are badly stained, have not been mounted at all.

PHOTOGRAPHS OF THE MOON.—L. FINLAY asks: "Would you kindly answer the following—(1) Did Daguerre take the first photo of the moon? (2) Can flying bullets be photographed? In reply: (1) Daguerre did not, we believe, ever photograph the moon. It was photographed in 1854 or 1855 by Jas. Hartup, and at about the same time, or a little later, as a stereoscopic picture by the late Warren DeLa Rue. (2) Yes; Professor Boys produced some very successful ones some years ago.

"T. B."—Your letter and the untuned prints you send puts quite a different complexion on the matter. If you, as you say, can taste the hypo on the negatives, it is not at all surprising that the prints are stained before they are toned, except where the film of the negative is protected by the retouching medium, which acts, to an extent, as a varnish. We should advise you, as an employer, to personally see that the negatives are properly fixed and washed, and when that is done that they are varnished afterwards, whether you print out of doors or in.

OPINION WANTED.—"STIGMATIC" says: "I shall be obliged if you would kindly pass your opinion upon the lighting, posing, and retouching of enclosed prints. Would they be considered first-class work?" In reply: The work is fairly good, that is all we can say of it. It is certainly not first-class. In the worked-up print, accompanied by the untouched one, the likeness has been altered. The lighting of the so-called "Rembrandt" one is by no means good. From merely seeing three specimens, which may be picked ones or not, it is impossible to give any idea of the salary that might be commanded.

SILVER PRINTS.—E. MOORE asks: "Would you kindly give me the address of a reliable firm who supply silver prints for crystoleum printing? Is the silver process a difficult one to work? Would you kindly state how it is worked?" In reply: This is a rather curious query, inasmuch as all prints, except carbon and platinum, are silver prints. As, however, our querist mentions "crystoleum," we assume that he refers to prints on albumenized paper. These most professional photographers will supply. If he wishes to produce them himself, we should advise him to purchase a cheap elementary manual on photography.

COPYING IN BLACK AND WHITE.—"JUNIOR PHOTOGRAPHER" says

"I have a lot of black and white copying to do, and will thank you to give me a formula for a developer that will give great contrast. Hard white and black either for negatives or lantern slides. The formulas in the 'Year Book' are fairly good, but will not give density enough." In reply: For this class of work you should employ plates, such as are specially made for it, say, such as Mawson and Swan's photo-mechanical plates. If you use such plates, with the formula for developer supplied with them, you will have no difficulty in obtaining all the density desired. In future please write on paper instead of a post-card.

NON-RETURN OF NEGATIVE.—"NEGATIVE" writes: "I shall be obliged if you will kindly advise me on the following. Sometime ago I sent a 12 x 10 negative, of a large group, to a firm to have a bromide enlargement made from same, telling the Company to keep neg. for a few days, as I might want more, but I did not. So I sent my neg. to be returned, enclosing six stamps for postage. They wrote me that they did not know which my neg. was, so I sent them a print from same. Still no neg. came. I wrote several times, and at last they wrote saying it had been sent some time ago. I wrote again asking which way they sent it, if by post or rail, so that I might make inquiries about same, but cannot get an answer. I have lost £3 or £4 over it, as I have had a lot of repeat orders. In reply The only suggestion we can offer is that you sue the firm in the County Court for the value of the negative. Indeed, that seems the only course open to you.

ORNATE Mounting Cards are not Artistic.—The more ornate the card, the more it divides the attention with the picture. Scrolls, fancy cut-outs, and all manner of ornamental (?) double printing, is monkey business that detracts from the value of the real work—"Camera Craft."

The annual field day in connection with the Northumberland and Durham Federation of Photographic Societies took place on White Monday, when Bishop Auckland was visited. About 200 members and friends attended, and excellent arrangements had been made by the Bishop Auckland Society. By kind permission of the Lord Bishop of Durham, Auckland Castle and chapel were open for inspection. Various places of interest were also visited, and conductors for different places were appointed by the local society. Tea was provided at the Edgar Memorial Hall, and afterwards the annual meeting was held. Mr. J. T. Proud, president of the Bishop Auckland Society, occupied the chair, and the Bishop of Durham attended and delivered an interesting address. In welcoming the members of the Federation to Bishop Auckland, he said it had been a great pleasure to him to think that the house and garden and park of which he was the temporary occupant and trustee afforded the visitors considerable attraction. On the motion of Mr. Cowley (South Shields), a hearty vote of thanks was accorded the Bishop. The annual report of the Federation was submitted by Mr. Arthur Payne, and was adopted. Other votes of thanks concluded the proceedings.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography

The Oldest Photographic Journal in the World.

A PREFATORY NOTE.

I HAVE to thank the many able photographic writers who, in response to my invitation, have come forward on this unique occasion to join me in celebrating the Jubilee of THE BRITISH JOURNAL OF PHOTOGRAPHY. The size of the present number may suggest to the imaginative reader "what might have been" if I had accepted all the offers of assistance that were generously tendered to me, and my excellent friends, the Publishers, had complacently given me *carte-blanche* in the matter of paper and type. A Midsummer "ALMANAC" (without the advertisements) would have resulted!

A glance through the list of the contributors will show that many of them have been identified with the JOURNAL for twenty, thirty, and even forty years. But writers of the more modern school also assert themselves—in fact, they may be said to predominate. The aim kept in view in the compilation of this Jubilee Number has been to produce a publication which, when placed in the hands of an intelligent photographer who has not hitherto been a reader of photographic journals, shall so far attract him in some branch of his subject that he will become a permanently interested reader. In order to secure the suffrages of our undoubtedly great public not catered for by existing photographic periodicals, many thousand extra copies of this number of the JOURNAL are being printed. We shall signalise the possession of an inexhaustible fund of Jubilee energy and strenuousness by sparing no effort to bring the "B. J." before the notice of amateur and professional photographers in all parts of the world.

I trust that the articles and the number generally will secure widespread appreciation, and that an immediate result will be the enrolment under the banner of the "B. J." of several thousands of new readers and supporters. The history of the paper, which forms a feature of the number, is fairly complete, but of many of those identified with it in the long ago no trace or record now exists, and were it not that Nature has endowed the present Editor with a phenomenally good memory, even this story, brief and scanty as it is, could not have been written. Still, with all its shortcomings, I trust my readers will treasure it as a souvenir of the dear old paper, in association with which some of the happiest years of my life have been spent.

Well, now, in conclusion, just a little of the "personal touch," or "note," to impart the much sought and desiderated human interest to this brief chat between Editor and reader. I had for a long time set my heart on a Jubilee Number of the "B. J." and all promised well until a month ago, when a joint attack of influenza and septic poisoning prostrated me, and rendered me quite helpless. For weeks I was in a pleasing state of doubt as to whether I was to participate in the pleasure of seeing the Jubilee Number through the press. But a skilful doctor finally pulled me through—and so here is our number. "The Story of the BRITISH JOURNAL" was actually written in bed, and I think the pleasure of the work materially hastened my recovery.

I trust all readers of this Jubilee Number will become permanent supporters of THE BRITISH JOURNAL OF PHOTOGRAPHY.

THOMAS BEDDING,

Editor.

June 8, 1904

Entomological Photo-Micrography.

NO matter what part of the world we may find ourselves travelling through, and no matter if the temperature be above or below zero, we are sure to meet some denizens of the insect world. As we go northward into unknown Arctic regions, over the desolate wild "tundras," millions of gnats of many species dance at our lonely camp fires and torment us and the faithful animals that are carrying us through those wild regions. While we rest, almost gasping for breath, in the palpitating noontide heat of the tropics, we see innumerable insects flying, running, jumping, and crawling about, quite indifferent to the heat which saps our strength. But if we have a mind to study insect life, we need travel no greater distance than into our own garden or the nearest field, lane, or wood. Each has its own little world of insect life, peopled by those insects to which that particular environment is most suitable.

The changes, or metamorphoses which insects pass through from egg to perfect insect are most wonderful and varied. There is a romance to be found in the life of the most common and familiar insect which is food for thought and consideration, while to make a photographic record of that life history will be found to be a most fascinating and interesting piece of work. As well as the photograph of the living insect at various stages of its existence, a record should be made, by means of a series of photo-micrographs, of the remarkable anatomical changes which take place, and of the general microscopic structure of the insect under observation. It is with this section of insect photography—what may be termed Entomological photo-micrography—that I propose dealing in the space at my command.

The really keen photo-micrographer will find that Entomology will supply him with a vast number of interesting, beautiful, and instructive subjects, and none requiring a very elaborate outfit or a very high magnification. The magnification will range from about five diameters to two hundred and fifty diameters, and the latter will probably not be very often employed. The eggs of insects form particularly interesting and beautiful subjects for medium-power photo-micrography—from fifteen to twenty-five diameters generally yielding the best results. They must be treated as opaque objects and photographed with "dark ground" illuminations; either a spot lens or two lamps and "bull's-eye" condensers being used, but the latter will give the most satisfactory result, the eggs standing out from the dead black background in greater contrast and more evenly illuminated than with the spot lens. A wooden slide covered with dead black

paper will be found very useful as a mount and background, and to it the eggs attached to the twig, or whatever they have been deposited on, can be fastened with the aid of a pin. It is most undesirable to remove the eggs from their natural support, as, should the little germ within die, the egg will shrivel and greatly change in appearance. The lamps (two ordinary circular-wicked paraffin lamps will do admirably) should be placed one on each side at a slight distance from the stage of the microscope, and the "bull's-eye" condensers so arranged as to concentrate the light evenly over the subject, so that the eggs stand out in bold relief and free from heavy shadows. Both lamps and condensers will probably have to be shifted and fidgeted about a bit the first time this work

is attempted, but it is well worth while taking a good deal of trouble, the final result well repaying for it. Once the best position for lamps and condensers has been found, their exact position on the board should be carefully and clearly marked, so that they can be replaced on any future occasion without loss of time.

The preparation of the internal organs of insects for photo-micrography is delicate and interesting work, in which a deep half-plate developing dish will be found very useful. A thin sheet of cork, weighted to keep it from floating, is placed at the bottom of the dish, and the dish filled with water. To the sheet of cork the insect, previously killed with chloroform, should be fastened, on the ventral surface for the nervous system and on its back for the abdominal or thoracic viscera. The cork and insect placed in the dish filled with water, the skin is cut through on each side of the abdomen with a pair of fine-pointed scissors. With a little care the organs can be removed, washed in distilled water, stained with borax carmine for five to fifteen minutes, washed in several changes

of methylated spirits, finally in acidulated alcohol (about 1 in 10), thoroughly dehydrated in alcohol, cleared in clove oil, and mounted in Canada balsam. In this way very beautiful permanent preparations may be made. To obtain the gizzards of beetles and the salivary glands of cockroaches (the common so-called "black-beetle"), the freshly killed specimen is placed in a jar of water and left for a few days, until it begins to smell somewhat unpleasant, the contents meantime having been protected from dust by a cover of some sort. If the specimen is then removed, washed in clear water, and gently held between the fingers, it will be quite easy, with a pair of forceps, to pull off the head, which will generally bring away with it the oesophagus, salivary glands, and stomach, which can then be washed, stained, and mounted. It would

MARTIN DUNCAN.

Has successfully applied the cinematograph to the study of the movements of the lower organisms.

be out of place here to enter fully into all the details of the various methods of preparing parts of insects and entire insects for microscopic examination and photo-micrographing, but the reader who is wishful to gain more information on the subject will find it very carefully dealt with in the latest edition

plates, as I have invariably found them most carefully prepared and colour-sensitised and of first-rate keeping quality. In most cases the negative should be strongly built up, so as to give rather a hard contrasty appearance, but care must be taken not to over-develop and choke the fine detail. For

of "Modern Microscopy," by M. T. Coles and M. J. Cross. In Entomological photo-micrography, it is most desirable to use a suitably colour-sensitised plate for each subject, in conjunction with a screen, if the very best results are desired. Personally, I always use Lumière's series of orthochromatic

this reason, hydrokinone alone should be used with caution, as it tends to extreme hardness and blocking of delicate detail. One of the amidol group—Dianol, for instance—will be found to yield the desired result more easily.

F. MARTIN DUNCAN.

Journalistic Photography.

ALTHOUGH the close relation which now exists between the camera and the printing press was established little more than twenty years ago, it is noteworthy that photo-engraving formed the subject of experiment by Niepce some years before the first daguerreotype was given to a wondering world. In Niepce's process a metal plate covered with bitumen was exposed under an engraving, or in the camera obscura, and was afterwards treated with oil of lavender so as to make a resist, and the plate was subsequently etched with acid. It is quite evident from letters written by Niepce that this desire to produce engraved pictures by the action of light was uppermost in his mind when experimenting with the camera. Later on, Poitevin endeavoured to produce printing plates from daguerreotypes, and as early as 1852 our own Fox Talbot patented a process which he called phototypy. It is interesting to note that in this early process the English inventor employed what he termed a photographic veil - which is the prototype of the modern ruled screen. His "veil" consisted of a piece of folded gauze, and its object was to produce the effect of engraved lines or of uniform shading.

Other inventors improved upon Talbot's idea of a network screen, but none of them produced work sufficiently good to cause any uneasiness to the wood-engravers. But in France M. Gilot produced etched line blocks of such excellence that he encountered much opposition from those who saw in them a rival method of producing pictures from the Press, and the examples which he was able to show, and which brought him honourable mention at the Exhibition of 1855, were beautiful specimens of pen-and-ink, or line work. The original drawings were either made on the zinc, or transferred to the metal from paper; the photographic image direct on to the zinc plate did not come for many years afterwards.

We thus see that many were at work on the problem of producing a printing surface automatically without the use of the graver or the etching needle, but even those best qualified to judge never guessed that they were within measurable distance of a revolution in methods of illustration which would be entirely due to the use of the camera. About twenty-five years ago, even such an astute man as the late W. L. Thomas, one of the old school of wood-engravers, formed a school of wood-engraving as a feeder for the "Graphic" soon after that paper was started.

If we hark back for a moment to consider the method of producing a printing block which was in vogue up to the year 1866 or thereabouts, we shall be better able to appreciate the vast change which photography has brought about. The artist had to draw his picture on a boxwood block, and used a looking-glass in doing so, for the design had to be reversed. The drawing was executed either in line or wash, and, when in the latter, it was the engraver's duty to translate wash into "tint" or line. It thus came about that the engraver in the act of cutting the block destroyed the original by the artist, and much beautiful work was in this way utterly lost.

T. C. HEPWORTH, F.C.S.

Has had a very wide and varied experience of Press, lecturing, and photographic work.

Then came the first great change due to photography, and one which was welcomed by all. It became possible to transfer a photograph direct to the wood-block. This meant an enormous gain, for the artist could work on paper and in any medium which he preferred, and after the drawing had been photographed, and the photograph transferred to the boxwood block, the original was as good as ever, and represented a valuable asset. In the case of well-known artists, whose pictures could command long prices, the gain was great. If anyone cares to examine some of our back volumes in the period covered by the late sixties and early seventies many recipes will be found for transferring the photographic image to the surface of the wood. Only a few were satisfactory, for it was a necessity that the film should be so imperceptible that it should not flake off under the point of the graver, while at the same time the surface should not be hardened, or softened, or in any other way changed.

Mr. Carl Hentschel, whose name is honourably associated with the history of process work, described a method of transferring the silver image to the

wood-block in a lecture which he gave before the Society of Arts not long ago. The method was invented by his father, and was so ridiculously simple that he did not care to give it away by patenting it, but kept it as a secret process. He took an ordinary albumenised silver print, pasted it face downwards on the wood-block with a special adhesive of his own, and then rubbed away the paper with his finger by moistening it, just as one would do in the crystalum process. Like many other things, this highly useful and simple process was discovered by an accident, a silver print having stuck on a piece of wood, and the effort of detaching it showing how closely it had adhered to the surface. It

eed hardly be said that the delicate albumen film offered no obstacle to the graver, and that this simple and ingenious method of transfer at once gave the necessary reversed image in the wood-block. We may be quite sure that photography was blessed by many for the benefit which it brought to artist, wood-engraver, and to publisher alike in expediting the work of producing an engraving.

And even at this date the celerity with which a block could be produced had been greatly increased since the early days of wood-engraving. The system by which a single boxwood block was made up of a number of pieces bolted together, which could be separated so that each piece could be handed to a different engraver, was at the time of its introduction regarded as a wonderful thing. In Mason Jackson's "Pictorial Press: its Origin and Progress," written in 1885, there is an amusing account of the serious business involved in producing a small wood-cut. "I have heard the late William Harvey relate," he writes, "that when Whittingham, the well-known printer, wanted a new cut for the 'Chiswick Press' series, he would write to Harvey and John Thompson, the engraver, appointing a meeting at Chiswick, when printer, designer, and engraver talked over the matter with as much deliberation as if they were about to produce a costly national monument, and after they had settled all points over a snug supper, the result of their labours was the production, months afterwards, of a small wood-cut measuring perhaps 2 by 3 in." Contrast this leisurely way of conducting the business of producing a block with what Mr. Harry Furniss recently told of his experience in America, when he had to go through "the frightful ordeal of being interviewed at 12 o'clock by the members of the Press, and making a sketch;" and on arriving at the station two and a half hours afterwards he had a newspaper handed to him with his own drawing reproduced in its pages! This was a fine block, and a few years ago the production of such a thing so short a time was regarded almost as a miracle, a half-tone block taking far longer time. But now it is a common thing for a half-tone block to be made on an emergency almost as quickly, but such hurried work is not to be commended if the best results are expected.

The pioneer worker in half-tone work, if we pass over the old attempts of Fox Talbot and others with veils of gauze, etc., was Meisenbach, whose patent bears date 1882. For a long time the term "Meisenbach block" was commonly employed, but now "half-tone" block is generally applied to this method of illustration. The zinc line-block scotched wood-engraving, but the half-tone block absolutely killed it. As an example of the cost of preparing a wood-block for illustration, the present writer is able to draw upon his own experience. Many years back a friend requested him to get a drawing made upon a block which measured 5 by 4 in., and afterwards to get the block engraved, it being understood that the work in both cases was to be of the best. The artist received five guineas, and the engraver a similar sum, so that this small illustration cost exactly ten guineas. A half-tone block this size would cost nowadays less than as many shillings, while the saving of time would be enormous.

This is why the introduction of the half-tone block has been the means of actually creating so many new periodicals. It is a common thing for one of the cheap magazines to boast that it contains upwards of one hundred illustrations. Many of us wish that it didn't, for, truth to tell, ease of production has had the natural result of leading to much rubbish being palmed off upon the public. But there is an idea abroad that a photograph cannot lie, and that its artistic excellence cannot be open to question, and this is a very comfortable state of things to the publishing fraternity who produce cheap illustrated matter. If we would see half-tone work at its very best, we must open some of the American magazines, in which

a good deal of hand work is expended upon the blocks by artists, and where the printing is of the highest excellence. It is sometimes very difficult to tell whether some of these pictures are by process, or are clever examples of wood-engraving, but the use of a magnifying glass quickly sets all doubts at rest by revealing the regularity of the dots, while at the same time the tooling of the block by hand is plainly shown.

In mentioning the introduction of the Meisenbach block, it would not be fair to omit all reference to the work of Mr. F. E. Ives, whose name is generally more nearly associated with photography in colours. Meisenbach used a single-line screen, and reversed it during the exposure so as to secure the requisite effect. Ives used a cross line screen made by cementing two single-line screens together face to face. The name of Max Levy should also be mentioned as that of one who has carried the manufacture of screens, by means of his ruling machine, to the highest pitch of perfection. It may not be generally known that a large screen of this kind of the highest quality is worth not much less than its weight in gold. Credit should also be given to Mr. Ives, as well as to Dr. Eder and others, for elucidating the theory of the formation of the dot in half-tone, which has done so much to make practice efficient.

When the process-block first came into prominence it was loved by the printers as little as it was cared for by the wood-engraver, and, if these worthies could have had their way, they would soon have made an end of process and all its works. And if any of our readers are of that age when it is possible to recall the entry of the half-tone blocks, it will be remembered what a terrible mess the printers made of them. Printers who had been used to the comparatively deep trenches cut by the engraver looked upon these new-fangled blocks, with their delicate network of lines, the depth of which was not to be gauged save by a micrometer, as things impossible, and not to be regarded for one moment by a man with any self-respect. But the blocks were not wrong: it was the printers who were at fault. The ink, the paper, and the presses which would do excellent work under the old system broke down under the new, and, until each was overhauled and improved, the blocks were blamed. Printers, who thought at one time that they were hardly used in being required to deal with these half-tone blocks, will, if they are reasonable men, be the first to admit that their introduction brought great good, for a reform was then commenced which has had a most beneficial influence on the printing industry all round. A printing office, which not long ago was a synonym for all that was dirty, foul, and generally objectionable, is now as clean as any other place where work is carried on, and, if the printer aims at the highest class of work, it must of necessity be kept clean. The common use of the dynamo for driving the machinery, and of type-composing apparatus, naturally conduce towards this end.

Still more necessary is it for the printer to look to the cleanliness of his premises if he has any thought of taking up trichromatic printing, which we may regard as the colour-process of the future. At present, for reasons into which it is impossible to enter here, the photographic process has not superseded chromo-lithography, but we may feel sure that as improvements are introduced the three-colour method will gain ground. We have already seen some book-illustrations copied by this process from water-colour drawings which leave little to be desired; but it must be owned that really good work of the three-colour kind is the exception rather than the rule. The theory of the three-colour print is now thoroughly understood: it is when it is sought to reduce that theory to practice that difficulties crop up at every turn.

In a necessarily brief review of the connection which the past

half-century has brought about between photography and the Press, the names of many who have by their labours helped towards the work have been passed over, not intentionally, but for want of space to do justice to their merits. Collotype, Woodburytype, photogravure, and many processes of lesser note have been associated with Press work, but the zinc line

and the half-tone block have worked the actual evolution in our Press methods of illustration. For the same reason have avoided such details of manipulation as can easily be found in any of the text-books. We have written enough to demonstrate that the Press owes a great debt to photography.

T. C. HEFORTH.

Copying.

HAVING been kindly asked by the Editor for a short contribution to the Jubilee number of THE BRITISH JOURNAL OF PHOTOGRAPHY, I submit the following, which I hope may be of some assistance to the readers of the JOURNAL. Most photographers, both professional and amateur, have at times to make copies of something or other, and numerous devices have been put forward to accomplish this end. I have recently had a lot of copying, etc., to do, and evolved a piece of apparatus, of which the illustration is a photograph, which is at once simple, cheap, and always ready.

The illustration (Fig. 1) almost speaks for itself. The two uprights A are deal, 4 ft. long by 2 in. square; the two boards at top and bottom (B) are 18 in. by 9 in. by $\frac{1}{2}$ in., the top one having a slot in it vertically, 4 in. by $\frac{1}{2}$ in., thus giving an adjustment for the camera of 4 in. up or down; the two feet (C) are 22 in. by 6 in. by 3 in., and into these the uprights are let in with a shoulder. A carpenter supplied the wood, and planed it up for 8s. 10d. The metal part is just ordinary shop window fittings, obtained from Potter, in Aldersgate-street, at the cost of 8s. 4d., making the total cost only 17s. 2d. This consists of two brass-coated rods (D) 4 ft. 6 in. long, let into the base boards and secured at the top with two rings E screwed on to the wooden uprights. The arms F, on which to place the object to be copied, are of brass, 18 in. long, and fitting into sockets G, which can be adjusted to any height by screws, the same height on each side being secured by having the uprights marked in inches, as faintly shown in the illustration.

As shown, the apparatus is arranged for "shadowless photography," the object being placed on a sheet of clean glass, with a white paper reflector beneath it, this being all that is necessary for small objects, but for larger ones, such as that shown in Fig. 2, which is four inches and a half long and three and a quarter thick, it becomes necessary to have a reflector at the back as well, and this can be done by turning the lower

arms backwards, or a third pair of arms may be used if preferred, and using them as a rest for silvered glass, which can lean against the wooden uprights at the desired angle. This was the method adopted in this case, and it will be seen that the illumination is very even all over the large cone. The exposure for this was two min. at f45, bright light, Imperial Ord.

If an engraving, or map, or line drawing has to be copied, of course, the sheet of glass is not required, and the object, whatever it is, is laid on a flat piece of wood, which in

turn rests on the arms. By the kind permission of Messrs. Virtue and Co., proprietors and publishers of the "Art Journal" I am enabled to show a copy of an engraving of one of Turner's works (Fig. 3), "The Grand Canal, Venice," from their book entitled "The Turner Gallery," taken on an Imperial ord. plate at 11-30, 23-4-0, bright light, 1 min. at f. 32.

This last illustration was taken from a large heavy book, the page to be copied being laid quite flat on the board, while the pages beyond it were fastened with a piece of string to the uprights, and they will, I think, sufficiently indicate what can be done with the apparatus, which, when in use, stands in front of a window. By unscrewing and removing the two rings E it can be taken to pieces.

Of course, in copying, like architecture, the lines must be straight, and there must be no distortion, and, I think, it will be found that this is more easily accomplished, by such

an apparatus as I have described than by the perhaps more usual way, i.e., horizontal, and using an easel. At any rate I have found it distinctly better for copying a page from a book, and, comparing results, I find I can get more even illumination by this method than the other, having during this year alone used it for close upon 100 illustrations of various subjects, including black and white diagrams for the lantern. In this case, the diagrams were white on black photo-mechanical plates, lantern size ($3\frac{1}{2}$ by $3\frac{1}{4}$), being employed, the negative being used for the slide.

Picture Postcards.

PICTORIAL postcards are in evidence everywhere, scarcely a day passes without the postman dropping one into the letter-box, the children of every household have their postcard albums, the windows of the stationers in the remotest and smallest county towns show little else but postcards, plain or coloured; nay, the village shop has added them to its former stock in trade, which a year ago consisted only of needles, pins, reels of cotton, Quaker oats, penny packets of stationery, ink, and bulls-eyes. A new industry, in fact, has arisen just when it was wanted to give an impetus to flagging trade; can we not trace the recent rise in the price of securities on the Stock Exchange to the pictorial postcard? What further need is there of Tariff Reform, for has not photography and its latest offspring, the picture postcard solved the whole difficulty?

But I wish to treat the subject seriously and from a photographic point of view. The advent of the card is a boon to the idle snap-shotter and his friends. He can now print his negatives on cards and send them through the post instead of carrying his prints in a pocket-book. Who does not know the pocket-book, with its score or two of untrimmed, unmounted, highly-polished prints with a tendency to curl, which is, in season and out of season, brought out for the benefit (?) of friends? The photographer may also thank the postcard for the introduction of a new size of plate and camera. The plate, $5\frac{1}{2}$ by $3\frac{1}{2}$, differs little in area from the 5 by 4, a small size, which, though it has some advantages over the quarter-plate, has never become popular in this country, no doubt on account of its awkward shape. The new size does not suffer from this drawback. Its proportions differ little from those of the $7\frac{1}{2}$ by 5 plate, which, though still used, is generally said to be preferable in shape to the half-plate.

Of course existing negatives may often be used for printing postcards, as the shape and size of the picture need not be the same as that of the card, a suitable mask being used to protect the surface not occupied by the print; but there can be no doubt that the best results are obtained when the negative is taken with a view to its ultimate use. I think the ideal card should show a narrow white margin of, say, $\frac{1}{8}$ in. at the top and sides and 3-16 in. at the bottom; no space for writing on need be provided at the back, now that the Post Office allow half of the front to be used for the "communication." If the cards are preserved in albums, written matter by the side of the picture detracts from the appearance, and the commonplace and trivial communication is generally of little interest to any one. Thus it is best to occupy the greater part of the back of the card with the picture, though, of course, there is no objection to a wider margin than the one I have suggested. If the photographer does not possess a $5\frac{1}{2}$ by $3\frac{1}{2}$ camera, but only a half-plate one, he can easily buy or make of wood or stout cardboard carriers to hold these plates. Many plate-makers now

issue this size. In order to facilitate composing the view the focussing screen, a mask having a central aperture of $3\frac{1}{2}$ by $3\frac{1}{2}$ should be fastened to the ground glass; this is far better than ruling lines on it to indicate the limits of the plate to be used.

When the negative is finished there are many ways in which the printed card may be produced. It will, however, if prints are to be made by any direct photographic method, be necessary to mask the edges. I have found loose masks most troublesome to use, so I take lantern-slide binders and stick them down by their gummed surface to the film-side round the edges of the negative; by this means the print can, so to say, be trimmed, two strips if necessary being used if a wide margin is desired. If the strips project, say 1-16 in. beyond the edges of the plate, when frames other than those specifically made are used, there will be no difficulty in correctly placing the sensitive cards on the negatives, and no risk of light reaching the margins and discolouring them. If a large, or fast

REV. T. PERKINS, M.A.,
Has devoted great attention to the study and photography
of architecture.

large, number of prints is required, bromide cards, printed in artificial light, will be found convenient, and when once the correct exposure for any negative has been found, if the printing frame is always placed at the same distance from the light for each exposure, the prints are developed by plunging them into a tray of more of developer, giving uniformity in the prints. The prints are then secured, and the development is very rapidly finished. But if only a few prints are wanted from the same negative, some printing process will be more convenient. Self-toning cards, with little trouble, give pleasing results. There is yet another way of printing, and that is to use a process-block made from a negative, and the cards are printed in ink. The artistic process block-making has not reached such a high standard that if the printing is carefully done on good card, the results leave scarcely anything to be desired. The cost of a block of excellent quality is about £1 a guinea, and that of printing about 5s. to 7s. 6d. per thousand. The cards, ready for printing, are made in sheets, so that four, six, or more blocks can be printed at once, and the cards cut afterwards. It is evidently cheaper to print a number of blocks together than to print each block singly, as the time and labour required to print a sheet of four or more is greater than to print a single card. There is money to be made by photographers, whether professional or amateur, who care to turn their attention to pictorial postcard work. Publishing firms will buy negatives from which to print in bromide or silver prints with sole right to produce in half-tone in the form of cards, the photographer retaining the negative and copyright for all other purposes. Or the photographer may make blocks and have them printed to sell direct or through stationers. Of course to secure success the photographs must be good, and also of taking subjects.

T. PERKINS

Some Notes on the Telephoto Lens and its Use.

TELEPHOTOGRAPHIC lenses now play such an important part in both outdoor and indoor photography, that a short account of the development of the telephoto idea, accompanied by a few practical hints on the use of teleobjectives, will perhaps interest those who already possess such lenses, as well as those whose present interest in them is still purely speculative.

The parent of all telephoto lenses was the "Barlow" lens, which was presented before the Royal Society in 1834 by Peter Barlow as an appliance whereby the power of a telescope could be modified by altering the position of the magnifying lens without removing the eye or losing sight of the object. As no practical photographic process then existed, the Barlow lens did not immediately develop into a telephoto lens, and it was not until 1851 that the Italian scientist Porro photographed the eclipse of the sun in July of that year with the aid of Barlow's

working independently on the subject, Duboscq in France, Dr. Miethe in Germany, and Thomas R. Dallmeyer in England. The latter was the first to place a practical instrument in the hands of photographers, the formal announcement being made in a paper read before the Camera Club, London, on December 10, 1891, although previous notices had appeared as early as October 16 of the same year in the photographic Press. It must here be mentioned that in 1890 Steinheil constructed a telephotographic instrument for the German Government, but the fact was not published till later.

This first telephoto lens was composed of two cemented combinations, and somewhat resembled in external form the widely known Adon lens of to-day, but it had various defects, and, although the type is still adhered to by some celebrated makers, Mr. Dallmeyer realised that it was capable of vast improvement. Therefore, he took a rapid non-distorting photographic

Example of Low-power Telephotography (reproduced by permission of Colonel R. W. Shipway).

system, that telephotography became an accomplished fact, although a speedily forgotten one, for it is only within the last few years that the distinguished optician, Dr. Von Rohr, re-announced his discovery of it. The first clear reference to terrestrial telephotography is to be found in the pages of THE BRITISH JOURNAL OF PHOTOGRAPHY for 1873, when Mr. J. Traill Taylor, who then occupied the editorial chair, recommended the use of an ordinary opera glass for producing an image upon the ground glass, which was larger in proportion to the camera extension employed, than could be obtained with a positive lens of the ordinary type. The opera glass not being corrected for photographic work, caused the temporary abandonment of the idea, and nothing practical came before the photographic world until 1891, in the latter part of which year patents were applied for by three opticians who had been

lens for his positive and fitted it with a non-distorting negative, thus producing the telephotographic lens as we know it to-day.*

A curious error on the part of all the pioneers in telephotography was an idea that high magnifications were essential, and consequently the use of the telephoto lens was limited, both choice of subjects and loss of speed reducing the opportunities for its use. Early telephotographers never considered their lens as an aid to artistic expression, and limited their work either to mountains at twenty miles, or a weathercock whose image should fill the plate at one hundred yards. We know better nowadays, and it is the man who magnifies the image of his ordinary lens to three, four, or at

* For the earliest history of the telephoto idea the reader is referred to the interesting and valuable papers read before the R.P.S. by Major General Waterhouse

most five times its linear dimensions who is making the best use of the new power. Every day sees new applications of the telephoto lens—flower studies in natural size, portraits, surgical records, and, last but by no means least, illustrations of natural history make us query whether in the future the "ordinary" lens will go the way of the "ordinary" bicycle and give way to the telephoto lens as the old bicycle has given way to the "safety."

Regarding the practical working of the telephotographic lens, it must be pointed out that it is nothing more than an ordinary lens with an equivalent focal length far greater than what is commonly called its "back" focal length. Apart from this distinctive feature, a tele-objective does not differ materially from the lenses we have long been familiar with. It is rather in the unusual class of *subjects* which are attempted that any actual difficulty lies. We have not been accustomed to photographing subjects whose nearest shadows are from 200 yards to 20 miles' distance, and in many cases fail to appreciate the different conditions required for exposure and development. The different method of focussing also gives the novice an opportunity of going astray, as it is difficult for an operator, whose only practice in focussing has been obtained while working with a positive lens of comparatively short focal length, to immediately appreciate the enormous difference in sharpness which results from the slightest touch of the pinion controlling the separation of the elements of a telephoto lens.

It may be well to deal with the various operations of telephotography in succession, briefly pointing out where errors may creep in, and how they should be avoided.

Focussing.—The principal difficulty in focussing with a telephoto lens is found in want of light, and this difficulty increases as the degree of magnification becomes higher. In some cases it is difficult to pick up the image at all, although it is quite practicable to make a vigorous negative with this same amount of illumination. To make the most of the light there is, we should select the very finest possible ground glass and anoint it with a little vaseline or animal fat, wiping off the surplus until any trace of smeariness has vanished. Vegetable oils should not be used, as they have a tendency to oxidise and form a varnish, which in time discolours and is difficult to remove. The surface of a screen carefully selected and properly greased will be found on examination to be very different from the "loaf sugar" surface of the screens of commerce. A focussing magnifier is almost indispensable to the telephotographer, and it may be of high or moderate magnifying power as the taste, or perhaps rather the eyesight, of the user may suggest. For examination of the ground glass a low magnifying power is to be preferred, and it is very convenient to have it pivoted upon its base so that the edges of the screen may be examined with the eye-piece at an angle with the surface, thus intercepting rays which in the ordinary way would be lost in the tube of the magnifier. Where aerial focussing is practised by means of clear spaces upon the screen, a magnifier of high power should be used, as one of low power has too much "depth," and will show an object in focus at a distance from the desired plane. This method of focussing is of great value for rapidly obtaining an approximate focus, afterwards getting the greatest possible sharpness upon the ground glass in the ordinary way. Beware of hurried focussing. The slightest movement of the focussing pinion has an appreciable effect, and you may pass and repass the point of sharpness, simply through undue haste.

When long camera extensions have to be used, it is frequently necessary to have some mechanical appliance to operate the focussing pinion while the operator is using the magnifier upon the screen. The double knuckle joint arrangement at the end of a long rod, known as "Hooke's Universal Joint," and well known to users of astronomical instruments, is decidedly

the best appliance of its class, but it has the drawback being somewhat costly. Failing an efficient mechanical method, recourse may be had to an assistant who will gently turn the pinion backward or forward as he is directed. Many workers use the rack of the camera as a fine adjustment, moving it inch or so either backward or forward to ascertain whether best focus has been obtained. The writer has not, however, found any advantage in this method, preferring the very decided "jump" into sharpness of the "lens" method of focussing to the very gradual loss or gain of sharpness by the "camera" method. When taking a new tele-objective into use, it is desirable to test it for its chromatic correction. Many high-price lenses have an amount of chromatic aberration which does not affect their use per se, but which is fatal when they are used as positives in telephoto combinations. An ordinary new view and a low magnification afford a ready means of testing. Focus an easily recognisable object as sharply as possible and note whether it is as clearly rendered upon the negative. If any other object be found sharper, it indicates chromatic error which must be allowed for or eliminated.

In the earlier days of telephotography it was believed to be necessary to focus with the aperture at which it was desired to expose, but practice has shown that this precaution is unnecessary and that focussing may be done with the full aperture of the lens, such stopping down as may be necessary being done afterwards. When a colour screen or light filter is used, the image should be examined for sharpness after placing it in position.

Magnification and Working Aperture.—Obtaining these data has been one of the most common stumbling-blocks in the way of the beginner, and yet the process is a very simple one. To arrive at the degree of magnification given by a known camera extension, we have only to divide such distance by the focal length of the negative lens, and add one to the result. Thus when working with 10 in. camera extension (measured from the back of the negative lens to the plate) and a $2\frac{1}{2}$ in. attachment, we get a magnification of 5 diameters: $10 \div 2\frac{1}{2} = 4 + 1 = 5$. The focal length of the positive lens has nothing to do with the degree of magnification, but of course controls the actual size of the image. For example, with the extension given above, and still using a $2\frac{1}{2}$ in. negative attachment, if the positive lens had a focal length of 5 in., we should have an equivalent focal length of 25 in.; but with a positive with a focal length of 10 in., the equivalent focal length would be 50 in., or, in other words, we should have an image twice the length, although in each case the degree of magnification remains the same. To obtain any desired degree of magnification we have only to extend the bellows to a length corresponding to the number of times we desire to magnify multiplied by the focus of the negative lens, and to subtract once its focal length; thus with our $2\frac{1}{2}$ in. negative we wish to obtain a magnification of 8 diameters, and proceed thus: $2\frac{1}{2} \times 8 = 20 - 2\frac{1}{2} = 17\frac{1}{2}$ in. The intensity or working aperture of the combination is nothing more than the F value of the aperture of the positive lens multiplied by the magnification; thus F.11 with a magnification of 4 diameters becomes F.44, and so on with all other openings.

Exposure.—After having obtained the F value of the diaphragm in use for any particular magnification, over-exposure must be avoided. Every photographer should carry in his head or his pocket-book Howard Farmer's table, which begins with one second at 10 ft. and ends at thirtieth at a quarter of a mile and over, subject, aperture, light, and plate being the same. Isochromatic screens are almost indispensable in telephotography, and the same screen will affect the exposure with different plates in a different ratio. It is advisable to test a screen with the brand of plates it is to be used with, and a convenient way of doing this is to stop an ordinary lens

own to its smallest aperture, and, without using the screen, give an exposure which is decidedly on the side of under-exposure. Then, after placing the screen in position, expose plate in strips by drawing out the slide an inch at a time, giving exposures which are multiples of that given to the plate without the colour screen. The two plates should be developed in the same dish, as the first appearance of the image affords valuable information. Do not rely upon exposure meter tests with a colour screen, even if you are using ordinary plates, as the writer has found this method to be altogether untrustworthy.

Development.—As a rule, negatives taken with a telephoto lens, especially when the magnification is considerable, appear

flat and over-exposed almost from the commencement of development. The temptation to stop development on seeing the image cloud over should be resisted, and development should be continued until the negative appears very dense. On fixing, a bright image should appear, plus a slight veil which may be removed if desired with the ferricyanide reducer, or allowed to remain if rapidity of printing be of little moment.

In conclusion, it may be said that sharp images and soft ones may be produced at will, that hardness or flatness, and all intermediate stages may be secured with a telephoto lens provided that a little study is given to the conditions of lighting and exposure.

EDGAR CLIFTON, F.R.P.S.

Photographic Lenses of the Past Half Century.

FIFTY years have passed since the foundation of this JOURNAL, and a sketch of the progress in lens construction during that period may interest many of its readers.

When compared with the great advance in the sensitive-

ness of the plate, it may appear to some persons that the optician has not less progressive than other workers in the photographic world. A closer examination will show that the material at his command is more restricted and its nature more intractable. To this must also be added the mathematical difficulties with which the optician has had to contend. Few of the early lenses have survived, and the generation which used them is now almost of the past. The modern photographer has not had any experience of the drawbacks attached to those early lenses, and he has been spared the failures which would have made him more appreciative of recent progress. It is consequently desirable to draw attention to the lenses used fifty years ago and then to describe briefly the more important lenses, which have since been invented. In the early days of this journal the lenses in general use were the Petzval portrait and two varieties of achromatised single lenses. The latter were formed of a double convex crown, cemented to a plano concave, and a double concave flint. The rapidity of the portrait lens, then as now, was about f. 4, but it did not work to focus. In other words, the light which affected the plate was focused in a different plane from that of the image seen on the reversing screen. It was not till 1858 or 1859 that this defect of the portrait lens was remedied. Other defects also existed in the lens, the area of good definition was very small, there was much astigmatism, and the field was round. This last defect, however, must be regarded from the standpoint of the work to be

done. For portraiture the photographer knows how to take advantage of it, to add to the charm of the picture, but for copying is most detrimental. As the other two lenses were single landscape combinations, it will be understood at what disadvantage the photographer was placed in copying. But notwith-

standing its defects, the portrait lens of Petzval was a brilliant optical achievement. Slow photographic processes then prevailed, and made the use of rapid lenses imperative. Petzval's invention at one stroke reduced exposure to less than a sixteenth of the time necessary with a landscape lens. For bust portraits the quality of the image of the portrait lens is very pleasing, and it is therefore not surprising it has withstood keen competition for over sixty years and that it is still preferred by a large number of professional photographers. The portrait lens, however, was not Petzval's only lens. He conceived the idea of the Orthoscopic for landscape purposes about the same time, and after the regrettable quarrel between him and F. Voigtländer, again took the lens in hand and introduced it in 1857. The aperture was about f. 8, but the lens suffered from want of rectilinearity. It found many friends, nevertheless. One point in the construction is deserving of special note. The lens has a positive front and a negative back combination, and it works at a much shorter back focus than would a single lens giving an image of the same size. The Orthoscopic is, in fact, a telephoto combination deprived of variable focus through fixed dis-

PHILIP EVERITT

[Furley Lenses.

Has in recent years devoted great attention to the subject of photographic optics.

tance of separation of the lenses. A just estimate of the work of J. Petzval, as a theoretical and constructive optician, should assign to him a very high position in photographic optics. In 1860, J. H. Dallmeyer introduced the triplet bearing his name. It was a successful attempt to solve the problem of adding recti-

tance of separation of the lenses. A just estimate of the work of J. Petzval, as a theoretical and constructive optician, should assign to him a very high position in photographic optics. In 1860, J. H. Dallmeyer introduced the triplet bearing his name. It was a successful attempt to solve the problem of adding recti-

linearity of image to the other properties opticians had combined in the photographic lens. The objective was a commercial success, and seems to have spurred Thomas Ross to the improvement of the Collen lens, brought out by his father. The Collen principle was retained in the Actinic Doublet, but the two achromatised meniscuses received more curvature and were placed closer together to include a wide angle of view. About the same time J. H. Dallmeyer introduced his rapid landscape lens, a single cemented combination, formed of two crown meniscuses enclosing the flint. The constructor was brought into controversy with Thomas Grubb by the claim for superiority of the new lens. Thomas Grubb, in 1858, had introduced the applanatic landscape lens, which was much appreciated by photographers, and with so good a lens it is not surprising that he should have disputed J. H. Dallmeyer's claims. In 1865 the first of the Steinheil photographic lenses made its appearance. This was the Periscope, a combination formed of two unachromatised meniscus lenses. It covered a very wide angle, and gave an image of highly satisfactory rectilinearity; desiderata which the photographer much appreciated. In the following year an actinically corrected achromatised series, called the Aplanat, was introduced. This lens, whether as the Aplanat, the Rectilinear, the Symmetrical, the Euryscope, or any of the other names manufacturers have given to it, bids fair to enjoy as long a life as Petzval's portrait combination. Some thought the fate of the Aplanats was sealed when the anastigmats were invented, but time has shown that they are sufficient for a large portion of the work the photographer may have to do.

The gradual advance of German opticians to the front rank is no doubt due to their patient, scientific work in calculating lenses, instead of trusting to the empirical methods which prevailed here. The valuable contributions to photographic optics by the late Professor L. von Seidel, a very able mathematician, were undertaken at the instigation of the firm of Steinheil, and we are indebted to the late Dr. Adolf Steinheil for a number of lenses of great merit, some of which are of striking originality. All these lenses were the result of calculation. It seems certain that Adolf Steinheil had full knowledge of the conditions necessary to the construction of the anastigmat. The antiplanatic lenses are proof of this. Notwithstanding the want of suitable glass, he succeeded, by an ingenious device, in applying those principles and though the result left much to be desired, a distinct improvement in the correction of astigmatism was realised in these lenses. If the rectilinear landscape lens of T. R. Dallmeyer be added to the list, we may say this ends the period of construction with the old crown and flint glasses.

Some reference should here be made to the events which were taking place at Jena. In 1846 Carl Zeiss founded an optical business in this old university town, and after some years made it his chief aim to perfect the microscope. He saw it was necessary for the purpose that he should secure the co-operation of a first-rate mathematician, and, after one unsuccessful trial, had the good fortune to secure the help of Professor Abbe. The important progress in the microscope, since Professor Abbe devoted his energies to it, is generally known. Abbe was forced to the conclusion that further progress in optical instruments depended upon the production of suitable varieties of glass, a conclusion also foreseen by Petzval and von Seidel. With the assistance of Dr. Schott, the son of a glass manufacturer, experiments were made. These were of such promise that a small factory was established at Jena. The Prussian Government, by granting a subsidy, supported it during a short period, and in 1888 a number of new kinds of glass were placed at the disposal of lens makers. The late Dr. Hugo Schroeder was the first photographic optician to make practical use of the new material by employing one of these varieties for the construction of the now obsolete Concentric lens. Its flatness of

field and freedom from astigmatism, recommended the lens to photographers for a short period, but it had no chance of prolonged success in competition with the more rapid Protar which soon followed. The firm of Carl Zeiss, after applying new varieties of glass to the microscope, turned its attention to photographic lenses. At first Professor Abbe sought to better these instruments by making them apochromatic, but it was soon found that the cure of astigmatism was of much greater importance, and Dr. Rudolph worked in that direction. In 1890 the first of the Carl Zeiss anastigmats was introduced, and it marked the beginning of a new period in photographic optics. These lenses are now known as the Protars. They cover a large field of view, which is flat and well corrected for astigmatism as well as the other errors which are compensated in the Aplanats. Although none of the series have the rapidity of the Petzval portrait lens, the excellence of their performance, added to the rapidity of the modern dry plate, brings them almost to the standard of a universal lens. The Protars may be looked upon as forming one group of anastigmats with a common feature of construction. They are unsymmetrical doublets with cemented surfaces performing different functions in each combination. Both halves are positive achromats, but the glasses and their form are such, that spherical aberration is corrected by the front combination, and astigmatism by the back. In the series with the back combination formed of three elements the correction is more perfect, but the underlying principle of construction is the same. The Double Protars must be regarded primarily as a series of single lenses. They are corrected similarly, but in uniting the two combinations of the simple Protar to form a single lens, the front half has been turned round and cemented behind the back. These single lenses may be used separately or combined to form doublets. When used in the latter form, they may be looked upon as connecting link between the Protars and the cemented symmetrical anastigmats, which comprise the Goerz Double Anastigmat, Steinheil's Orthostigmat (Type II.), and the Holostigmat recently introduced by Messrs. Watson and Sons. Here we have a striking instance of the similarity of direction inventors' minds may take when a given problem has to be solved. The lens, known as the Goerz Double Anastigmat, was the independent invention of at least three opticians—Emil von Hoegh, Dr. Steinheil, and Dr. Rudolph. In applying for the patent Emil von Hoegh secured priority. The three lenses depend upon the same principle of correction that is used in the Protars, but instead of curing spherical aberration in one combination and astigmatism in another, both corrections are effected in a single combination of three elements, the middle one of which combines suitably with the other two. The opposition of two of these compound lenses to form a doublet corrects distortion as well as residual errors. Messrs. Ross, Limited, manufacture the Zeiss and Goerz lenses under licence, and Messrs. R. and J. Beck, Limited, the Steinheil Orthostigmats (Type II.) It should be mentioned that a similar instance of concurrent invention happened in the case of the Orthostigmat (Type II.). Dr. Kaempfer, at Messrs. Voigtlander and Son's, was also calculating this lens, but Dr. Rudolf Steinheil anticipated him and obtained the patent. The right to manufacture was, however, granted to Messrs. Voigtlander by Dr. R. Steinheil, and the lens is made by them and known as the Collinear. Passing from this group, another, in which air spaces are introduced in the combinations, claims special attention. I am inclined to think that a feature in the lens, invented by our countryman, Mr. Dennis Taylor, may have been instrumental in directing the attention of German opticians to air spaces as elements of construction. The Cooke lens is primarily a triplet, and unlike other lenses of that class, there is no perceptible flare or ghost. This fact removed to some extent the prejudice against lenses with more than four reflecting surfaces. The Cooke lens became

very popular, notwithstanding its limitations, and brought the inventor much praise from Continental opticians, because of the principle of construction upon which it rests—that of giving the lenses a form which dispenses with diaphragm corrections.

In 1897 the Planar was introduced by the firm of Carl Zeiss. This was the first of the anastigmatic doublets, in the construction of which air spaces were used. Dr. Rudolph's object was to apply the Gauss principle of correction to photographic lenses. Another feature of the lens should also be noted. The two cemented elements in the combinations are hyperchromatic. The cemented contacts have scarcely any effect beyond altering the dispersion. A compound lens may be thus obtained of the refractive power it would possess, if made of either material, but the dispersive power is different. The Planar, in its freedom from spherical aberration and astigmatism, is a very perfect lens, and its construction appears to have suggested two others to Dr. Rudolph—the Unar and the Tessar. In the Unar construction, spherical correction, as in the Planar, is combined with astigmatic correction, as in the Protar. The combinations are formed of uncemented elements, and the lens is unsymmetrical. The Tessar resembles the Unar in having an uncemented negative front combination, but differs from it in having a cemented back combination like that of the simple Protar. Various other anastigmats, in which air spaces are used, have also been invented. Four may be instanced to give some idea of the many possibilities of combination. The homocentric, recently introduced here by Messrs. Ross, is a double combination corrected on the Gauss principle. The Busch Anastigmat resembles it in construction, but instead of abnormal pairs of glasses for the combinations, normal pairs are used. In this respect the latter lens resembles one constructed by Alvan Clark. The firm of C. P. Goerz has introduced a lens resembling the Orthostigmat (Type II.), but differing from it by the substitution of an air space for the middle-glass element in both combinations. The Unofocal, invented by Dr. Rudolf Steinheil, might at first sight be taken for the same construction, but it involves different principles. The glasses used, both crown and flint, are of the same refraction, and their foci are also the same. In the Goerz lens an abnormal pair of glasses is used, but in the Steinheil lens it may be said that neither a normal, nor an abnormal pair is used. This is a new departure.

It has been shown that the cemented anastigmats may be subdivided into two groups, the symmetrical and the unsymmetrical, and the same may be said of the uncemented anastigmats. But besides doublets, we now have triplets, for Messrs. Voigtländer, under the direction of Dr. Harting, have introduced two constructions of this kind under the names Heliar and Dynar.

Although the work of Mr. H. L. Aldis has been reserved until

that of subsequent inventors has been described, it is equally deserving of notice. This optician became known through the Stigmatic lens, which he calculated for the firm of J. H. Dallmeyer, Limited, and it has enjoyed considerable popularity. The construction is rather complicated, but a new lens bearing his name, which has been issued since his departure from that old-established house, shows that his work has been in the right direction, that of simplification. It should be remembered that the modern lens requires great exactitude of workmanship, more especially when air spaces are used in the scheme of construction. It is therefore of much importance, not only with regard to cost, but also for freedom from error, that the lens should be as simple as it can be. The lens recently introduced by Mr. Aldis has three elements only, two of which are cemented together. For simplicity of construction this surpasses even the Cooke lens. Yet simplicity should be subservient to correction.

It would be hardly right to close this outline of the history of photographic lenses during the past fifty years without mentioning the telephoto combination. Such a lens may be formed by uniting two positives, or a positive with a negative. There is no doubt that Porro was the first to use the combination for photographic purposes, the type adopted by him being a positive united to a negative lens. This was in 1851. The late editor of this journal, J. Traill Taylor, prevented the combination from being forgotten, and when Mr. T. R. Dallmeyer, at the suggestion of Dr. P. H. Emerson, revived it, the discussion as to priority of invention between him and Dr. Miethe, who was then with Messrs. Voigtländer, disclosed the fact that Dr. Hugo Schroeder and Dr. Adolf Steinheil had made telephoto lenses some time before. The slowness of the wet plate process probably stood in the way of the Porro lens, but the rapidity of the dry plate was favourable to the revival of the combination, and a growing sphere of usefulness now seems to be open to it. Some very charming portraits have been produced with the lens, and it is even gaining ground as an adjunct to the hand camera.

All the lens combinations which have been invented during the last half-century have not been mentioned in this sketch, but I trust that those I have selected will give the photographer an idea of what has been accomplished, and make it clear how great is the debt we owe to the few men who have made photographic optics their study. The interest the successive editors of the BRITISH JOURNAL OF PHOTOGRAPHY have hitherto shown in regard to the lens makes the paper a valuable record of the progress in photographic optics, and in sending you my best wishes for continued prosperity, I hope that interest will remain an important feature.

P. EVERITT.

Some Experiences with Celluloid Films.

It would, perhaps, be difficult to indicate a more striking instance of the remarkable popularity to which the practice of photography has attained during the last year or two than is to be found in the use of celluloid films, and the compact and perfect cameras now so readily obtainable and which render their manipulation so easy to the uninitiated.

But this excessive simplification of photography—if I may be allowed to use such a phrase—has, it seems to me, created quite a distinct type of amateur, who personally contributes nothing to the production of the photograph beyond the mere "pressing the button," to use that which has now become a popular phrase in everyone's mouth.

Indications, however, are not wanting that the more serious class of amateur workers, and those to whom the title is more properly applicable, have been, and are, attracted by the many obvious

advantages of film photography to adopt that method of working in preference to the use of glass plates; and, as this tendency has recently considerably increased, due in part doubtless to improvements in the manufacture of the films themselves, some hints and suggestions, gleaned from the practical experience of two years' experimental and practical working, may be of interest to some readers of the Jubilee Number of THE BRITISH JOURNAL OF PHOTOGRAPHY.

Now, the first question that is not unnaturally put by those seeking for information upon the subject is: Are films as reliable as plates? My answer is that if good films are procured, and reasonable precautions observed, films are as trustworthy as glass. Obviously, on the first head, it is impossible for me to give any useful information without running the risk of an action for libel; but the purchase of a few packets

or spools of film of different makes, and a careful comparison of the resultant negatives, will go far to remove any doubts on this score. It is a fact, however, that although a very great general improvement has taken place in the manufacture of films, some makes are still of superior quality to others.

I would warn the intended exponent of film photography not to be discouraged by the mysterious shortcomings and defects sometimes alleged against films, many of which have no foundation in fact, and would, indeed, apply with equal force to plates, and are, in truth, due to want of skill and experience on the part of their users. This is, of course, no matter of surprise when it is remembered that so many commence the practice of photography with films, and necessarily lack the technical knowledge that would enable them to avoid many of the defects of which they complain, and which they regard as inherent in the films themselves.

Films are not faultless, nor are plates, but the former are often far more rigidly criticised for failings than are the latter. As an instance of this I found last summer a batch of films exhibiting curious irregular markings which at the moment I could not account for. In the course of my investigations I exposed some rapid plates under as nearly as possible similar conditions, and developed them with the same developer, metol-hydroquinone, and met with precisely the same defects. After further experiment I found the cause to be two-fold: (1) The employment of an inferior sample of sulphite of soda; and (2) allowing the films to remain stationary in the developer. I may say at once that although widely recommended, I do not regard metol-hydroquinone as a suitable developer for celluloid films. Apart from the production of markings, which not infrequently occur, it also tends to produce a coarse, granular image, and the negatives lack that roundness and gradation which are obtained with comparative ease with the pyro-soda developer, which I regard as emphatically the best all-round

developer for film work. In making up the solutions, whatever be the developer employed, the anhydrous form of the sulphite salt should invariably be employed. It is somewhat more expensive, but as only half the quantity of the ordinary variety is needed, the pocket is not seriously affected.

It is necessary to refer to one very serious charge which is frequently alleged against films, and that is their supposed lack of keeping qualities. But here, again, a good deal of misapprehension appears to exist in the minds of those who use plates, and who rely for their information upon what they are told by others. It is not an unknown thing for plates to deteriorate under improper or unsuitable conditions, nor are films immune from such disabilities. But given proper precautions as regards the obtaining of fresh films, and their subsequent careful storage, no apprehension on this score need deter the careful and conscientious worker from adopting them. Some films appear to possess superior keeping qualities to others; but

with all special precautions must be taken to preserve them from the deteriorating influences of damp, and the fumes produced by the burning of gas. This is best secured by storing them in an air-tight box, or tin, constructed on the platinum paper, calcium storage-tube principle. There is no extra difficulty, and very little expense, in adopting this plan; for either at home, or when travelling, some provision must be made for storage, and the adoption of this method will prove an effective safeguard against the deteriorating influence of damp. Care should, of course, be taken when purchasing to see that the films are fresh, and have not been kept in a shop under unsuitable conditions for a longer or shorter period. Most manufacturers assist the consumer in this respect by printing the date of issue on the packet or spool; and, as regards the second danger, I make it an invariable practice to order films direct from the makers, and even should I run short whilst on tour

I get a fresh supply mailed rather than run any risk of getting stale material from a local source.

I think it an advantage, in all events with roll films, to develop as soon after exposure as possible, as the films then seem to be more susceptible to any possible deteriorating influences. Roll films, by this way, would appear to be less likely to be so affected than flat films, as the tight winding and protective influence of the backing paper must afford a greater degree of protection than is possible in the storage and packing of cut films. The development of roll film when all the exposures have been approximately uniform is a simple and expeditious operation; but to find it an easier matter, when the films are quarter-plate, or larger, to cut the spool into two and develop each half separately. The practice, often advocated of developing several films superimposed in one dish should be studiously avoided, as it is the cause of many failures, including uneven development, spots, patches, and markings of all kinds due to the unequal action of the developer.

JOHN A. HODGES,
Formerly Hon. Sec. of the Royal Photographic
Society of Great Britain.

I am aware that the plan is recommended by the film makers in their instructions, but they would, in their own interests, be well advised to entirely delete it. The system, as a time-saving device, is, of course, very attractive, and, because of that fact, I have given it a considerable trial; but the experience so gained compels me to condemn it in the interests of film photography in the strongest possible terms.

In the space at my disposal it is impossible to say much about development; but I have found that most of the published formulae give a softer and better type of negative if diluted with at least a third more water than the amount stated in the directions. But on two points with regard to the after-treatment of films usually advised, I desire to give a word of warning. The glycerine bath in which it is recommended to soak the films after fixation, although undoubtedly effecting the object of reducing the tendency to curl, at the same time so greatly increases the hygroscopic condition of the

as to induce a condition of things far more serious and detrimental to the life of the negative than the evil which is intended to remove. The curling of rollable film, although somewhat perplexing at first, is a matter which soon ceases to be annoyance, and one that may be reduced to a minimum by pinning the films by the four corners to a blotting-board, allowing them to dry, and then immediately placing them under pressure.

Another point in which, in my experience, heterodoxy seems to have the advantage of orthodoxy is in omitting the customary alum bath after fixing. If fixation has been, as it should be, thorough (and films always require more careful treatment in the fixing-bath than plates, owing to their tendency to float and rise above the surface of the solution), and the washing is complete, the necessity for the alum bath does not arise, and on occasions serious disadvantages, very often causing the film to split and leave its celluloid support.

Of the advantages of films, and particularly the rollable variety, it is almost unnecessary to write, for they are self-evident. Speaking personally, I have found them the greatest boon in lightness and portability, making that which was formerly a labour a pleasure. Much of my photographic work consists in photographing a district or tract of country with a view of securing a pictorial itinerary to be afterwards used for lecturing purposes, and when the district selected happens to be, as is frequently the case, of a mountainous or rugged character, the fatigue involved in carrying even a quarter-

plate camera, with half-a-dozen slides, and the usual necessary impedimenta, is considerable, and the substitution of rollable film for glass plates on such occasions has, as I have already said, converted that which was formerly a toil into a pleasure.

Speaking of the results, which, after all, to the serious photographer is the main consideration, whilst I have had many failures, due for the most part to my own want of care, or lack of special experience, I cannot find any material difference in the quality of the slides produced from my film negatives and those made on glass plates; and in order that you, my readers, may form your own judgment on this point, I am submitting to the Editor with this article several prints from roll-film negatives, which I hope he will find room for, by way of illustration to this article.

In case I may have been misunderstood in what I have said about the keeping qualities of celluloid films, more especially as *THE BRITISH JOURNAL* has so wide a circulation abroad, it is perhaps necessary to add that my observations refer solely to the use of films in the British Islands, to which latitudes my experience is confined. Of their keeping qualities under more severe climatic conditions I cannot speak personally; but from what I learn from those who have used them abroad it would seem that a dry heat has no deleterious effect, but danger is to be apprehended when a high temperature and a humid atmosphere are encountered; but it must not be forgotten that very few glass plates pass unscathed through such adverse conditions.

JOHN A. HODGES, F.R.P.S.

Some Notes on the Past, Present, and Future of Stereoscopic Photography.

TO the gifted Editor of this JOURNAL I owe the encouragement which first led to my taking an active interest in the subject of stereoscopy. Himself a past master in this branch of the photographic art, his teaching and example fostered my enthusiasm, and ultimately gave me confidence to undertake a journey through Egypt, Palestine, Syria, Turkey, Greece, and Italy, for the sole purpose of collecting stereoscopic illustrations of some "regions of old renown," and of the life of their present inhabitants.

I trust this explanation will make my offer of the following notes to his Jubilee Number appear less an act of presumption than venturing upon ground already traversed by my friend than grateful acknowledgement of my indebtedness to his able guidance.

We find on looking back into history that binocular (or stereoscopic) vision is no new thing. About 2,000 years ago Aristotle studied and wrote on binocular vision, as also did Galen, and 1,500 years ago treated the subject even more fully than Leonardo da Vinci (1452-1520) is stated by some authorities to have been the first to suggest the principles of binocular vision, but it was also known by other painters and physicists. Photography not being then in use, geometric diagrams were made as "slides," and continued to be used until the time photography came and enabled workers to make a larger variety of more pleasing pictures.

Professor Charles Wheatstone, in 1838, devised the first stereoscope, and described it in "*Philosophical Transactions*." Wheatstone's theory was that if two plane pictures were made of an object from the positions as seen by each eye separately, and the two pictures were superimposed, they should appear to the eyes to give the same relief or solidity as the object itself.

He constructed an instrument in which two mirrors are mounted at right angles in the centre of the stand, at each end are carriers to take prints, and the positions of these can be adjusted by means of screws at the base. By placing one of the pictures in each carrier they can be adjusted so that their reflections from the mirrors pass through the two openings (sometimes fitted with lenses to magnify the picture) in front where the eyes are placed, and these reflections coalesce or blend apparently behind the mirrors.

Prior to this we find no trace of the stereoscope itself. None probably were used, for proper stereoscopic effect may be obtained from a print without the aid of a stereoscope, as described by the Editor in a paper read by him at the Gloucester Convention in 1899, and reprinted in these pages.

Taking events chronologically, we find that, simultaneously with Wheatstone's invention came Daguerre's discovery of photography; but there were no Daguerreotypes made for the stereoscope until 1845. When the Daguerreotype was first applied to the stereoscope it became all the rage, and when opening the great London Exhibition of 1851 the late Queen Victoria showed her appreciation of the two inventions by sitting for a three minutes' exposure; with her Majesty were also the Prince Consort, Napoleon the Third, and Empress Eugenie.

About a year previous to this event, however, Sir David Brewster suggested lenses instead of mirrors for combining the two pictures, and he made the well-known and old-fashioned simple box-pattern, with lenses at one end, a place to slide the pictures in at the other, and an opening at the top to let in the light. The lenses thus used slightly magnify the picture, and produce the desired result by refraction instead of reflection. Brewster, who died on February 10, 1868, at the age of eighty-seven years, probably did more than anybody else

to popularise the stereoscope, and his book on the subject is as well—if not better—known than his "Life of Newton" and "More Worlds than One."

At the time of the exhibition mentioned above stereoscopic photography began to make headway. Duboscq, of Paris, took up the work, and made the slides commercially and exhibited them there; he also made a stereo-microscope. The French have always been ahead of us in stereoscopic matters, and others who took up the process were Ferrier, Soullier, and Clousard, all of whom in the end joined forces and turned out work of the finest quality, and obtained prices ranging from 12s. 6d. to 21s. each for their transparencies by the albumen process. They also came to photograph the interiors of Buckingham Palace just before the death of Prince Consort, and gave as much as three days' exposure for some of the rooms.

About five years before the first issue of *THE BRITISH JOURNAL* (under its old name) appeared, stereoscopic portraits began to be the craze, and some of the best-known men—T. R. Williams and A. Claudet—charged as much as two and a-half guineas for their stereo-Daguerreotypes, with extra for tinting. At the end of the fifties most photographers were doing stereo portraits on paper and getting fancy prices for them. This went on and on, with the result that in 1862 stereoscopic photography was at the zenith of its popularity, and for many years held its own. Stereoscopes were to be found in almost every drawing-room.

William England, one of our greatest authorities and ablest of stereo workers, has said that at the Exhibition of 1862 stereoscopic pictures were the most popular form of souvenir, and the sales ran into six figures. He further states that "ninety-five per cent. of the views sold were for the stereoscope, and of the many popular subjects I myself produced from ten to fifty stereoscopic negatives of each, which were always kept printing." Of two favourite pieces of statuary it is on record that he had a hundred negatives of each.

Unnecessary costly, and clumsy into the bargain, the hand form of the instrument was gradually superseded by the much more convenient cabinet pattern, with facilities for the ready mounting and changing of fifty slides or upwards on an endless revolving band, each slide being brought into position by simply turning a knob. But even this improvement did not long avail to save the stereoscope from practical desuetude. Its relegation to the limbo of discarded trivialities was probably due to two main causes, at the latter of which it may be instructive to cast a retrospective glance.

"The first, but minor, cause was the costliness of both instruments and slides. Our own first hand stereoscope, box-pattern, represented an outlay of exactly two guineas; our last cost one shilling and sixpence. We prefer to use the latter, though we exhibit the former.

"The prices charged for slides, as we previously stated, were

also high; but costliness alone would not have proved a deterrent to the continued vogue of the stereoscope.

"The second, and principal, factor in its overthrow was inferiority and indecency of the slides, due, undoubtedly to rapacity and unscrupulousness of the ordinary 'professional dealer' of days gone by. It was all in his hands, and had been content with a fair margin of profit that would still have enabled him to supply the work of able and conscientious practitioners, all would have gone well. But let us examine carefully any old collection of slides, and what do we find? When not vulgar, replicas from the same negative are not infrequent, while slipshod adjustments and slovenly mounting are the rule. Even when artistic taste or knowledge had any part in the selection of subjects (which was frequently the case), the work itself appears to have been shockingly scamped. Insufficient attention to washing and

the purity of materials are abundantly evident from the usual results. Meanwhile, instruction in drawing and other branches of graphic art is becoming universal, and published results of various pictorial reproductive processes were combining with the influences of increasingly frequent exhibitions of painting and sculpture to raise the general standard of taste, and educate the rising generation to some of the essentials of art. No wonder that the wretched productions we have spoken of found little favour with the higher intelligence of a later day."—J. Ashby, in the "Photographic News," August 16, 1901.

There is danger looking ahead again now, for only a week we saw exhibited in a well-known dealer's stereoscopic pictures of a very dubious character. This sort of thing is not to be encouraged, or it will certainly prevent the stereoscope again becoming popular in the best society.

We must not be understood as condemning indiscriminately professional workers of the past. We have alluded to honourable exception, and the names of Cooper, Wilson, Bedford

England, Goode, and Blanchard claim distinction as those pioneers and honest enthusiasts in stereoscopic work, and many others might be mentioned who were distinguished well for artistic taste as for thoroughness in their method of production. But for one who worked conscientiously for love of his art there were hundreds who had no higher aim than to utilise a popular fancy for the turning of the nickel shilling.

Let us now hark back a little and see what progress has been made in cameras during this time. In the very issue of this journal we find several references to stereoscopic photography. At a meeting of the Liverpool Photographic Society, held on January 3, 1854, a camera, invented in Paris for taking binocular pictures, was described by Mr. Burges. It carried two lenses so as to take two pictures at the same time. It was called a "Quintoscope." This is actually

P. R. SALMON, F.R.G.S.,
Editor of the "Photographic News."

reference I can find to two lenses being used at one time. S. F. Mascher's camera, having one lens only, which could be moved from one side to the other, is in the same issue described to be the most perfect camera on the market, and another method in the same issue is that of converting an ordinary half-plate camera by means of a sliding front, and a clumsy zinc arrangement in the dark slide for exposing the plate one half time.

Other cameras mentioned are by Cartwright, Abraham, and the moveable bar method of Latimer Clark, which has been often described in these pages and in the almanacs. The "single-camera" method is largely in use even to-day, and a number of adapters for using single cameras for making stereoscopic pictures are on the market.

Although the first "instantaneous" photograph was taken in the early fifties, some considerable time elapsed before instantaneous stereoscopic pictures could be taken, chiefly because of the necessity of moving the position of the single cameras, and it was not until the "side-by-side" cameras came into use that instantaneous work became possible. I may here remark in parenthesis that in Robert Hunt's "Handbook of Photography for 1851" I can find no mention of stereoscopic photography, but in the 1853 edition "it is thought advisable to devote a short chapter to some notice of it." What he does say is interesting, and I regret the space at my disposal will not allow me to make extracts.

The neat folding pocket stereoscopes of to-day are not so new as they may believe they are, for early in 1855 Mr. S. F. Mascher, Philadelphia, took out a patent for a locket containing two lenses and supplementary lids for pictures. The lenses were hinged on one side and the lids on the other of a frame like a watch-case, and they shut up one within the other like a locket.

The first number of the "Almanac" was issued in the year 1853, and stereoscopic photography was at the height of its popularity; it is interesting to note that the editor states stereoscopic pictures should not be vignettised, but be sharp up to the edges, and mounted at 2½ ins. distance between corresponding points of the pair, and upon black or stone-coloured card.

Black cards for mounting do not seem to have caught on, and if workers knew how very effective they were I am sure they would be used. They have been strongly advocated quite recently by Mr. H. Underhill, of Oxford. In the advertisement pages of the 1862 volume will be found a picture and description of Hare's portable stereo camera, which weighed 12 lbs., and measured 8½ in. by 6 in. by 5½ in. From that year onwards the subject of stereo-photography—in some form or other—has rarely, if ever, been missing from the pages of that annual.

What is the present position of stereoscopic photography? Making generally, it is in a better position now than it has been for a quarter of a century. The manufacturers are catering for the stereo workers in every possible way, and there is really a dealer's catalogue but what has something in the stereoscopic line. It is not coming to the front in leaps and bounds, as many thought it would, but in a slow and steady manner. One little drawback to a beginner is, I think, the light confusion which exists in the matter of sizes. Roughly speaking, there are three: The real stereo size, 6½ by 3½, double size, 6½ by 4½, and the half-plate adapted for stereo work. After many years' continuous working with one or other of the sizes, I unhesitatingly give my verdict in favour of the "double size" (6½ by 4½). The majority of cameras on the market do not give pictures large enough for judicious trimming. I must, however, I strongly advocate the "double quarter" size. I do not wish to insinuate that good work cannot be done with the narrower plates, for I have seen and done excellent work on them; but they need—especially if it be a hand camera—a good worker to manipulate them, and, what is most

important, a good view-finder. This, however, is not intended to be a technical article, but a general survey, so I must proceed.

Stereoscopic postcards are on the market, and are selling well, and stereoscopic slides in half-tone may be had for about one penny each, and sometimes even less. The screen effect, however, is very irritating to the eyes, and I am now carrying out some experiments with a view to obviating the defect.

There is a lot yet to be done in the stereoscopic line. Old methods which have not been a real success might be revived and improved upon. At the present time, for example, there promises to be a revival of the old method of two-colour stereoscopic effect obtained by printing the two elements of the picture in complimentary colours on the same piece of paper or card, and viewing with similarly-coloured spectacles, so that each eye only sees its appropriate element of the stereogram. Hundreds of specimens made abroad have recently been put on the English market, and Messrs. Boots, of Fleet Lane, have sent us some of their productions, which they call bi-photo prints on cards about 4 in. square.

The desirability of stereo projection would naturally occur to the very earliest worker, and De la Blanchère, in 1853, seems to have been the first to attempt this, his idea being to project one picture through blue glass and the other through yellow, and provide the spectator with a pair of eyeglasses also provided with the same coloured glasses, that for the right eye being of the same colour as the glass through which the right-handed picture was shown, and the left eyeglass corresponding to the left-hand picture, thus apportioning each picture to the correct eye. The positives were of the ordinary type, and not themselves coloured, and the yellow and blue lights mixed gave white. The same idea was utilised by D'Almeida in 1858 only with green and red glasses, and later by Molteni, Schobbens, and Freshwater.

Anderton used polarised light, and each spectator was provided with prism eyeglasses, the screen being in this case covered with silver foil to obviate loss of light. Stroh utilised the phenomenon of persistence of vision, the pictures being alternately and rapidly thrown on the screen and eclipsed, an idea that has also been suggested for cinematograph work. Up to the present, however, there is no satisfactory method of stereo projection.

The last stereoscopic competition, held by the paper I have the honour of editing, opened the eyes of some of our critics, who, at the initiation of the competition, forecasted a failure, and said we were whipping a dead dog. The results were extremely satisfactory, the competitors running into many hundreds. The results afforded a welcome assurance that the revival of interest in this branch of photography, predicted a few years ago as follows by a former editor, Mr. E. J. Wall, may be regarded as fairly established:—

"It is undoubtedly the most perfect of every branch of photography, giving as it does an appearance of relief and solidity to the objects which is extremely realistic. It has for many years fallen into disuse, and only lately has there been a revival, and that entirely among amateurs. . . . Stereoscopic photography will, I believe, gain steadily in favour, and it ought to; for, as I have said before, the results obtained are unapproached by any other process, and if the main principles are grasped, and all the operations systematically carried out, it is not a difficult department of artistic photography."

In conclusion, let me say that in stereoscopic work it will be found that far greater power of making pretty and interesting pictures out of commonplace material exists than when using an ordinary monocular camera; and whilst the ordinary rules of composition apply it must not be forgotten that the real beauty of a stereoscopic transparency or print lies in its technical excellence and in its semblance of relief, and everything which goes to increase this is, generally speaking, an advantage. A hedgerow, bush, tree, or an uninteresting row of posts

or palings in the near foreground should be utilised, for by so doing the distant planes are thrown back and relief is much enhanced. Distant views without any near object should never be attempted, as, unless the two lenses are very widely separated, the subjects are wanting in relief, and appear uninteresting. I find that a prominent object within 15 ft. to 20 ft. of the camera gives, with ordinary lens separation, the best results. Flowers, statuary, studies of hoar-frost, and other

objects in relief make the best subjects. Fuzzy or so-called naturalistic—Salonic, if you like—pictures will not do for the stereoscope; we do not see such things in Nature. What is wanted is good, clean, honest, and pure photography. Will not some of our so-called leaders in the world of pictorial photography take up the stereoscope?

P. R. SALMON, F.R.P.S.,
Editor of the "Photographic News."

Orthochromatic Prolegomena.

HISTORY repeats itself. Twenty-five or thirty years ago photographers were regarding with the utmost reluctance the advent of the gelatine plate, clinging to the wet plate with one hand and reaching out in a tentative, half-hearted manner towards the dry plate with the other. A similar state of affairs has been repeated in the history of the orthochromatic plate. For at least fifteen years the colour-sensitive plate has been knocking at the photographer's door in almost its present stage of efficiency. Its acceptance has been even more half-hearted and protracted than that of the gelatine plate.

Two noteworthy instances illustrating the misuse of orthochromatic plates recently came under my notice. In one a tourist going abroad bought a supply of orthochromatic plates, and had his hand camera fitted with a filter; the majority of his exposures were made with the filter in position, and were of the usual "snapshot" character. It is hardly necessary to say that the resulting negatives were scarcely the "things of beauty and joys for ever" he intended them to be, and he rightly says that he gets on much better with the ordinary plate. In the other case a tourist took with him orthochromatic plates but no filter, and complains that he can see no advantage

Fig. 1.—View taken without a filter.

Within the last two years or so manufacturers and dealers have conspired to force orthochromatic plates and spectrum filters upon an apparently unwilling photographic public, and now on all sides orthochromatic plates and filters are used and misused with a generosity that contrasts strongly with the years of neglect they have suffered.

In many instances no effort seems to be made by the users of orthochromatic plates and filters to understand the principles that govern their application; it seems to be sufficient for most that they have light filters and orthochromatic plates, and are in a position to say that such and such a view was taken by their aid.

in them over the ordinary plate. A very little study of what for them, was quite a new departure in photography, would have obviated the subsequent disappointment, and have enabled them to realise the superior translation given by the orthochromatic plate.

At the risk of being elementary, and restating much that has been already many times and better said, I propose a review for the benefit of the uninitiated in orthochromatic photography the main points in its application to outdoor work, and I may, perhaps, be allowed to hazard the hope that the summary of orthochromatic procedure will not be inappropriate to the Jubilee Number of the BRITISH JOURNAL OF PHOTOGRAPHY.

PHY, a paper that in itself is a history of progressive photography.

It is a matter of common knowledge, even among beginners in photography, that some colours photograph "badly." Blue produces too light, while, on the other hand, yellows and reds are much too dark. The explanation of the difficulty lies in the fact that silver salts, as ordinarily used, are far more sensitive to the violet and blue region of the spectrum than they are to the yellow and red. As a consequence, blue becomes fully exposed before the yellows and reds of a subject have commenced to have any action on the plate, owing to its low sensitiveness to these colours. It must not be imagined, however, that silver bromide, of which gelatine dry-plates mainly consist, is insensitive physically to the yellow and red of the spectrum; a prolonged exposure would result in these colours impressing the plate to a considerable extent; but the exposures necessary to do so belong more to the domain of experimental photography than to the everyday work of the photographer.

Photographic physicists, quite early in the history of photography, found that it was possible to considerably modify the sensitiveness of the silver salts towards the different parts of the spectrum, by adding various substances to the sensitive silver salts; and Ives, in 1879, showed how collodio-bromide plates might be made colour-sensitive by treating them with a solution of chlorophyll. A few years later H. W. Vogel considerably advanced colour-sensitive photography, if, indeed, he did not lay the foundation of orthochromatic photography, as we of the present day know it.

It was readily seen that in spite of the advanced sensitiveness to the yellow and red rays conferred on the silver salts by dyeing the films or emulsion with eosine, etc., the general sensitiveness of the plate to the violet and blue was still far in advance of its sensitiveness to the less refrangible rays, so the source was had to checking the activity of the blue rays by interposing between the object and the plate a yellow screen, which filtered out some portion of the too active blue rays, while the yellow and red were allowed to pass with their energy undiminished. Orthochromatic photography, then, consists of dyeing the ordinary silver salts to increase their sensitiveness to the yellows and reds; but as this alone is not sufficient to secure correct visual interpretation, owing to the relatively greater sensitiveness of the plate to the blue, a portion of this colour is filtered out by the use of a spectrum filter.

Some few workers contend that by using an undyed plate with a yellow filter similar results are obtained as when using an orthochromatic plate. It is true that the yellow filter would depress the activity of the blue rays, and so a truer result would be had, but the exposure with an ordinary plate would be enormously protracted, in addition to which the sensitiveness of the ordinary plate to such yellow and red rays as passed through the filter would be infinitely less than in the case of the orthochromatic plate specially sensitised for these rays.

The beginner in orthochromatic photography, who elected to

make a comparative test in the field between an orthochromatic plate without the filter and an ordinary plate, would probably be much disappointed. If the test took place on an average subject in a good summer light, probably no difference would be observable between the two negatives; the blue sensitiveness of each plate is so great that the colour translation would be about equal. But if the yellow filter is used with the orthochromatic plate a very marked difference is at once seen; the blue of the sky is reduced in activity, so that in the negative the white clouds stand out against a dark background. The extreme distance is very much better rendered in the negative taken through the filter, for, as it is principally composed of blue rays, it receives much less exposure with the filter than without. In point of fact, unless the filter is used in conjunction with the orthochromatic plate, there is not much reason for employing the orthochromatic plate in average landscape work under ordinary conditions.

On the other hand—and this is a point to be insisted on—there is no disadvantage in always using orthochromatic plates.

Under certain conditions, for instance, when working late in the evening or on dull days, they do give better results without a filter than the ordinary plate; but the main reason for constantly employing them is that they are always available for use with a filter should it be desirable to use one. Looking back through my exposure books of the last fifteen years, the time during which I have employed orthochromatic plates and filters, I find the proportion of exposures with a filter shows a gradual increase, until now about seventy-five per cent. of them are made with the filter.

To enable the beginner to fully realise the importance of using a carefully-selected filter, I would direct his attention to the comparative test illustrated in Figs. 1 and 2. The subject is a forest glade of birch trees, taken towards the end of October, at four o'clock in the afternoon. The colouring was singularly vivid, the birch trees being a brilliant yellow,

GEORGE T. HARRIS, F.R.P.S.,
One of our foremost technical photographers.

backed by a bright blue sky, which was broken up with white clouds and dark patches of storm-drift. In the foreground were masses of dead brown bracken, and the shadows from the sun, only a few degrees above the horizon, stretched right across the glade. Fig. 1 was taken on a colour-sensitive plate without a filter, Fig. 2 being taken on a colour-sensitive plate with a filter, which increased the normal exposure three times.

It will be noticed that in the one taken without the filter the sky and clouds are completely lost, and that there is a roundness and suggestion of colour in the birch trees, the bright yellow being rendered many degrees too low for visual intensity in that taken without a filter. The one, in fact, is a mere photograph; the other brings back to me, who saw the original scene, instantly all its vivid colour and breadth of lighting. Quite early in my use of orthochromatic plates I noticed that months afterwards prints from those negatives taken with a filter recalled most satisfactorily the original scene, and this because the visual translation was truer and more in accordance with what the eye saw.

The tyro in orthochromatic work may think that any filter, so long as it is yellow, will give good results. This, however, is scarcely so; many of the yellow glass filters on the market would never give highly satisfactory results, as they remove so little of the blue. To be useful, the colour must be a bright lemon yellow, a colour rarely seen in glass, which is usually brownish yellow. The filter used with the illustrations here given was an ammonium picrate, similar to the one originally described by me in the *BRITISH JOURNAL Almanac* for 1893, and I think it would be difficult to beat it for all-round landscape work.

Much has been said about adjusting the filter to the colour-sensitiveness of the plate, and, of course, this is a necessity in such exact work as three-colour printing necessitates; but with landscape work less exactitude is permissible, and so long as the filter is of such colour and density that the activity of the blue rays is sufficiently checked, the work will be satisfactory enough for general requirements. Let the beginner be advised against using in his early work one of the filters of amber-coloured glass not infrequently sold for landscape

white clouds or a distance composed largely of blue atmosphere a filter will always be desirable. Again, when photographing on dull days, the greens of a landscape will be improved very much by using a filter. Late in the evening, when the proportion of blue rays has considerably diminished, the filter is less necessary, and I have frequently noticed the superior usefulness of the orthochromatic plate on evenings in the late autumn when towards sunset the atmosphere becomes suffused with yellow light. Used on such occasions without a filter the orthochromatic plate scores heavily over the ordinary. It must be remembered that in dealing with Nature there will always be a large amount of blue in the landscape, and unless this is modified by a filter the best results will not be obtained. It is worthy of note that there is less tendency to halation when using a filter, a fact not difficult to understand.

I know for a fact that many have been prevented from using orthochromatic plates by getting an impression that they must be developed in total darkness. Such a proceeding is quite unnecessary; all that is required is a good safe light and plenty of it. My own light is a paraffin lamp, with a single thick

Fig. 2 —View taken with Filter.

work. These increase exposure from eight to ten or twelve times, and nearly always give over-correction from the blue being too completely removed, as a consequence of which the green of trees and grass appears many shades too light in a print. Deep filters occasionally are of extreme usefulness, but their application requires great care if a false result is to be escaped.

Under-exposure must be carefully avoided when using a filter if a satisfactory translation is to be obtained. It is quite astonishing what an amount of apparent over-exposure an orthochromatic plate with a filter will stand. The plate during development may seem wholly devoid of unconverted bromide, and yet the fixed negative prove to be full of fine gradation. If the negative has to be forced during development, from slight under-exposure, the result will be untrue as regards its translation of the visual intensities.

The beginner's principal difficulty will be that of knowing when to use the filter. When a large amount of blue enters into the colour of the landscape, either as blue sky with

ness of good ruby glass and another of canary medium. The plate is flooded with the developer and the tray covered, being looked at occasionally until development is completed. There need be no fear of fog even with the most sensitive orthochromatic plates if care is taken not to unduly expose them to the dark-room light.

It may not be out of place to make some reference to orthochromatic plates themselves. All plates of this kind issued commercially are certainly coated with orthochromatic emulsion, as "dipped" plates would not keep sufficiently well for commercial purposes. At the same time it is questionable whether dipped plates do not give the best orthochromatic effect; they certainly impress me as being more sensitive to the lower part of the spectrum than when the emulsion is prepared orthochromatically. For flower studies, indoors, I have frequently employed ordinary plates, dipping them just before use, and exposing in a damp condition. The results certainly left nothing to be desired from an orthochromatic point of view.

Development of orthochromatic plates need present no diffi-

culty to the beginner. Any developer that suits the plate can be used, except hydrokinone, which is unsuitable, as it gives too steep a gradation to allow of the best translation of the original tones. Density is gained very quickly with most colour-sensitive plates, and some care is necessary to avoid obtaining a negative too hard for the best representation of the original tones.

Space does not allow me to traverse the whole ground of the applications of filters and orthochromatic plates in landscape practice; much might be written of the great usefulness of deep-coloured filters in mountain regions, where for days together the worker is confronted by provoking haze. The

experienced worker is not often caught without a filter or series of filters.

I make no pretence in these notes on elementary orthochromatic work, of suggesting that more artistic work can be done by the aid of filters and colour-sensitive plates than could be accomplished with ordinary plates. I should say, judging from a good deal of the artistic work shown, that the ordinary plate is eminently suited to its production; what I have no hesitation in saying is, that if anyone desires a transcript of some scene which pleases him, and desires to recall it as he saw it, then orthochromatic plates and filters will help him as nothing else will.

G. T. HARRIS, F.R.P.S.

Half a Century of Ceramic Photography.

THE above title may surprise some of the young photographers who have never seen or heard of a genuine enamel. I say genuine to distinguish them from collodion and other glazed photographs or imitations, which are often misnamed enamel photographs. I am much surprised that the genuine article is not more popular, seeing that processes published are not difficult or expensive; the plates are the most costly part after the furnace. About fifty years ago Count Lafon d'Camersac

process, which from an original negative gives extreme fineness of grain, even when enlarged.

During the fifty years many experimenters entered the field with varying success, but from some unexplained cause they did not persevere; I daresay, believing that the difficulties were too great. I remember on more than one occasion would-be enamellers sending for a couple of plates. I could tell some strange and funny stories, but will reserve them for another occasion. One idea seems to have taken hold, that the difficulty lies in the firing. I never found the smallest difficulty with a

[S. J. Beckett.

A. L. HENDERSON,

A veteran photographer, experimentalist,
and traveller.

astonished the world by producing the first good vitrified photographs. I have an example done by that gentleman which would be difficult to beat. His method, as far as I know, has never been published. Suffice to say I believe it was a dusting-on process; the one he produced for me was from a transparency. As a rule, the dusting process gives great latitude in colour, but necessitates a good deal of working-up. Then there is the so-called substitution (a misnomer)

properly-prepared image; it is almost impossible to send it up the chimney (a trade expression). My initiation into this art is now a story of the past. It came about by the late J. T. Taylor challenging me to produce enamels. My process has been published and demonstrated so many times that a recapitulation is unnecessary. I am not aware of a more interesting or lucrative branch than enamelling. It will "catch on" some day.

A. L. HENDERSON.

Then and Now.

IN contrasting the practice of photography as it was, and as it is, a slight sketch of the trials and troubles of a photographer of the old days may not be out of place as a contribution to this issue of the *BRITISH JOURNAL OF PHOTOGRAPHY*.

Then, indicating the sixties, a day's satisfactory outing with the camera was an undertaking not to be lightly entered upon, in marvellous contrast with that of the present day. For the information of those not conversant with wet collodion work in the field, and to emphasise the advantages of the modern methods of working compared with it, I will give a *résumé* of what was needful to obtain a negative in those days. To ensure having all things necessary it was customary to make a list of everything required and attach it permanently to some convenient part of the outfit. By going over this list item by item when packing up trouble was avoided. I will not, however, occupy space by enumerating the various articles, but there were very many things the modern dry-plate photographer has fortunately no occasion to use, but which might have caused great inconvenience if forgotten, even to the stoppage of a day's work. *Imprimis*, there was the tent or portable dark room, a heavy, roomy affair fitted with bottles, bath, etc., a complete photographic laboratory, as all the processes, from sensitising to developing the plate, was carried on in it. The silver bath, a most unstable and irritating solution, was always liable to get out of order at the most awkward times, then it had to be filtered and tested, and gave an unconscionable deal of trouble, having to be remedied on the spot. The plates, too, had to be most carefully handled—the least fingermark or dust causing defects in the negative. Six or eight plates were considered a fair day's work, but extra plates were generally taken. The collodion required special attention, being filtered back into a container, after coating each plate. The tent was constructed so that it formed a box sufficiently large to contain most of the appliances required, supplemented by another box with the chemicals, lenses, etc. As a precautionary measure, the camera was usually taken in a case by itself. Bucket and jugs were also necessary, the whole outfit weighing between one and two hundredweight. (I may say plates, 12 by 10 in size, were used.) Detachable wheels and handles that could be affixed to the box turned the whole thing into a sort of hand-cart on an emergency.

Arrived at our destination, the first thing was to find a spot sheltered as much as possible from sun and wind and near to a water supply, a very important condition, for without water

photography could not have been carried on. Providing the district was unknown, an excursion was made during the time the tent was being set up and generally prepared for working in. All being in readiness, the camera was focussed, the plate prepared, coated in the open and sensitised in the tent, drained and put into the dark slide, resting the corners on blotting paper to absorb any drainings. The plate once put in the slide, care had to be exercised to keep it in the same position until it was taken out to develop, or possibly some of the drainings might run back over the plate and cause defects. In developing, the plate was held in the hand, the developer swilled over it, and the surplus poured off the plate into a cup in which a few drops of nitrate of silver solution had been

introduced. This was to secure density, which was seldom sufficient without this so-called reintensifying. The plate was then freely washed with water and fixed with cyanide solution, washed again, and put into a rack to drain. A very few minutes sufficed for this part of the business, forming a marked contrast to the time occupied in treating a gelatine dry plate. Exposures were very long—counted by minutes instead of seconds—and a two-minutes' exposure might be extended over half an hour or more, caused by frequently capping the lens when the wind was troublesome or moving objects got in the field of view, and a wait had to be made until they had disappeared. When the day's work was over and everything repacked for travelling, the photographer himself required a wash and brush up, with the energetic application of pumice stone and cyanide to his hands, which in the course of the day had acquired a very disreputable appearance. Given a hot, windy day and a bad supply of water, a day's outing in the sixties could scarcely be called a pleasure. In

this year of grace, 1904, what a difference! no bother about tents, and developing plates always ready and will keep any time, no dirt and mess or anything to interfere with an enjoyable stroll—no wonder photographers have increased by the thousand and photographs by the million! But has the improvement in apparatus and material, etc., been matched by improvement in the resulting work? Lighting, composition, and exposure are the chief factors in a good picture, and now that the distractions of a troublesome process have been eliminated, all the attention can be given to the pictorial side, which, I think, should show a more marked improvement in general work than is perhaps to be found in it. Anyway, in this direction only is it possible to make any progress.

EDWARD DUNMORE.

EDWARD DUNMORE,
Formerly Hon. Sec. of The Photographic Club.

Orthochromatic Photography.

It is desirable upon occasions such as we are at present celebrating to pause and consider what advances have been made in a given period of time. More especially is this necessary for those who specialise, as it prevents retrogression, a failing in the photographic world which is far too common. From the first the photographer has been troubled with the fact that the luminosity and sensitiveness of colours are not in concord, and it was Crookes who suggested in 1858 that if a yellow screen were placed in front of the sensitive plate there would be a marked improvement obtained in the rendering of the colour luminosities; the writer by using an artifice of this nature has obtained correct colour rendering upon an ordinary plate of extreme rapidity, but the exposure was very long, and it will be seen that with the slow sensitive medium in use at that time Crookes' yellow screen would not receive much attention.

About 1873 the late H. W. Vogel, when photographing the spectrum upon various kinds of collodion emulsion, observed that upon some plates he had obtained, made by Stuart-Wortley, there was an additional light action obtained in the green, caused, as transpired later, by the action of aurine which had been used to stain the plate in order to prevent halation. Vogel followed up his discovery and ultimately announced to the world that by staining the emulsion with various dyes it is rendered sensitive to the brighter colours of the spectrum.

Many renowned experimentalists attacked this subject, and in 1875 Waterhouse discovered the value of eosin as a colour sensitiser, and in 1879 Ives published the method of orthochromatising collodion bromide emulsion by means of chlorophyll. In 1882-83 Tailfer and Clayton took out a patent for orthochromatising gelatine dry plates by means of eosin and erythrosin used in conjunction with an alkali, and plates prepared under this patent by B. J. Edwards and Co. were placed on the English market in 1884.

It was, and is still, necessary to use a yellow screen, or, as it is now called, a light filter, in order to subdue the action of the blue and violet rays of light and to stop the action of the ultra violet light; but for quite a long period these light filters were selected and used haphazard, except in the case of one or two careful workers, who devoted much time and skill to adjusting the light filter to the plate by means of the spectro-scope in order to obtain correct colour rendering, but it re-

mained for Sir W. Abney to give to the world an instrument which is known as the colour sensitometer, by means of which it is possible to rapidly and accurately adjust the absorption properties of a light filter to the colour sensitiveness of the plate, so as to obtain a true rendering of colour luminosity into monochrome.

To illustrate the advance that has been made in solving this problem of correct colour rendering, it is interesting to note that if an extra-rapid ordinary gelatino-bromide plate and a colour-sensitive plate of equal speed be selected, and have light filters adjusted to them so as to obtain in each case

correct colour rendering, the practical results obtained by these two plates, each used with its own light filter would be identical in colour rendering, but it would be found that the light filter used with the ordinary plate would increase the exposure about 7,000 times, whilst in the case of one of the latest brands of colour sensitive plates the adjusted light filter only increases the exposure about 10 times, so that though the photographs would be similar in character, that which had been taken upon the ordinary plate would require an exposure 700 times as long as one taken upon the colour sensitive plate.

Within the past year there has been introduced a colour sensitising dye known as Orthochrome T., which marks a step in advance, for, unlike most colour sensitisers, not only does it make a plate which has been bathed in its solution colour sensitive, but it also greatly increases the speed of the plate. The writer has found that by bathing an ordinary clean working plate ("Electric") of a speed of about 120

H and D in a weak solution of this dye, the speed of the plate is increased for daylight to about 250 H and D, whilst for yellowish, artificial light the speed reaches the maximum of between 500 and 600 H and D, and when a light filter is adjusted to this bathed plate in order to obtain correct colour rendering, it only increases the exposure about five to six times, so strong and even is the colour sensitiveness conferred upon the plate by means of this dye.

The goal of all experimentalists in this work is to obtain a plate which in itself, and without any screening, gives correct colour rendering and at the same time maintains and increases the present high sensitiveness obtained in modern dry plates.

ARTHUR PAYNE, F.C.S.,

Has devoted special attention to the study of orthochromatic photography.

Collodio-Bromide: Forty Years' Experience

IT is now just forty years since this beautiful process was first introduced in the pages of this JOURNAL by Messrs. Bolton and Sayce. My experience dates from the time of its introduction, and I have worked at it from the commencement. It seems a very long time to look back. I first used it for negative work and transparencies for window decorations, and also for stereoscopic slides. For the latter it is unsurpassed on account of the varied rich tones obtained by it. In the early seventies I was making enlarged negatives up to 24 by 18 in., using it in the wet state. As originally published, the formula was very crude, and also the way of compounding. This was of the unwashed order. Matters have considerably changed since then. M. Carey Lea and others elaborated it.

In or about the year 1880 I devised a plan of reproducing a negative from a negative without having to make a positive. I made the exposure either by contact or in the camera, and the image when developed was a positive; the plate was then well washed, and flooded with a strong solution of iodine in alcohol, and allowed to act until the image was perfectly invisible, again well washed, and then flooded again with the alkaline developer. The positive image again made its appearance, and after a short time this positive image gradually disappeared, a negative image taking its place; development was pushed until the requisite density was obtained, and fixed with cyanide as usual. If the iodine was not allowed to act long enough, the final result was partly negative and positive—a regular mix-up. The iodine fumes were too overpowering to admit of its being used, so I gave it up. I published it at the time.

Colonel Stuart-Wortley in the seventies or early eighties introduced into the emulsion nitrate of uranium, for what purpose I could never understand. He said it was to increase the sensitiveness, but I found it quite the reverse. W. J. Stillman at the time attacked him on the same point as to its uselessness, and said it was no more use in the emulsion than ground bones and sand, which led to some bitter correspondence in the journals. Mr. Leon Warnerke gave some valuable information as to the use of various bromides. The

late Professor Dawson and Henry Cooper were earnest workers on the subject, and lent valuable aid. I remember when the Liverpool Dry Plate Company issued plates under Mr. Peter Mawdsley I experimented with some of the first issued and obtained good results. They were on the market for a long time. This was before the days of washed emulsion. At this time I was also making emulsion for my own use. When the washed emulsion came in, matters were considerably altered. I think it was Mr. W. B. Bolton who introduced washing the emulsion in bulk, at the time we were experimenting together.

Mr. Peter Mawdsley has shifted from Liverpool to Clapham Junction, and issued the washed emulsion. About the same time Henry Cooper's emulsion was put on the market by Messrs. Horne & Thorne, of Newgate St., London.

With the washed emulsion of my own make, I soon recognised its adaptability for lantern slides, and am still using the same system very largely at the present day.

The greatest difficulty that has had to be contended with was a suitable pyroxyline. I seemed next to impossible to make two samples exactly alike in quality. I was determined that it should not master me. I spent an enormous amount of time (years) and a great deal of money. I obtained samples of cotton from all parts of the globe, and it was not until about two years ago that my efforts were crowned with success. I found most of the formulæ published in books were copied from one another. I have not the slightest difficulty now in making any number of batches of pyroxyline exactly alike. The class of pyroxyline that is required is a sample that will make

a fluid collodion and that will adhere to the glass plate, and have a strong organic reaction that will combine with the silver. These qualities I can now obtain at will, and without the slightest difficulty, if I keep within certain prescribed lines. One thing I forgot to mention was that artists' flatted canvas coated with it develops with a beautiful sepia tone, and combines with the oil colour on the canvas. As my work has covered forty out of fifty years, and the process was published in these pages in 1864, I do not think it will be out of place in the year of THE BRITISH JOURNAL OF PHOTOGRAPHY Jubilee Number.

WILLIAM BROOKES,
An authority on collodio-bromide emulsion.

WILLIAM BROOKES.

Photomicrography of Rock Sections.

THIS is one of the most interesting applications of the microscope, and one to which, so far as can be learned, not much attention has been paid in photographic literature. The sections of rocks are so varied in their character that to very few of them can the same mode of lighting and illumination be applied. It may be stated generally that granite and its three components, quartz, felspar, and mica, form the basis of all rocks. Many other chemical substances assist in giving character and variation in a greater or less degree; but the three components of granite are the ruling features in the whole of them. The chief use of the photography of rock sections may be said to be the production of lantern slides for teaching purposes. A good negative when reproduced in this way most materially assists in the illustration of a geological lecture. In fact, to a class, or in a lecture of a more popular form, such assistance has now become indispensable. In the production of negatives from rock sections it is, with few exceptions, only necessary to use low magnifications. Only the other day a section of rock was asked to be photographed, having an elliptical shape, the major axis of which was over an inch in diameter. As no micro low-power objective covers more than five-eighths of an inch, recourse was had to a Zeiss Unar of $4\frac{1}{2}$ in. focus stopped down to f 11, and this gave a very fine sharp negative. The microscope portion of the camera was removed, and a supplementary stage on an improvised suitable rigid easel was used to carry the section. Another method used for a different material may be mentioned, with which very fine results were obtained. If, for instance, one is required to take a negative of some grains of sand to show the character of any particular variety, the procedure may be as follows:—Take an ordinary glass slip 3 in. by 1 in., give it a few strokes with virgin wax (white wax), hold the slip over a Bunsen burner, or spirit lamp, until the wax melts, which may then be spread with the finger, then sprinkle the sand over the melted wax, to which it adheres. The wax will cool at once. The slide is placed on the microscope stage, with a piece of dead black paper behind it, and after focussing by means of a gas jet or lamp, the illumination is made by burning a few inches of magnesium ribbon held behind the objective, and gently waved about. The objective used in such a case may be a 70mm. by Zeiss, and a camera extension of about 18 in.

A great number of rock sections, to enable them to be photographed well, require the use of polarised light to differentiate their structure, and many also as well the use of a depolarising selenite. Some of them show best for photographic purposes when examined with the crossed nicols only without the selenite, while others again absolutely require the selenite to reveal the structure properly. Agate and the various forms of felspar may be mentioned as rendering this illumination necessary; while, on the other hand, the selenite may not be used with many of the forms of granite, as the crystals of granite itself show so much colour that only the crossed nicols are required. No absolute rule can be laid down as to the mode of procedure either as regards the illumination required or the use of polarised light. Every one must just exercise his own discretion and skill in such matters. When a considerable experience with the microscope is possessed by the operator no difficulty will be found in judging what is the best mode of operating to obtain the best results. One thing is essential above all others for success in this work, and this undoubtedly is that the sections must be thin. There is not much difficulty nowadays in getting thin sections compared to those which could be obtained some years ago. Another point is the objectives used must be corrected for the chemical focus. It will not do to attempt this work with any ordinary micro-objectives. Even with the low powers which are, except in certain cases, only required, the results obtained must be sharp and clear. They have to be so, as, when projected by the lantern, defects become so very apparent. The illumination used by the writer is invariably magnesium ribbon. The image is first focussed by an ordinary lamp, which is then removed, and a small piece of brass tube, about three-sixteenths of an inch in diameter, having been previously fixed in a shutter, and placed exactly in line with the optical axis of the microscope, the magnesium ribbon is pushed through the tube and ignited. If more than two or three inches is required the ribbon may be pushed through the tube with the left hand while burning until as much is required as is necessary. In this way the exposures are so short that little time is lost. No instructions, however, will render experience useless. It is only by long practice that any one can hope to succeed in any department of photography.

W. FORGAN.

Dr. Miethe's Methods of Colour Photography.

FOR several years past Dr. Miethe and his staff of the photo-chemical department of the Charlottenburg Technical School have busied themselves with details of the triple or synthetic process of colour photography. While they have not made any one radical departure from existing methods, they have improved the process at a number of points that colour photography as a craft or an amusement is brought much more nearly within the skill of the average individual. Fortunately, Dr. Miethe is not a chemist or a physicist only. He is a photographer as well, and each advance, made in the course of scientific research, has had to withstand the test of practical photography. When I was in Charlottenburg, two years ago,

Dr. Miethe showed me a series of about fifty three-colour exposures made by himself on a holiday trip to test the sensitisers they were then using.

Although the Charlottenburg work has been much talked about in the photographic press, there has been very little technical description of it, but Dr. Miethe has now written a small work on the subject* from which we are able to draw up the following review of what has been done. We can do no more than pick out some salient points. The volume itself should be read by those who wish to possess the most explicit working instructions in tri-colour work which have yet been published.

* Dreifarbenphotographie nach der Natur, by Prof. Dr. A. Miethe, Hon. F.R.P.S. (Halle: Knapp. M.2.50).

The language, though that of a scientific man, is free from learned phraseology, and the frontispiece, a "process" reproduction of one of Dr. Miethe's landscape exposures, is an incentive to colour photography more powerful than words. The subject is "Early Morning in the Dolomites."

Coming now to Dr. Miethe's text:—

The sensitising formula first used for the preparation of a panchromatic plate contained the three dyes, glycin red, chinolin red, and cyanin, a mixture which gave plates of extensive colour sensitiveness and good keeping properties. The dyes, however, could not be incorporated in the emulsion, and in 1901 and 1902 an examination of dyes was commenced which resulted in the now well-known "ethyl red," the first single dye to sensitise the plate to the whole visible spectrum. "Ethyl red" is one of many derivatives of cyanin: which dyes had been previously examined by others without their remarkable properties being noticed, probably because they were not obtained chemically pure and were used in too great concentration. Ethyl red—or ethyl iodo-chinolin chinaldin iso-cyanin, to give it its full name—sensitises into the orange, but its action falls off sharply at the extreme red of the spectrum so that a properly-chosen dark-room filter can be used for the preparation and development of the plates, a point wherein ethyl red differs from a later derivative of cyanin, orthochrome, which sensitises further into the red.

Ethyl-red plates, either with the dye in the emulsion or applied by bathing, keep in good condition for many months. In preparing the bath for the latter method 1 gramme of the dye (as made by Böhringer, Mannheim) is dissolved in 500 ccs. of hot alcohol and the solution filtered. This alcoholic solution with a little ammonia added keeps in the dark for a very long time. It is diluted for use with 100 times its volume of distilled water—i.e., to the concentration of 1:50,000, and 3 to 5 ccs. of strong ammonia added per litre. This bath gives fog if used fresh, but after standing a day or two in the dark loses this defect. The plates are bathed for two minutes and washed for three, this operation being performed in light, filtered as described below, or in total darkness. The plates are then dried as rapidly as possible.

Drying has an important bearing on the resultant plates. Plates slowly dried are less colour-sensitive, do not keep so well, and tend to foggy and flatness. Protracted drying even causes other defects, such as streaks and irregular markings.

For drying plates on a moderate scale a drying cupboard fitted with a 1/16 horse-power electric ventilator is used. The ventilator, which costs from 50s. to 60s. from the Siemens-Schuckert factory, is fixed underneath the cupboard and draws a current of air down through light-trapped canals in the top of the cupboard, the plate rack being covered with a kind of "baffle plate" to cause a uniform stream of air over the plates.

A larger installation has been constructed in which plates can be dried within an hour and a half. For this the air is first cooled by passing through a copper tube externally cooled with water. It is thus reduced to a constant state of moisture, whereas if warmed without this preliminary cooling its drying properties would not always be the same at one given temperature. The dried air is then warmed by passing through gas-heated copper tubes. Its temperature at the entrance to the drying chamber is adjusted to 32-33 deg. C., which is allowed to rise to 35 deg. C. when the plates have been there a quarter of an hour.

Ethyl-red bathed plates have preserved their properties during fifteen months' storage in a damp place, developing at the end of that time free from spots or fog round the edges.

In the matter of a camera, the balance of advantage rests with a simple one-lens apparatus, fitted with an attachment whereby plate and filter drop together by the action of gravity.

The change from red to green and blue filter is thus made in the fraction of a second, and the whole kit weighs only 4 lbs. The total time for the three exposures with a lens at f 19 runs to about 2 seconds—1 second for the red and half a second for the green and blue. As such exposures cannot be accurately given by hand, and as accuracy is a very important factor in the case, a diaphragm shutter is used. One made by Görgen, of Munich, has proved reliable, but doubtless other similar ones can be found.

Preliminary to any regular work we must fix, first, the relative exposures required by the three filters, and secondly the absolute exposure for certain conditions of light and subject. The former is done by the usual method of photographing a white object, varying the exposures until the three negatives are alike. But certain precautions are necessary. A bright day, but one with plenty of clouds in the sky, should be chosen, and the test is best made in a light room with walls of neutral grey, these conditions ensuring an illumination which does not

alter in intensity or colour during the test. A white plaster bust against a grey background is a suitable object. A test is made and the plate developed with 1:30 rodinal or edinol. If all three negatives do not present a completely similar appearance, especially in the half-tones, further sets of exposures are made until they do.

The absolute time of exposure is determined out of doors best in the absence of sunshine and with some openly-situated object as test object. The Wynne meter has proved a reliable basis for determining exposures. A series of preliminary tests are made to ascertain the relation between a certain time of darkening with the Wynne and the exposure required for the ethyl-red plate (blue filter) under certain conditions. A table can be drawn up from these data.

In development a soft clear negative is aimed at, and in arresting the process one goes by the appearance of the red-

MR. GEORGE E. BROWN, F.I.C., F.C.S.,
Associate Editor of "The Photogram."

sensation exposure, disregarding the blue exposure which frequently appears hopelessly under-exposed.

Ordinary ruby light, as used in dark rooms, can be employed with ethyl-red plates, but the worker is strongly advised to provide a safe light by soaking two unexposed, fixed, and washed gelatine plates, one in

Tartrazin (Merck) 20 grms : water, 500 ccs.

The other in

Methylviolet, 5 grms : water, 500 ccs.

The plates are immersed for five minutes, rinsed for ten seconds in clear water, and set aside in an upright position to dry. They are then varnished and bound film to film.

The additive or direct method of building up the three colour records is greatly preferable to the subtractive method in point of being scientifically adjustable, although the latter is of commercially the more importance. The kromskop, if provided with spectroscopically adjusted filters of stained films on glass (not the body coloured glasses used by Ives) is able to give a rigidly accurate and automatic reproduction of the colours of the original.

For projection purposes, a new form of lantern is advanced as an improvement on that of Ives', which permits only a very moderate magnification of the transparency. For the new apparatus the transparency is printed in one piece from the triple negative. Behind each section of the transparency is a small rectangular plano-convex condenser with its own limelight or

Nernst lamp. A projection lens is before each transparency, and the three images are brought into coincidence on the screen by depressing the upper lens and raising the lower one—in each case parallel to the optical axis of the projecting system. The colour filters are introduced just behind the projecting lenses.

A large projection apparatus has been constructed on this same system by the optical firm of C. P. Goerz, but in it the three transparencies are cut and can be adjusted beforehand by means of a special piece of apparatus instead of in the lantern at the time of exhibition. The apparatus consists of three projection systems, each with arc light, heat-filter, light-filter, and projection lens. This instrument permits of projection on the largest scale with perfect registration, and it has been used for the illustration of lectures in the Urania Theatre, Berlin.*

Coming now to the preparation of transparencies or prints by the subtractive method, the powder or dusting-on process has been found very suitable for pictures of large size, although some considerable practice is needed to work it. The gum process is much simpler—in fact, tri-colour gum is no more difficult than the ordinary multiple gum practised by the "pictorial" photographers.

GEORGE E. BROWN, F.I.C.

* The theatre here mentioned by Dr. Miethe is a kind of modern and photographical equivalent of the old Polytechnic in the days when it existed for popular entertainment. On the occasions when I have visited it the lantern illustrations were to the size of about 15 to 20 ft.—G. E. B.

On Stereoscopic Experiments in the Eighteenth Century.

WHEN Ch. Wheatstone* gave his splendid discovery to the scientific world he had tried his utmost to ascertain whether any philosopher had been in this field of investigation before. He came to the conclusion that the only instance of binocular vision of relief which he had found recorded previous to his own investigations was R. Smith's experiment with a pair of compasses. We will cite R. Smith's own words:—

Having opened the points of a pair of compasses somewhat wider than the interval of your eyes, with your arm extended hold the head or joint in the ball of your hand, with the points outward and equidistant from your eyes, and somewhat higher than the joint. Then, fixing your eyes upon any remote object lying in the line that bisects the interval of the points, you will first perceive two pair of compasses (each leg being doubled) with their inner legs crossing each other, not unlike the old shape of the letter W. But by compressing the legs with your hand the two inner points will come nearer to each other, and when they unite (having stopped the compression) the two inner legs will also entirely coincide and bisect the angle under the outward ones, and will appear more vivid, thicker, and longer than they do, so as to reach from your hand to the remotest object in view, even in the horizon itself, if the points be exactly coincident. This appearance will continue the same wheresoever you direct your eyes to any other collateral objects; nor will it vanish by variously inclining the plane of the legs to the horizon, or by any other means than by looking directly at them. The like appearance will happen when two equal round slices of a cork, or any two equal surfaces, are stuck upon the points of the compasses.

In his Remarks (Vol. II., p. 526) R. Smith describes another manner of viewing the compasses (by internal squinting or by directing the axis of the right eye to the left hand of the compasses and the axis of the left eye to the right hand), and

expressly mentions that the united middle leg will decrease in apparent magnitude and approach towards the eyes, if the real legs are more and more opened.

These stereoscopic observations were known to Ch. Wheatstone, and referred to by him in 1838. At the time of his second lecture, 1852, he mentions another instance of R. Smith's observations (Vol. II., rem. 532), that of the observer's face viewed with both eyes in a concave mirror seeming larger, remoter, and more concave than in monocular vision.

R. Smith's first experiment with the compasses caused considerable attention, and it was well remembered even to a time when Ch. Wheatstone's theory was not published. A reference to it we see, for instance, in Gohler's "Physikalisches Wörterbuch" (article Geischt, Vol. IV., p. 1,474, Leipzig, 1828). After the discovery of stereoscopy both experiments with the compasses were treated by Sir David Brewster, and I very well remember a discussion on this subject I had last autumn with Mr. J. F. Cheshire.

Some time ago, having attentively read Ch. Wheatstone's ingenious papers, and having noticed his references to R. Smith's "System of Opticks," I turned to this book in order to acquaint myself more intimately than before with the ideas of this old author. I was much astonished to find that some other experiments of this kind are also published, which seem to have escaped as well Ch. Wheatstone as Sir D. Brewster's attention.

In looking through a binocular telescope—the tubes of which were carefully directed to a distant object—and directing his attention to the circular openings of the diaphragms of the eye-pieces, they appeared to R. Smith (Vol. II., p. 388) larger and remoter:—

These equal rings, by reason of the equal eye-glasses, appear equal and equally remote when seen separately by each eye, the other being shut; but when seen united by both eyes they appear much larger and remoter, too, and the objects seen through them do also

* Charles Wheatstone: "Contributions to the Physiology of Vision." "On some remarkable, and hitherto unobserved, Phenomena of Binocular Vision." I. (Read June 21, 1838) Phil. Trans. 1838, p. 371-394. - II. (Read January 15, 1852) Phil. Trans. 1852, p. 1-17.

† Robert Smith: "A Compleat System of Opticks." Cambridge 1738. 2 Vols.

appear larger, though circumscribed by the united rings in the same places as when seen separately.

A similar appearance by means of a pair of spectacles was described by him in his Remarks (Vol. II., rem. 696) as follows:—

The phenomenon of the enlarged circle of the visible area, explained in these articles, may also be seen very plainly in looking at distant objects through a pair of spectacles, removed from the eyes about as far as the length of the hold-fasts (made for fixing them to the temples), and held steady at that distance. The two innermost of the four apparent rings that hold the glasses will then appear united in one larger and more distant ring than the two outermost, which will be hardly visible unless the spectacles be farther removed.

But far the most striking stereoscopic experiment recorded by R. Smith seems to me to be the following, where the two objects to be united must be drawn on paper.

In altering the second experiment with the compasses, R. Smith employed two lighted candles instead of the compasses' legs, and observed a middle candle lying midway between the real ones, and appearing at the same time smaller. By separation of the real candles it was effected in the same way as the united leg of the compasses in the second experiment. In drawing Fig. 161 in order to explain this candle experiment, R. Smith discovered that a precisely similar effect of a vertical line might be obtained by drawing straight lines on a horizontal plane, or, to follow his own words (Vol. II., rem. 527):—

And, by the way, if the lines *afe bfd* be drawn upon a plane-board a foot or two long, and a pin be stuck upright at their intersection *f*, and the pupils of the eyes be placed near the edge of the

DR. MORITZ VON ROHR, DR. PHIL.,

Is the author of the classic "History of the Photographic Lens."

board at any small height above the points *d e*, while the pin is viewed steadily, the two lines *fa fb* will appear united and upright in the place or by the side of the pin. For in this case they cannot

appear in two different places, and therefore must appear in the common intersection of two planes passing through the lines of *a, bf* and the pupils of the eyes.

If any reader should like to repeat this old experiment, would suggest, in accordance with R. Smith's words, a vertical distance of 30cm. (1') from *f* to *de*; as a middle interocular distance *de* is about 63.5mm. (2½ in.), the convergence at *f* is much less than in R. Smith's figure. If we only draw the

R. Smith's Rough Sketch to the Stereoscopic Experiment.

lines *fa* and *fb*, omitting the parts *fe* and *fd*, we see a vertical line at *f* above the plane of the paper. After completing the lines *ea* and *db* we perceive a vertical line passing through the plane of the paper at *f*.

From the foregoing we see that R. Smith's experiments were three-fold:—

1. The stereoscopic combination of simple geometrical figures, with parallel or nearly parallel axes of the eyes (experiments with binocles, spectacles, and the compasses' legs holding equal surfaces on their points).

2. The stereoscopic combination.

- (a) Of two different real points, together with the perception of their united image, coinciding with a distant object (first compasses' experiment).

- (b) Of two movable points, together with the perception of the alteration in the apparent distance of the united image (second compasses' and the candle experiment).

3. The stereoscopic combination of two different pictures of a simple object (a vertical line on a horizontal plane).

The foregoing will hardly leave room to doubt the excellent faculty of observation exhibited by Dr. R. Smith. At the same time it shows how very difficult it was even for keen observers to develop the theory of the stereoscope. The very circumstance of R. Smith's having produced the first stereoscopic drawing exalts our admiration for Ch. Wheatstone's genius.

M. VON ROHR, Dr. phil.

NEXT week's number of the BRITISH JOURNAL OF PHOTOGRAPHY will contain the first instalment of the BRITISH JOURNAL ENCYCLOPÆDIA OF PHOTOGRAPHY. This compilation of photographic information will form a most reliable guide to all processes in photography, and will be continued week by week until complete. The "B.J." should, therefore, be filed for reference in future. The various subjects treated in the Encyclopædia will be dealt with in alphabetical order.

A Note on the Present Position of Pictorial Photography.

I WAS asked the other day, "Is pictorial photography bankrupt?" and my reply was "No; but the experimental stage is over; pictorial photography is just returning to its legitimate limitations, and the wild eccentricities of the 'would-be original' are becoming offensive to everybody."

As one who as judge has had the bulk of the best recent work passed before him, or seen other work not sent to be judged, it is to me obvious that the various cranks have had their day, and that the tide is flowing strongly back to pure naturalistic photography—the one method of expression by the camera which will weather all storms and last.

The "sharp" pictorial photograph has long been dead—the Vernon-Heath school, if I may so call it. Dead also is the dressed-up outdoor model of the Robinson school; dead is the "all-a-little-out-of-focus" school as advocated by Newton, and best exemplified by the late Mrs. Cameron, whose notable work still remains a landmark of this style. Of the newer experimentalists, the "pure pinhole" is dead, as is the gum bichromate process, though a few of its admirers still persist in what has always been at best an imperfect printing process as compared with the ordinary carbon process; and dearest of all is the "faked print" of the earlier photographer brought to its full sterile seed by the Hinton school. This coarse and unphotographic method was the outcome of the cry of mediocrity against the obvious limitations of the camera, and, curious to relate, their sterility of ideas and ineffectual selection have made them the ugliest, as well as the most pretentious work of the camera. At a recent exhibition, where I had the honour to judge with two artists, one a rising genius, there was but a single example of this pretentious work, and our general verdict was, "How positively ugly, how crude, how lacking in everything that pictorial work requires, and how false!" And yet some ten years ago this very photograph would have received awards all over the country—a fact due to the pernicious influence of the late Gleeson White, a half-educated man and a self-educated dabbler in the arts, whose notoriety was due entirely to art journalism. All these experiments have done a world of good in that they have proved to the hilt the fallacy of various pictorial theories and the inferiority of various methods, and they have given rise to various improved printing papers which lend a variety to our exhibitions.

But it all comes back to what I advocated twenty years ago—that is, the good lens, the good negative, and the printing processes of platinotype, carbon, and photogravure. The bromide print does not, I think, equal any of the above printing processes; there is a lack of quality in the print and a coldness and hardness in many that are unpleasant.

It has been proved undoubtedly that the taking of the negative is a pure science, and the printing, too, for that matter, so that the pictorial photographer is reduced to an elegant selection of subject and focus, and a choice of colour and grain in his papers. I still prefer the best photogravure process to any other, and carbon and platinotype to all other methods.

Pictorial photography is a useful and pleasant liberal art

for those who cannot draw or paint, but all the ever-recurring claims made for it as a fine art are doomed to disappointment, and many even of the most enthusiastic and far-seeing amateurs agree with this verdict—which will be the final verdict

DR. P. H. EMERSON,
The founder of modern pictorial Photography.

of the world, as it has been already of the best artists. And the next Jubilee of THE BRITISH JOURNAL OF PHOTOGRAPHY—that slayer of many of the fads of the day—will find my forecast, I am convinced, correct.

P. H. EMERSON.

New Bruce Telescope at Yerkes Observatory.—Yerkes Observatory has received its new Bruce telescope, and our readers will be interested in a brief description of the instrument which came to us from one of the observatory staff:—"It is a splendid piece of work—as all of Warner and Swasey's is. It is a triple mounted tube, a 10-in. doublet, 50 in. focus, by Brashear. A 64-in. Voightlander doublet of 31 in. focus, and a 5-in. guiding telescope, object glass by Brashear. The mounting is somewhat similar to that of the Potsdam telescope, but a great improvement on that mounting. The pier is bent to form the polar axis, so that the system of the telescope can swing free when crossing the meridian in any declination, so that a continuous exposure can be made from horizon to horizon in any part of the sky. The telescope is placed in a small but handsome observatory made especially for it."

Half a Century of Camera Evolution.

E VOLUTION may be defined as a process in which, by a series of continuous progressive changes, a complex arrangement is developed from rude or simple beginnings, and it is, therefore, a term which may justly describe the genesis of the modern camera.

Fortunately or unfortunately, I cannot recall from personal knowledge every type of camera that has been used during the last fifty years, but a study of such records as are available in

Photo by]

E. J. WALL, F.R.P.S.,

Author of "The Dictionary of Photography."

(Platinotype Co.

the shape of encyclopædic text books, and the most entertaining and instructive portions of the average photographic journal, the advertisement pages, to wit, has led me to endorse the cry of the Preacher of old, "and there is no new thing under the sun." There is no existing camera that has not its prototype in the early days of our science, and from an examination of the evolution of the camera one might construct a chronological table of the advances in photographic knowledge, always bearing in mind that the camera has followed the requirements of the sensitive material, and never the reverse, for in no case that I can recall has a camera been designed and then a sensitive material found for it.

Let it not be thought that I am depreciating in any way the ingenuity which has given us the modern camera, but one cannot ignore the fact that as the replacement of the Daguerreotype plate by paper supports gave an impetus to outdoor work, largely increased as this was by the introduction of the wet and dry collodion processes, so the gelatine plate placed within the reach of the million, photography as a hobby and led to the construction of cameras of a lighter and more portable type, and at prices which may well make some of the old makers turn in their

graves. The hand camera may, at first sight, be said to be the outgrowth of the gelatine plate, but this is not correct, for hand cameras, and fixed focus cameras too, were known as early as 1860. The popularity of the hand camera is alone derivable from the gelatine plate and its reduction in price.

Probably of all types, the studio camera is that which shows the least advance, and necessarily so; it is not required to be light and elegant for transport, but rather of solid construction, combined with elegance of appearance, if you like, for its nomadism, if one may use such a term, is confined to a few feet of floor space in the studio. True, that the modern studio camera is not the wooden box, with either fixed or sliding body, which one naturally associates with Daguerre or other early pioneers, and which one still finds so often as the instrument of the beach and wayside and always associated with that peculiar construction, which has, I believe, been called a rabbit hutch on wheels; but the bellows body cannot be said to be a product of the last half century, for such was known in 1839.

Individual parts of the studio camera have been improved; elaboration of the front and back movements, refinements in methods of focussing, and, above all, increased facilities in working the stand, which must, I think, be considered as an essential of the camera, an integral part of the whole. The double slide and the repeater or multiplying back are, however, products of this last half-century.

The historiographer of the camera is yet to be born, or found. His work would be tedious and ill-requited, but if carefully done it would at least prevent some infatuated inventor patenting a device that was in use probably before he was born, as I noted occurred only a few weeks ago, when some one, no doubt in all honesty, discovered that a mirror placed at an angle of 45 deg. behind the focussing screen would revert the inverted image, a device that is stated to have been used by Daguerre in 1839; and this is not the only instance that I could name, not only in connection with the studio, but every other type of camera, so that one has to ignore minor details and consider main ideas.

The tourist or portable camera shows evidence of far more ingenuity and radical transformation than the studio camera. Here, lightness of construction, combined with elegance and reduction in price, has reached such a stage that one is inclined to doubt whether there is yet any further chance of improvement. The introduction of collodion by Scott Archer in 1851, but three years prior to the commencement of our half-century, at once gave the necessary impetus to lighter construction, but the light tourist cameras of even those days would astonish by their weight and absence of accessory movements the latter-day amateur: the bellows were oblong, and to reverse the picture the whole apparatus had to be turned on its side; the front and back were without movements of any kind. Then came the Kinnear or conical bellows, made first, I believe, by Meagher in 1861, with swing front and swing back and side shift, then the reversing back, the rising and falling front, and finally the turn table, at first solid, as was also the base board, and then finally the cut-out turntable and baseboard still further reducing the weight; the screw-rising front, the plumb indicator, levels, and the long extension, the shifting back and front for very short-focus lenses, are all merely the evolution from the simple and rude box camera; in fact, the adaptation of the instrument to the altered circumstances of the present day.

In one particular only has the camera, or, rather, an appurtenance thereof, remained practically the same for the last fifty years, and that is the dark slide. The exact date of the

double dark slide, which took the place of the single, I have been unable to trace; at any rate, by 1860 they were in common use, and have approximately retained the same form, though there is generally less waste of timber in their construction. Changing or magazine boxes date back at least to 1860, whilst changing tents, if one may include these, are as old, if not older.

Flexible, supports, which, be it noted, please, are not of mushroom growth, naturally turned the inventive mind to special forms of carriers, and a rigid support with an adhesive material for the holding of the flexible sensitive material dates back to 1856. The convenient roll holder was first suggested by Relaudin in 1855, and Melhuish in the following year, Burnett in 1857, Audineau in 1862, and Warnerke in 1875 also devised these instruments, which were all designed for negative paper, as was also the original Eastman roll holder, but it was not till the introduction of celluloid that their use became general, and probably at the present time they have again sunk into somewhat comparative obscurity or are limited to the smaller sizes and used in hand cameras alone.

Finders, certainly of the well-known camera obscura form date from about 1854; the so-called "brilliant" type are of much later date. View meters, or iconometers, again take more or less elaborate forms, but a simple and effective one was suggested by Taupenot in 1855 under the name "chercheur photographique."

Multiplicator, medallion, cameo, and stamp cameras show but little change since Quinet's apparatus of 1854, or Southworth's, of Boston, apparatus, patented in 1855, with which he reckoned to be able to take no less than 50,000 prints in an hour, using ten plates on which were 6,160 negatives. It is needless to add that the pictures did not measure 15 by 12 each.

Panoramic cameras, and I limit this term entirely to instruments in which the image is received on a sensitive surface bent to the arc of a circle, date back to 1854, when Martens, a copper-plate engraver used curved daguerreotype plates, and later Chevalier, Stebbing, and Moessard perfected this type. Under this or similar names many forms of cameras were used for obtaining panoramic views on flat plates, and lately the principle has also been applied to hand cameras with celluloid films.

Of all cameras, I think the one that has shown the least advance is that for stereoscopic work; probably from the well-known neglect of this fascinating branch, manufacturers have been content to rather accept a given type than perfect it. Not that I have for one moment lost sight of the fact that many of the first-class tourist cameras of the present day can be adapted for stereo work, but the stereo camera *per se* is, so far as I know, somewhat antiquated.

With regard to photogrammetric cameras, or photo-theodolites, I can only say that not a year passes hardly but what some improvement is effected. They are special and wonderful instruments for special work; their introduction is decidedly recent, if one may consider anything produced first about twenty-five years ago as recent, and to indulge in a sketch of the improvements effected of late would entail more space and more diagrams than the Editors probably feel inclined to allow me.

Chronophotographic cameras again comprise such a vast field that it is impossible to give any adequate idea of their rise and evolution from Fox Talbot's first suggestion in 1851, through Skaife's pistolgraph (1860), Thomson and Enjalbert's revolvers (1862 and 1882), and Janssen's astronomical gun of 1874, to Marey, Muybridge, Friese-Greene, Edison, and others; the final outcome being that class of camera known by so many names, but which may be generally described as kinematographic.

Other special forms of cameras there are, such as photomicrographic, astronomical, and those for other particular classes of work, such as colour photography. It is enough to mention

them and leave the reader of these lines to fill in a mental picture of the developments of the same.

To the last I have left that class, numerous in type and size, and almost daily increasing both in number and variations, which is known as the hand camera, which is not a product of latter-day photography. In 1860 and 1861 fixed focus hand cameras with wood or metal bodies were made by Bertsch and Ottewill, and a collapsible pocket camera with cloth body was suggested by Edwards in 1855. Sutton suggested in 1860 the reflector principle, though it was rather suggested for stand cameras. A twin-lens camera was used by Disderi in 1864. Magazine boxes and magazine cameras for stand work were known in 1861, but Pumphrey, in 1881, seems to have been one whilst Enjalbert, in 1887, used a lifting lever and leather bag attached to the camera. Bolas, in 1881, described the first hand camera with focussing arrangement, magazine, with twin-lenses and a prism in front of the lens so that the camera need not be pointed at the person who was to be taken; he also used a pneumatic release and invented the term "detective camera."

In the early days of such cameras the main idea seemed to be to devise the externals so that as little notice as possible should be attracted, and the semblance of luncheon baskets, books, brown-paper parcels, etc., was used; small cameras were put in bowler hats and under the waistcoat; but now all that is changed, and the hand camera is openly and without shame flaunted in the face of all.

It was but natural that the introduction of celluloid films should lead to increased use of cameras with roll holders, and I believe that the Eastman Company were the first to introduce that type of camera in which the roll holder was an essential part of the camera, either in the fixed focus box form and later in the folding pocket type with extensible bellows; the former dating back to 1888. That particular type of camera, so much in favour on the Continent, and known generally as the Jumelle, obviously took its rise from the opera glass, and cameras having the actual form of an opera or field glass are yet not unknown, though patented in 1881.

Since 1854 the evolution of the camera has proceeded on regular and well-defined lines—namely, the perfection of detail with corresponding ease of particular movements, or the attainment of given ends and a cheapening in price; what the next half-century has in front of us time alone can show, but at first sight it is not easy to see in what particular direction great improvements or radical changes can be effected, for with the wide spread of photography and consequent great demand, many minds are directed to this subject, and the introduction of machinery has so cheapened production that even in this respect there is little to be hoped for, but if any great advances

E. J. WALL.

THE death has taken place at Oldenburg of Herr R. Schwartz, who claimed to be the inventor of the picture postcard.

WE much regret to learn of the death of Mrs. Staley, the wife of our old friend, Mr. A. E. Staley, of Thavies Inn, Holborn Circus, London. We offer Mr. Staley our sincerest sympathy in his bereavement.

THE Biggest Anastigmat in the World.—During a recent visit to the optical works of Messrs. Ross, Ltd., at Clapham Common, we were shown what is probably the largest anastigmat in the world in course of construction. The focal length of this giant lens is 6 ft. (72 in.). The definition given at full aperture was perfect, and the lens, which is of the well-known Homocentric type patented by Messrs. Ross, will cover a plate 6 ft. square sharp to the corners. The lens, as we saw it in an unfinished condition, weighed over half a hundredweight, and needed as much careful handling as a baby. We presume this colossus among lenses is ultimately intended for process work.

"Reminiscences."

TO-DAY, May 27, 1904, I note the number of the BRITISH JOURNAL OF PHOTOGRAPHY is 2,299, and I can scarcely realise that since I received at my studio, in Bath, the first number of the same, then called "The Liverpool Journal of Photography," and a note from Mr. Henry Greenwood asking me from time to time

H. N. KING,

One of our oldest and most experienced professional photographers.

to contribute to the same, that half-a-century has slipped by, since then what changes; but excellent work was produced in those days. The Daguerreotype and paper negatives were practically ousted by the Collodion process. This, to me, was of intense interest, and I worked hard with experiments and in the manufacture of Collodion was very successful. Many of the present day imagine that the productions of forty or fifty years ago were very poor, a greater mistake was never made. The landscape work produced in the fifties and sixties have never been excelled. Take the 12 by 10 work of such men in those days as Bedford, Vernon Heath (the whole of his landscape negatives 12 by 10 are in my possession), William England (an old schoolfellow), and his statuary, Swiss scenery, etc., and many others also produced work of exceptional brilliancy and marvellous detail, results not excelled by any work of the present day. The carte de visite follows and brings grist to the mill of the photographer; the rage was immense and the whole sale price was 8s. a dozen. My connection with the musical and dramatic profession enabled me to secure an enormous number of celebrities, and tens of thousands of the same were sold. I have before me an order from the firm of Marion and Co., signed F. Bishop, to the late Vernon Heath, dated 11/7/67.

for eleven thousand copies C.V. of the Prince and Princess of Wales, one or two negatives were of little value to meet the demand for copies. I had a camera made 10 by 8, fitted with three Dallmeyer lenses, giving at one exposure three negatives on the half of the plate 8 by 5 raising the back a second exposure varying the position or not gave me half-dozen negatives. With many sitters, such as Sayers, Heenan, Blodin, Livingstone, and others, I secured three or more plates. After exposure and developing the plate washed I coated with glycerine and put aside in boxes till the day's rush was over when the necessary time could be given to proper fixation or intensification if necessary.

The stereoscope at that time was in great demand. You could scarcely enter a house without seeing on the drawing-room table a stereo and slides, the sale being very large. There is a fascination in a stereo slide, the reality of the scene portrayed especially in a glass transparency, which I have for many years tried to make popular. I can only compare my love for the stereoscope to that of a child with a doll, idolised and worshipped as it is in infancy. Later on the sale fell off, and I have not the slightest doubt the results of the indecent slides produced. For years it was a dead letter, and until recently the present generation knew nothing or but very little of the stereoscope. A great revival has again taken place, but I regret there is again the same tendency to produce objectionable slides. I can only hope that the strong arm of the law will put down and punish the producers, otherwise the results of previous years will repeat itself. The same thing, I regret to see, is being introduced in postcards. This branch has caught on immensely and must give employment to thousands. Cannot the stationer, for his own sake and benefit, be persuaded not to purchase anything bordering on the slightest tendency to offend. The very rapid growth of various processes in half-tone collotype colour work, etc., the enormous number of albums of such in packets also of almost every town has, with the postcards, played sad havoc with the sale of legitimate photographs, albumenised and other processes. I do not hesitate to say no publisher of note has one-tenth part the sale of the thousands he may have in stock to that of a few years back; specialities only have a sale. The photographic publisher has now to fall back and keep pace with the requirements of the day. Note now the photo-scenes as advertisements at railway stations and carriages. I claim to be the first to try to introduce photographs in railway carriages. Forty years ago I had interviews with the heads of the Great Western, Midland, South-Western, and other companies, endeavouring to show the attraction of the various views at stations on the line has an inducement to visitors which, I felt sure, would secure to them passengers. The Great Western favoured the idea most, and without binding themselves to carry the scheme out, and granted me two first-class passenger and luggage free for six months—luggage for 12 by 10 wet plates, no joke in those days. I could travel and stay at any station on the railway. I made one tour from London and towns to North Wales, a second one London to Devonshire, obtained a large number of excellent negatives, but the company thought the cost for prints, frames, etc., would not be at that date advisable, but gave me permission to place a frame at any or all stations without charge at the various waiting-rooms. I could not see my way to get a return in this way and had to content myself with the negatives; but the same afterwards yielded a good result. Illustrated papers and magazines bring an addition to the income of the photographer, although at a serious loss on the sale of prints. I well recollect forty-six years ago photographing the planting of the Russian guns in the Victoria Park,

Bath, a copy of this appears in the "Illustrated London News" of September 28, 1858. I had an interview with Mr. Ingram, the founder of the "News." At that date he was not in raptures with photographs for illustration. "Mr. Ingram," I said, "the day will come when the public will not be satisfied with the inaccuracies and incongruities of the artist with the brush. They will demand the reality of the photograph and its truthfulness. This will increase to an enormous extent illustrated papers and magazines." I think there can be no question of doubt that such is the fact, the immense piles of these at the bookstalls tell the tale. In conversation with Sir William Ingram, of the "Illustrated News," I mentioned my interview with his father and asked him had such been the case? He replied, "Mr. King, you are a good prophet; they could not exist without its aid."

Perhaps no better argument can be found respecting the rapid increase of photography than by, as an illustration, the *BRITISH JOURNAL OF PHOTOGRAPHY*. Compare an early number with that of the present day. The immense increase of advertisements in every way and the literary matter. Note, as a curiosity, the first number of the "Almanack," which is before me, and contrast that with the last, forty years later. The one published in 1864 measures 4 inches by $2\frac{1}{2}$, $\frac{1}{4}$ of an inch thick, and 72 pages of matter, weight 7 drams; now take the 1904 (forty years later), size $7\frac{1}{2}$ by 5, thickness 3 inches, weight $3\frac{1}{4}$ lb, pages 1,804. The whole of the forty "Almanacks" I have, and they contain articles of great value, and many as well have the numbers of the *JOURNAL*. Inventions, many of which by a little manipulation are the recent discoveries now brought out, and it is a very difficult matter to find any process or apparatus not dealt with in some shape or form, whether panoramic cameras, pistolgraphs, or snapshots; they contain articles invaluable and interesting. Look again at the enormous increase of photo literature, the publications of Snowdon and Ward, Iliffe, and others on every conceivable subject connected with photography. Hardwicke's

Chemistry and Brewster on the Stereoscope were my earliest treasures.

It is now many years since dry plates were introduced. I think it was 1855 I first used Dr. Hall Norris's dry plates. Then we had the Tannin process of Major Russell, the Collodion Emulsion of Joyce and Bolton. Practically wet collodion held its own until 1881, when gelatine plates took the lead. Since that date they have been vastly improved, and, if I may advise, let the plates you use be orthochromatic. The work in the collodion days was very laborious; that of the present day is very different. I have frequently to make long journeys with 12 by 10 camera and invariably return with a large number of plates, but I have never during the last twenty years, except when working at Windsor Castle, developed a plate away from home, whether my journeys have been England, Ireland, Scotland, or Wales.

Now, looking back with pleasure to early days in the practice of the art, there are times when sadness creeps in. I feel the loss of many eminent men in photography it has been my good fortune to be associated with, exchange ideas, etc.; names amongst them probably unknown to many of the present day: Claudet, Fox Talbot, Mungo Ponton, John Beattie, Sarony, Bedford, Wharton, Simpson, Trail, Taylor, Dr. Thompson, Hughes, Vernon Heath, Mayall, Sutton-Rylander, Robinson, Hardwich, Lake, Price, Glacier, Breeze, W. B. Bolton, Warner, etc.

For a moment a look at the bright side. There has not been during the last fifty years a discovery more useful or interesting than photography. Its productions abound in the palaces and home of the cottager; used alike by the arts and sciences, by the detective to aid the means of justice, by the antiquarian to preserve as mementoes relics of those buildings now fast mouldering away by the hand of slow, wasting time, giving employment to tens of thousands and delight to the same.

HORATIO NELSON KING.

Photography as a Hobby: Does it Pay?

DOES it pay? Probably few amateurs of any standing in photography have escaped the responsibility involved in answering this question. One way of evading it is to ask, "Does any hobby pay? Is it expected of any pursuit adopted as a recreation that it shall 'pay' in the material sense of the term?"

But if satisfied that the query is merely intended to elicit an opinion as to whether photography yields an adequate return in interest and enjoyment for time, labour, and expense devoted to it, one need not hesitate to venture upon an emphatic assent.

The kind of pleasure derived from the pursuit of photography, and whether it tends to the elevation of personal character or the reverse, depends, as in many other cases, upon individual temperament. Consider how various an element is here implied,—that "one man's meat is another man's poison,"—that one is earnest and thorough in all he does, and another but superficial,—that one finds his highest joy in life in posing before his fellows, while another seeks by every means to shun the public eye,—that one finds his whole interest in the scientific principles underlying an avocation, while another delights in its powers of ministry to the gratification of the æsthetic faculty, and so forth,—and when it is recognised that photography has something to offer of pabulum acceptable to all these types of character, it will necessarily appear that the moral product must vary according to the nature of the individual, as has been said.

Yet in most cases the individual will be found to assert that photography has answered his purpose. It has opened a way to easy attainment of that wherein his soul delighteth.

The earnest student will realise that he has entered upon a life work of experimental research of most absorbing interest. The superficial discovers that he has only to "press the button" in order to collect memoranda of all that catches his fleeting fancy. The *poseur* is furnished, by the particular "mutual admiration society" honoured by his membership, with frequent access to a moral or material platform. The retiring of disposition can enjoy the prosecution of his experiments in solitary seclusion. The scientist finds himself confronted with problems, chemical and physical, as fascinating as he has ever encountered. The artist is delighted to discover himself in possession of a new medium of expression, of powers and characteristics unfamiliar, but of special value and of facile application. And so on to the end of the category; and therefore it must be concluded that, as a hobby, photography does "pay," in some acceptable form of *kudos*, the great majority of those who engage in it.

But "there's a deal of human natur' in man"; and, as he cannot be definitely classified according to the foregoing or any other scheme, suppose we limit the scope of our inquiry, and ask what inducements and rewards photography holds out to an ordinary individual possessed of average intelligence and culture?

It is probable that the successful outcome of a first exposure is always productive of a pleasurable mingling of surprise at the facility of the operations by which it has been brought about, and of self-gratulation upon the evidence afforded of some power of judgment by which similar or even better results may be accomplished in future. There is usually encouragement, at

J. T. ASHBY, F.R.P.S.,

A well-known and much esteemed photographic judge and critic.

least, to a second adventure, even though greater care in carrying it out be inculcated by some little slip in the first. And further endeavours, carried through with ever-increasing circumspection, and leading thereby to more pronounced success, conduce to a habit of thoughtful care in every undertaking, together with a wholesome optimism as to the rewards of that homely virtue.

But meanwhile the operator is also acquiring a new faculty, and is unconsciously training himself in its exercise. He is learning to see, to substitute the habit of accurate observation for that of the vague visual exercise which passes for seeing with so many of us, and which leaves only a confused general impression upon the mind. He is beginning to master the niceties of contour and the subtleties of gradation, and to appreciate the endless varieties and the beauty of texture.

And this larger faculty of vision is accompanied by fuller understanding and naturally conduces to the ripening of the selective faculty also.

This is the stage at which the student begins to be conscious of his new powers. He begins to know *why* he does this or that in arranging his subjects or in selecting his point of view.

And now he finds his hobby not merely an education but a source of continual delight, and an "exceeding great reward."

If, at this point, he be so fortunate as to fall under sound guidance, he seizes with avidity upon the principles laid before him. They supply him at once with an explanation of the phenomena he has observed and with a key to their æsthetic significance in pictorial combinations. Left to himself he might be longer in arriving at similar conclusions, but he would probably reach them in the end, if not led astray by the charlatans that beset the way of the amateur at this period of awakening consciousness and sensibility.

The writer would seriously advise all whose experience he has sketched above and who have, however modestly, begun to realise that the practice of photography has awakened some sense of artistic instinct within them, to study some such simple handbook on pictorial composition as Green's "Sketching from Nature" or Harding's "Pencil Drawing," supplemented by either of the handbooks of the late H. P. Robinson bearing upon the same subject. Above all things he would enjoin them to be loyal to the characteristics of their medium, photography; to use no smudgy and gritty process inadequate to the expression of the really fine pictorial qualities of pure photography, but to leave all manipulations that tend to gloom and grime to the purblind charlatans aforesaid.

Encouragement and assistance may often be derived from joining a local photographic society, or from membership of a postal club, always providing that the fraternity be not dominated by faddists. These gentry may usually be known by their pretence to greater æsthetic sensibility than their neighbours possess. They will eulogise painters whose renown is based upon the technique of their art in one breath, and in the next they will denounce photographers who excel in the technique of theirs. Their utterances run either to Velasquez and Whistler (if you have studied these matters note the incongruity! this is only a sample,) or else to "indefinable something" which are to be understood as too exquisitely exquisite for expression in language. They remind one of Æsop's young "mole" who was reprimanded by her "dam" for an affectation of sensibility likely to lead others to suppose her completely destitute of common sense.

Exhibitions, and the competitions conducted by some of the photographic journals offer means of comparison with the progress of other workers. But do not work, compete, or exhibit merely for notoriety. As soon as delight in one's work for its own sake begins to flag,—as soon as the constant stimulus of successful competition or of popular applause becomes necessary to the maintenance of one's interest in a pursuit, that pursuit is beginning to lose its wholesome and legitimate influence as a hobby.

This is incidental to every form of human recreation. Ever racing is said to develop some vague tendency towards the subsidiary excitement of betting, and we have heard that innocent speculation as to the permutations possible in a packet of fifty-two pieces of painted pasteboard may be made contributory to the gratification of the gambling instinct!

Seriously, however, the greater benefits of amateur photography are not to be secured by its exploitation for self-advertisement or for material gain. But so long as it is followed for the sake of that ever-growing delight in the beauties and the wonders of creation to which it ministers, so long will it "pay," and repay a thousand-fold all the outlay of its votaries upon it.

It pays in the mere form of an urgent inducement to physical exercise which might otherwise be neglected. It pays in the educational and elevating influences to which we have directed attention. It pays as a recreation by reason of the absorbing interest it excites and thereby securing many a respite from the cares of our ordinary occupation.

And thus it will continue to reward its followers, unless and until egotism be allowed to step in and obscure the artistic vision.

J. T. ASHBY.

Thos. Bedding, Esq., F.R.P.S.

My Dear Bedding,—To be invited to contribute to the Jubilee Number of your important journal is a distinct honour which I accept with cordial appreciation of the friendly terms in which you tender it.

I fear that neither you nor I are likely to witness the centenary of the BRITISH JOURNAL, but my confidence that there will be such an event, and that it will mark the completion of another fifty years of indispensable service to the world of photography, is based upon the position your labours have established for it.

Your suggestion that I should contribute a picture or two is one that I would willingly comply with, but it only reached me here; and although I am returning to-morrow, I cannot get anything to you before Monday. If, therefore, you are able to use it, it will be a triumph of rapid-reproduction. But I doubt whether even the

marvellous resources at your command will enable you to accomplish that.

This is an earthly paradise, as you know; but the weather—well, consolation is to be found, and I wish you were here to share it with me “to the success of the B.J.!”

In spite of bad weather, I have added considerably to my collection of “bits” lying out of the ken of the ordinary tourist, and my daughter Beryl, who came down “to take care of” me, has found *Trollius Europæus* and a few other rareties blossoming in profusion.

Wishing every success to the Jubilee Number, to the JOURNAL, and to its Editor,—I remain, my dear Bedding, yours sincerely,

J. T. ASHBY.

Glan Aber Hotel, Bettws-y-Coed, North Wales, May 27, 1904.

Handling the Adult Sitter.

THE editor of a photographic journal is naturally a much-photographed man, and during the past twenty-five years I have probably been “took” more frequently than even the most popular professional beauty or the most abandoned criminal. With such opportunities for observing the ways of operators one is able to form an opinion as to whether their methods are improving or not, and as to changes and fashions which may be good or bad. In one particular direction the improvement has been very great. Probably it has been largely unconscious on the part of the operators themselves, and it has taken place at varying rates of speed in different studios and in different districts. In fact, there were some men, twenty-five years ago, whose methods were pretty nearly those of the most advanced men of to-day; and there are still a few operators—very few, I believe—who are working just as they did (or as their employers did) a quarter of a century ago.

The particular phase of operating to which I refer is the posing of the sitter, and its traditions have gone through three principal stages:—

1. The sitter is posed by the operator.
2. The sitter poses himself, knowingly, at the instruction of the operator.
3. The sitter poses himself, unconsciously, at the suggestion of the operator.

The first method flourished in the day when people compared sitting for a portrait to a dental operation, and although this was a libellous comparison, there was, as we now know, an unnecessary amount of pushing and pulling, of wheeling about in castored chairs, of changing accessories and backgrounds, and, finally, of fixing with head-rests, back-rests, body-rests, and even, sometimes, hand-rests and elbow-rests. In this method the head was raised and turned and twisted, the arms and legs, even the hands and separate fingers, were laboriously posed and arranged, until no human sitter could possibly retain an easy attitude or an interested expression.

When it became the fashion to allow the sitter to do most of the posing, at word of command, a very great step had been taken. Of course there are, and always will be, some sitters who cannot do even such a simple thing as “raise the chin just a little,” or “turn the eyes this way without moving the head”; but with most people this sort of thing answers much better than personal handling. By arranging the lighting beforehand, by deciding the position for standing, or placing the chair for the sitting figure, and by selecting a chair of which the height, depth, and especially the positions of the arms properly fit the sitter, and then by a few words suggesting

that the head should be raised, turned to the left, the hand drooped over the chair-arm, and so forth, a sitting may be made very short; the sitter is interested rather than bored, and the pose and expression have a good chance of being satisfactory.

But there is yet a further development of method; a system in which the sitter does the whole of the posing without being asked to do so. It is the most valuable art an operator can acquire, and for its highest development it needs the intelligent co-operation of one assistant, or even of two assistants, with the operator. The art is based upon wide observation of humanity—of both physical and mental characteristics. The fact that familiar attitudes are easily taken, while unfamiliar poses are always stiffly held, is perhaps the most important basis of success. This fact makes it desirable to know something of the sitter's tastes and avocations. A lady who re-

H. SNOWDEN WARD, F.R.P.S.,
Editor-in-Chief of “The Photogram.”

gularly rides horseback will naturally hold her arms and shoulders and head well poised if she is given a rather high seat, with no temptation to lounge, while a man who spends most of his time in writing will always most easily take a

position in which there is some support for his fore-arm, even if it is only on the arm of a chair. The effect of the seat upon the carriage of the whole upper part of the body is important. Many a sitter, if placed in a low chair, especially if it is soft and easy, will at once lounge, curving the spine, dropping the shoulders, and drooping the head; but if seated on a fairly high stool or hard-seated chair, will hold the body, shoulders, and head in a good, but not stiff, position. Further, even with a sitting pose, a change so simple as the placing of a hassock under one foot will cause a slight alteration in the whole pose of the body, bringing up a shoulder that drooped, swinging the body round a little, and changing the poise of the head. These facts, and a thousand-and-one similar, are part of the stock-in-trade of the first-class operator, who needs observation, reflection, and good memory, that he may know how to get the effects he wants without much experimenting on any individual sitter.

For securing a turn of the head or eyes, the discussion of some object (a picture, frame, piece of bric-à-brac, or even the war or weather) is better than a direct request. With sitters who habitually look straight at the person they are talking to an abstract subject is sufficient, but with those who usually avert their eyes, some definite object, not too large, is useful. Such an object should not be introduced until just before the exposure is made; and then, if the exposure is long, an unpleasant stare may be avoided by moving the object a little

nearer to, and further from, the sitter, keeping it in a line with the direction of gaze. Thus the eyes are prevented from moving (without need to tell the sitter to keep still), yet the direction of their axes is changed just sufficiently to prevent stare.

It is never well to let your sitter know that you are dissatisfied or unsuccessful. If the first few dodges fail, instead of continuing for a long time trying change after change, it is well to make (or pretend to make) an exposure, then let the sitter walk around for a moment or two, discuss some object of interest, and begin again. In this way fatigue and stiffness are prevented.

These are pieces of common observation on which the model operator bases his success. Each must make his own rules and methods, and must vary them for every sitter. The development of the "suggested" pose, to replace the pose which was "made" and that which was "requested," is one of the greatest advances made in photographic portraiture during the half-century; and I doubt whether any of the improvements in technique are really so important. The cultivation of the method of posing seems the one thing most desirable for the successful operator, and I believe it will do more than anything else for the introduction of real artistry into our portraiture photography.

H. SNOWDEN WARD, F.R.P.S., Editor of "The Photogram."

Contrasts.

PHOTOGRAPHY enjoys the unique distinction of being the only business everybody seems determined to teach everybody else. But, it was *not* always thus. I cannot go back photographically to the date of the first number the BRITISH JOURNAL is jubilating over,

F. A. BRIDGE,
Hon. Secretary and Treasurer of the Photographic Convention
of the United Kingdom.

but at any rate I can personally testify to the great changes which have taken place during thirty-five years.

Then, amateurs were scarce and books on photography were few; now, amateurs are everywhere and books on photography are as plentiful as the most ardent votary of the camera could desire. Then, the number of reliable books might have been counted on the fingers of one hand, and were written by well-known professional photographers and scientists; now, there are possibly number 250, and have been written by "all sorts and conditions of men." In fact, I cannot help thinking that if the legitimate occupations of many of the authors was made known it would come as a surprise to many people, and there would be a considerable slump in photographic literature.

In the old days, amateurs consisted mainly of a few ardent souls who did not mind staining their fingers. Now, photography numbers among its votaries kings, queens, and princesses, and the very idea of connecting Royalty with stained fingers is too dreadful to contemplate.

Then, all the photographic societies in England and Scotland combined numbered about eight; now, the number in Great Britain and Ireland alone totals up to nearly three hundred. Almost every town at the present time has its photographic society, and when I think of the secretarial labour involved in keeping the meetings going after the novelty has worn off, and the members have exhausted each other, I shudder. Yes, I have had about twenty-five years of this sort of thing in one form or another, and know what it means. If the members, after suggesting subjects, would only come to the meetings and discuss them, it would be all right—but, how many do? Then the poor honorary secretary tries to find attractions in the affiliation slides and trade demonstrations to eke out his season. Even then, his well-earned leisure is encroached upon by the arrival of packets of prospectuses, leaflets, and prize-lists, which manufacturers in their innocence (bless them!) flatter themselves

will at once proceed to distribute to his members, and thank him "in anticipation." But, let us go back to 1870. Then, advertising was confined principally to the two journals, and the advertisements were plain and easy to comprehend. Now, they are sometimes such mythological fairy tales, that it requires a key or "argument" before the beholder can form the slightest idea of their connection with photography. Then, the choice of lenses was practically confined to the portrait, the rectilinear, and the single landscape, and the introduction of any new form by a well-known maker created quite a sensation. Now we have a formidable array of "stigmata," and our good old friend the rapid rectilinear has been re-christened a dozen times over.

By the way, one of the latest "novelties" in the way of lenses comes from America. It is called "The New Century Wonder," and we are told it is so constructed that it will change its focus by a mechanical separation of the lenses during exposure, and produce such a soft and diffused result that retouching is unnecessary. I do not happen to know of what the optical combination of this novelty consists, but a portrait lens on this principle was invented and used by Claudet some forty years ago.

Those who have only taken up photography since the gelatine dry plate period can form but a faint idea of what it was in the wet plate days; particularly in connection with outdoor work. A careful of luggage was a necessity. The plates were prepared and developed in a tent on the spot, and exposure meters were unknown. Cameras were mainly of the box-type and very heavy. Kinnear came to our aid a little in this respect, but that thing of beauty, the modern camera as we see it in our dealers' windows, with its eccentric movements and its reversing back,

had not then been dreamed of, and the word Kodak had not been invented.

Speaking of the reversing back, I am reminded of a meeting of the old South London Photographic Society when a visitor showed an unpolished piece of apparatus, the advantage of which everyone present immediately recognised. It was the reversing back practically as we have it now, and if the inventor had patented it it would have been a gold mine. Another matter might be mentioned here. I do not know who was the first to put the idea into practice, but the suggestion that a piece of opaque paper at each end of a roll of sensitive material would enable it to be changed in daylight, was first made at a meeting of the old S.L.P.S. as far back as 1886.

Five-and-thirty years ago photography was often alluded to as the black art. Then it was called an art-science; now, by many it is regarded as an art (without the science), and in some cases I must admit it comes very near to being so. A few enthusiastic workers in 1875 included it in this category, and made an effort to found a "Photographic Art Union"; one of the originators of the scheme being the present president of the Royal Photographic Society. Then, there was only one exhibition worthy of the name, and that was held annually by the Photographic Society of Great Britain, whose contributors prided themselves on the brilliancy and sharpness of their results. Now, almost every society has its periodical show and—but, no! there is a limit even to the capacity of a jubilee number, so I'll finish my contribution by wishing long life and continued prosperity to the BRITISH JOURNAL OF PHOTOGRAPHY.

F. A. BRIDGE.

The Last Word on Half-Tone.

PRACTICALLY all the history of photo-engraving is comprised in the records of the past fifty years, for though it is ninety years ago that Niepce practised his bitumen process on pewter plates, which was the direct forerunner of all photo-etching processes, and Mungo Ponton discovered the principle of the bichromate processes sixty-six years ago, there was little done towards applying photo-mechanical ideas to commercial work until well into the fifties, whilst it may be truly said that it is only within the last ten years that process work has achieved its most practical developments.

My own acquaintance with photo-mechanical processes dates from 1880, and, looking back, it is interesting, if somewhat saddening, to recollect even in that period the many processes which have run their brief career, the businesses that have been founded and wrecked upon them, and the money which has been spent in attempting to exploit them; whilst, saddest of all, is the passing away of many whose bright intellects were lavishly expended on such processes. Having come into contact either personally or by correspondence with a large number of inventors of new photo-mechanical ideas during the last twenty to twenty-four years, a retrospect brings to mind many interesting reminiscences; but I fear I might be reflecting on the memory of many who are now gone, and possibly hurting the susceptibilities of some who are still living, if I were to write as I at first thought of doing, a gossip account of past processes. And, after all, why rake over the lumber-room of the past for details of these superseded methods? The "living dog is better than the dead lion," and the healthy, vigorous life of process work to-day furnishes theme enough for an article.

I am sometimes asked whether it is possible that the half-tone process can make any further developments. The process seems so perfect in its results, and so precise and simple in its method, that it is difficult to conceive what more can be done. I am far from agreeing, however, that the last word has been said upon it. As a matter of fact, very little experimental work has been done on the half-tone process of late. Those in the trade have been content to let well alone, and, having a hard struggle to make things pay at the low prices now current, they have had little temptation to step out of the beaten track. Those who have had the time and inclination for experimental process work have given their whole attention of late to the three-colour process, confining their efforts, moreover, to the question of colour filters to the neglect of what may be an equally important consideration—viz., the influence of the ruled screen on the colour rendering. Only of late have a few far-sighted workers begun to see that a much more perfect result in three-colour blocks is obtained by a finer ruling, and where 150 lines was formerly in vogue the tendency is now to adopt 175 lines.

There can be no doubt that the scale of gradation is considerably influenced by the ruling. With coarse screens it is well known that hard contrasts are obtained, whilst fine screens tend towards flatness or softness, although holding more detail. The half-tone worker, however, does not mind flatness, because the fine-etcher can readily correct this by re-etching.

With the increasingly good quality of present-day letterpress printing, it is possible to get impressions from blocks which could not have been printed at all a few years ago, and a 400-line screen block is no longer a matter of wonder, though it is certainly not often seen. Process workers and printers

seem too much afraid of fine rulings, and 200 lines is the present limit of their ambition. But my opinion is that the last word will not have been said in half-tone work until screens of 500 lines and more per inch are used, so that the effect of

Photo by]

WILLIAM GAMBLE,

[Curley Lewis.

A well-known authority in process engraving.

the screen will have entirely disappeared, and a result equivalent to the continuous tones of the photograph is obtained. The prevalent idea that blocks made with such fine rulings as 400 lines are impossible to print under ordinary conditions is quite erroneous. In several cases which have come under my own observation the blocks have been no more troublesome to print than those from a 175-line screen. I should like to see the experiment tried of using the 400-line screen for three-colour work. If I am not mistaken it would show a marvellous advance on present-day three-colour results.

Concurrent with this tendency towards the use of finer rulings is a strong revival of half-tones from coarse rulings for newspaper work. Screens of 50 to 85 lines are being used, and the results are astonishingly good. This is due no doubt to a more skilful handling of the screen than was given to it some years ago when half-tones for daily newspapers were tried and pronounced a failure. Another reason, perhaps, why the idea is more successful now is that the stereotyping and printing of daily newspapers has much improved. There can be no doubt that we shall see half-tones more and more extensively used in the daily Press in the immediate future. It is the ideal process for the rapid illustration of public events, as the directness with which the negative can be made from the photograph without the intermediate aid of an artist, and the quick etching which results from the shallowness of the half-tone plate, enables blocks to be made very rapidly.

I am inclined to think that more might be done in the way of making the half-tone negative from a transparency made by contact from the original negative instead of from a print

as now. Still more expeditious would be the plan of making a half-tone positive by working with a transparency camera. True, this would give a negative print on the zinc or copper-plate, but this could be converted into a positive by an easy process of reversal, such as is now often done for producing white lettering on black ground. Generally speaking, this consists in developing the lines or dots to clear zinc, then inking or flowing with a varnish all over, after which the ground is removed by a solvent which will not attack the varnish adhering to the previously bare metal. This leaves the ink lines or dots strong on the metal in the parts which had previously developed white. The gain by such a process would be that the newspaper photographer would bring in his plates or films, develop them, and even whilst wet place them in the transparency camera, to be copied as a half-tone positive. No time would thus be lost in drying the negative and making a print, and there would be, moreover, the gain which must always result from the elimination of intermediate processes.

This suggests to me that we might go a step further and do away with the process camera altogether for the sake of rapidity and directness, which is so essential for newspaper work. We can do this by adopting a process suggested so long ago as 1896 by my friend, Mr. J. A. C. Branfill, but which, so far as I know, has never come into use, though Mr. Branfill himself showed me some very good results. It will be easy to understand the arrangement of the apparatus by means of the following diagram:—

Fig. 1—A—the Arc Lamp. B—Condenser. C—Projecting Lens and Diaphragm. D—Ruled Screen. E—Separation. F—Positive or Negative. G—Sensitised Plate.

The light, condenser, and lens are contained in an ordinary enlarging lantern, and the only difference made from the usual arrangements for enlarging is to put a diaphragm with square aperture in the lens, the square being set at 45 deg. to the screen lines. The apparatus at the right-hand of the diagram is contained in a box-pattern pressure-frame. First, the ruled screen is placed in it; second, strips of cardboard to give separation equivalent to screen distance; third, a thin positive or negative; and fourth, the sensitised surface, which may be either a metal plate, photo-litho transfer paper, or carbon tissue. Of course, the light must be very powerful—in fact, nothing short of the electric arc, unless we use this method only for making the screen negative, which can be done on a process dry-plate.

The principle of this method is exactly the same as that of half-tone negative-making in the camera. The size of the stop, the distance of the lens from the sensitive plate, and the distance of the screen are governed by exactly the same rules, and may be found in the tables of screen distances published for the use of half-tone workers.

The object of the lantern and square diaphragm is to furnish a spot of light, so that every opening in the cross-line screen, each acting as a pinhole lens, may photograph it on to the sensitive surface, where it is developed as an opaque dot. An interesting fact in this connection is that if we increase the number of apertures in the diaphragm, or, in other words, the number of spots of light, we can, provided the spacing of the holes bears a suitable proportion to the spacing of the screen lines, reduce the exposure by one-half for two apertures, by one-third for three apertures, and so on. Of course, a limit

the number of apertures is the area of the lens surface, and if the apertures are made small the exposure is governed by the f value of each individual aperture.

Incidentally I may mention my belief that a process recently patented by Dr. E. Albert, of Munich, for producing half-tones for colour work without the aid of a camera is based on the same principle as Branfill's idea, plus the principle of multiple diaphragms.

This question of multiple diaphragms has really a very important bearing on the future of half-tone; and the only person I know of who has fully grasped the bearing of it is Mr. U. Ray, of Calcutta. He has elaborated it to a mathematical exactness, and it is not improbable that he will shortly publish a treatise on the subject. It is, of course, important, in order to get the maximum effect, that the screen distance should be set very accurately so that the images of each aperture in the multiple diaphragm should coincide on the sensitive surface.

Ray smooths the path of the operator in this respect by using a mechanical screen distance-indicator somewhat like a pantograph, which moves a pointer relatively to the opening and closing of the camera extension.

Another way of using the half-tone screen in conjunction with the enlarging lantern is to place it next the positive in the lantern slide-carrier of the lantern (Fig 2), but with such variation as is demanded by the conditions of screen discing, and to place a square aperture in the lens, then projecting the image in enlarged size on to the sensitive surface. This method is especially applicable to poster work—a field in which there is great scope for the half-tone process.

2.—A—the Arc Lamp. B—Condenser. C—Positive. D—Ruled Screen. E—Projecting Lens and Diaphragm. F—Sensitive Surface.

Another further method of producing posters is to place a cross-lined screen in front of a thin positive, and illuminate the latter by means of reflected light (Fig 3).

3.—AA—a Board Covered with White Paper. BB—Arc Lamps. CC—Positive. DD—Screen. E—Projecting Lens in Wall of Dark Room. FF—is the Sensitive Surface.

An enlarged image can then be projected into a dark room by means of a good camera lens. In this way enlarged wet-plate negatives up to 60 by 40 inches have been, to my knowledge, produced very satisfactorily, and from them most striking lithographic posters obtained. The method is substantially the process of gigantography, which was patented not long ago; but I fail to see how the validity of such a patent could be maintained, for if I mistake not this was just the way Meisenbach made his earliest half-tones, and many others have described similar processes.

Turning to another new phase of the half-tone process, I would remark that it might be supposed the question of the best angle for crossing the screen lines had been settled beyond controversy at the angle of 90 deg., with the lines laid at 45 deg. to the sides of the plate. But this shows how the half-tone worker can get into a rut, and keep in it, by accepting a thing because "everyone says so," or "everyone uses it." A loophole is left for an ingenious experimenter to step in and patent a process of ruling the screen with the lines crossing at 60 deg. (Fig. 4) showing one way of doing it:—

Fig. 4.

Fig. 5.

This idea was first described by Mr. U. Ray; but Mr. Arthur Schulze, of St. Petersburg, forestalled him by obtaining German and British patents on it last year. This screen actually gives a much smoother and more pleasing effect than the screen with 90 deg. crossing, as I can testify from results I have seen. It is a further advantage of this screen that multiple diaphragms work well with it. Part of Schulze's patent consists in the use of a diaphragm with three openings, which may be triangular, square, or round, disposed at the corners of an equilateral triangle (Fig. 5).

Ray claims that with such a screen, and with his method of using multiple diaphragms, it is possible to use only the one screen in one position for three-colour work, and yet not get any of the moiré patterning which usually results from superimposing the prints from three negatives taken with the screen lines at the same angle.

I think it will be gathered from the foregoing brief resumé of potential methods that by no means the last word has yet been said on the half-tone process, and that it has still greater possibilities than it has yet achieved. WILLIAM GAMBLE.

We have heard such a lot about radio-activity lately, says the "Daily Chronicle," that—some of us are getting rather muddled as to what it means. Several medical papers, for instance, on both sides of the Atlantic, imagine that radio-activity means the power of giving off rays. Therefore anything warmer than its surroundings is radio-active, not to mention a candle burning or either end of a telephone, or nearly everything else one can think of. This is no discovery. Radio-activity is the power of giving off certain material particles as the result of atomic evolution. It will take some time to remedy this confusion, however.

Colour Sensitometers.

THE reproduction of coloured objects correctly in hue and luminosity by means of three colours, being greatly hampered by the limitations of the photographic process itself, necessitates the greatest care being taken that the conditions throughout should, as far as possible, be in harmony with each other, other-

Photo by]

EDGAR SENIOR,

[Violette Cotton.

The well-known experimentalist in Lippmann Colour Photography.

wise differences in colour would be readily detected which in black and white would pass unnoticed. The three-colour process of colour photography is based on the theory that there are three spectrum colours which, when mixed in suitable proportions, will match every other spectrum colour, and consequently that of any coloured object; therefore if a colour record be obtained by analysis of all colours, into three simple spectrum colours, then by subsequent synthesis in these three simple colours, a reproduction to the eye of the sensations of all the original colours will be obtained. The three simple colours found to fulfil the required conditions the best are a red situate near the red lithium line, a green near the E line, and a blue-violet near the blue lithium line. These practically correspond to the colours of the glasses used by Ives in his kromskop, where the results are obtained by the mixing of coloured lights. When, however, the finished picture is to be obtained by the superposition of three coloured images, as in the case of transparencies for the lantern, or prints on paper, then we have it on the greatest authority that the colours should be complementary to these. In order to see what these colours are it is only necessary to project a fairly bright spec-

trum on a screen, and by means of three slits isolate three small portions, one in the red near C, another about the E line, and a third near G, and then alter the intensities of the three issuing

Fig. 2. I.

rays in such a manner that by their mixture white is produced. It is now only necessary to screen off from the mixture each ray in succession to obtain its true complementary. Thus, if the red light is screened off we get a peacock blue, in the case of the green a purple, while if the blue light be intercepted the complementary would be a yellow with a greenish tinge. These then

Fig. 2.—II.

appear to be the colours that should be adopted as the standard in three-colour printing. The photographic records, however, which would yield correct results with one method of synthesis

should do so equally well with the other. In order to ascertain when correct records have been obtained it is necessary to employ a suitable test object. If the spectrum be used for the purpose three negatives must be made in each of which photographic action is so distributed that it would be represented graphically

Fig. 2—III.

by curves, such as in Clerk Maxwell's or Sir William Abney's diagrams of colour—mixture curves of the spectrum, the light filters used in taking the negatives being modified until these conditions are fulfilled. Although theoretically the spectrum would be the best test object, in practice, when using plates

Fig. 2—IV.

rendered orthochromatic by means of dyes, we are troubled with bands or gaps of varying sensitiveness which result in an irregular rendering. And if plain plates are employed in which there is only a gradual fall of sensitiveness from blue to red, without gaps of insensitiveness, the length of exposure required for the green and red, operates against their general use. It,

therefore, appears that the spectrum is not a good test object for orthochromatic plates, and resort must be had to other means, and in that about to be described coloured glasses are used. The selection of the glasses is important, since their colours should be fairly representative of the principal colours of the spectrum.

The first thing to decide is what colours are to be used in the reproduction, and then to find what mixtures of these colours will match those of our glasses. Having done this, we are in a position to reproduce the colours of our test object in hue by means of three negatives from the data thus obtained. It now remains to do so in luminosity. To accomplish this the luminosity of the light coming through the glasses must be measured, and from this the comparative luminosity of the colours which when mixed go to form that of the glasses, obtained by multiplying the components by the respective factors. It now remains to reduce the luminosity of the different glasses to the standard of that of the lowest in each of the constituent colours,

Fig. 1.

when we obtain three sets of colours of modified luminosity which should give equal opacities behind a red, a green, and a blue screen respectively, when the screens are correctly adjusted to the plate, the screens being altered until this result is approximately obtained. A test object of this nature "which constitutes a sensitometer" can be used with any plate, and is directly derived from the colours fixed upon for reproduction, the only conditions being that light of the same nature as that used in making the measurements shall be employed in testing the screens.

The instrument designed for use, "the general appearance of which is shown in Fig. 1," consists of a frame carrying a sliding panel in front, into which are fixed the coloured glasses comprising the sensitometer, and these by a simple movement are able to be brought successively into position over photographically produced densities contained on a plate underneath, for the purpose of reducing their luminosities to the required degree in each case. When the apparatus is to be used the

sliding front is moved until the catch at the side falls into position at No. 1, when the conditions are such as are required for testing the red screen. A sensitive plate having been placed in the holder at the back, and a screen fixed in front of the glasses by means of a spring, the exposure is made. The sliding panel is then moved forward until the catch engages in No. 2 and a green screen substituted for the red one, and a second exposure made, and finally into No. 3 and a blue screen replacing the green. It will be thus seen that the same plate is employed throughout all the tests, and although the colour of the screens will differ with various brands of plates, the point to remember is that the same density, as near as possible, should be produced by development under all the squares, and the absorbing media must be altered until this is attained.

In Fig 2 is shown a series of four tests made upon the same

kind of plate, but with a different set of screens in each case, "the small letters indicating the colour of the glasses forming the sensitometer." It will be noticed how the results vary with the filters employed, those used in taking No. III. and IV. producing perhaps the best in practice. Correct screens having been found, they may be used for photographing the row of coloured glasses in order to see whether they can be reproduced in hue and luminosity by means of the three colours chosen, "the inner part of the instrument being removable for this purpose." In conclusion, we wish to say that no claim to originality is made in the instrument described (beyond whatever may attach to the particular form of the apparatus itself), the idea being simply carried out from the published suggestions of Sir William Abney, and based on the principles involved in his sensitometer for orthochromatic work.

E. SENIOR.

The London and Provincial Photographic Association.

NOTWITHSTANDING many stormy scenes, when the air has been thick with resignations, notwithstanding the general lack of interest in society work, probably caused by the keen struggle for existence of to-day rendering most men prone to seek rest at the end of the day, instead of spending an evening in strenuous discussion at a society meeting, the London and Provincial still

proportion of its members who take enough interest in their society and photography to come down to the meetings.

In a vast city like London, with its huge distances, its many counter-attractions, and the weary anxiety of its daily toil, it is hardly to be expected that meetings can be secured as large as provincial towns can offer, but for an average attendance the meetings of the London and Provincial compare very favourably with any London society, not excluding the "Royal," with its glamour of prestige and its respectability of age.

The reading of the committee and general minute books offers an instructive and amusing evening, and having spent a few hours in this way one cannot help being struck by the similarity of the proceedings in the youthful days with those of to-day, when the association has attained and passed its majority. One finds the same solemn business in committee, the same gentlemen, or their prototypes, inviting all and sundry to tread on the tails of their coats, what time other members are still, as did their forerunners, drawing the delusive red herring across the track. One finds that the vexed question of "Ladies' Nights" was as keenly discussed, supported, and condemned in days of yore as now, and that the very secretaries were from the beginning worried as to non-payment of subscriptions, and as to how to make the evenings more attractive. And we still have a member always ready to open a discussion on "Combined Toning and Fixing." But still the association goes on meeting regularly, despite the fears of hon. secretaries; the subscriptions are paid sooner or later, and evenings still seem attractive enough to keep up the average attendance.

One feels bound to acknowledge the help of those members whose names are to be found in the books of twenty years ago, who were then and are still of importance in photography, who, year in, year out, have attended the meetings in one unbroken sequence. Week after week they are there, ever ready to welcome and assist the new member, and by their loyal affection to the association they have helped to start, are still forwarding its aims and success.

A word to would-be members who have heard, and are scared, by terrible tales of the doings at the London and Provincial. I joined five years ago, a raw novice, and was taken in hand in the most kindly manner. Never a sneer at my inexperience, never a snarl at my "wanting to know"—always a friendly lead and a helpful explanation; and so it is to-day, unless you want to teach those who know better, and then your lot will not be a happy one. I advise everyone whose business or pleasure is

R. J. KINSON,

Hon. Sec. of the London and Provincial Photographic Association.

goes on its way rejoicing, with a sufficient balance in hand, with an ample roll-call, and, what is more important, with a goodly

photography, to join a society, and an established one like the London and Provincial, whose roll of members has included so many of the most revered names in photographic circles, and whose meetings are still as full of interest and vim as they were before many of the societies of to-day were born.

The London and Provincial is not an art association; it does not encourage trade demonstrations, and it is not very keen on lantern nights; so other societies' hon. secretaries will sympathise with their brother of the London and Provincial, who is expected to arrange a programme for 52 evenings in the year, with papers of a high order of merit, and whose only reserve is "Open Nights," which do not look attractive on the programme, but have made the association what it is. These are the evenings to see it at its best, for it is then that a seemingly simple, but in reality an artfully-planned query sets the table in a roar, *pro and con*, or an apparently innocent negative or print calls forth the heavy artillery, and the self-appointed official opposer

falls foul of the old guard with his experience of thirty years or more, and one's knowledge is enriched by the revealing of useful, but little-known formulæ, chemical, optical, and technical facts, all of which are hotly disputed up to the moment of closing, when the chairman's hammer puts an end to official discussion, and the combatants retire "round the corner" to fight it out or come to an amicable settlement.

And now, hearty congratulations to the BRITISH JOURNAL on reaching its jubilee. The warmest thanks are due to the Editors for the continued support they have accorded all societies. The London and Provincial certainly owes much of its success to the weekly report of its meetings, space for which the BRITISH JOURNAL rarely fails to allot. I trust the time when the London and Provincial's meetings cease to be of sufficient interest is as far distant as the day appears to be when the BRITISH JOURNAL OF PHOTOGRAPHY shall cease to be the "Times" of the photographic Press. R. J. KINDON.

Fifty Years' Reminiscences.

STORY! God bless you! I've none to tell you, Sir." Such were my first thoughts when I received the suggestion to give some of my recollections for half a century back for the Jubilee Number of the "B.J.P."; but, when I remembered that I was within three years of the jubilee of my own introduction to photographic practice, it occurred to me that, after all, I might have a story to tell sufficient to interest the present generation. I well remember my very first photographic experience. It was at a time when, if the pattern on a plaid necktie or the button-holes of a coat showed crisp and clear, attention was first concentrated upon them rather than on the features themselves, and the portrait praised or dispraised accordingly. I had seen my father collodionising plates, and, determined not to waste collodion, though I would practise coating a plate by pouring a pool of water on and off. The result can be imagined. But I did not decide all at once to take up photography in earnest. I suppose I was ambitious. I had taken several medals from South Kensington, was qualified under the "Department" to teach, and, further, was associated with a band of earnest workers with the brush—Luke Fildes, R.A., Harry Woods, R.A., E. Brentnall, members of the Old Water Colour Society, and Warrington Wood, the sculptor, were all fellow students with me at the Art School; but Fate took the matter in hand and I settled down to what, once, was a very lucrative profession. Present-day photographers have little idea of the work of what they would consider such palmy days—no proofs, no retouching. You made your exposure, took a few seconds to develop, and, after fixing, brought the plate out to your sitter, who always was pleased if the positive was clearly taken and properly exposed. It was then dried and varnished at the fire, put in a case and delivered "while you wait"—and—paid for! Or, perhaps, your sitter preferred it "coloured"—ten and six or a guinea, or more extra, according to size, etc., for a few minutes working up with powder colour! Then the case, rarely less than half a guinea, and often much more. In those days—nearly fifty years ago—the name of Mander for cases was supreme; other workers have come and gone, but Manders are still with us, still noted for the highest class of leather cases. When the question of permanency of photographs attracts such attention it is worthy of note that old glass positives of the very earliest period are, when properly varnished, as good this day as when first sent out. I had one, only a short time ago, to re-frame, and I knew the photographer's

style at a glance—Lee, of Liverpool. He used to take his positives on colourless patent plate-glass, and mount them, glass side out, so as to present a non-reversed image. He generally used claret coloured velvet to back them up with. His portraits were unsurpassed—rarely equalled. Their only defect was the liability of the colourless glass to "sweat." After collodion positives had enjoyed popularity for some time a method of whitening them with bichloride of mercury was brought out as a secret process, with a big fee for disclosure of the method of production; process mongers had a great run

G. WATMOUGH WEBSTER, F.I.C., F.C.S.

then. These whitened positives were very effective, and the recipe for compounding the developer was a marvellous con-

section. The term Alabastrine was invented for them. But, as a matter of fact, the whole secret—and to this day this is not well known—lay in the varnish. A spirit varnish was fatal; the beautiful white image, the moment the varnish went on, was converted into a wretched bluey white, which no one would look at. All that was needed was a benzol varnish, which did not alter the state of aggregation of the silver particles comprising the image. My first professional experience was out of doors, a carpet being laid and a background erected, while overhead was an awning to prevent heavy shadows. But photographic portrait taking was looking up, and more pretentious surroundings were expected.

About this time I designed my first studio—8ft. wide and 20ft. long! My father, with whom I was then working, had as friends and correspondents two men whose names will always be associated with the early days of photography and photographic literature—Henry Greenwood and Alexander Forrest, the latter always a most enthusiastic and skilled photographer and still among us, the doyen of photographic experimenters and workers. He will also be remembered by the older generation by the "vignetting glasses" which he introduced and sold by thousands, and by the fluted glass dippers that he introduced, and which were used by all photographers. I am proud to remember that my father devised them and conveyed the idea to Mr. Forrest, whose firm at once took to the invention and produced and sold the dippers in large quantities.

Photographers of a dozen or two years' standing will perhaps be incredulous when I tell them that in the very early days of the art the method of making vignettes was quite a secret. The process and not the man was looked upon as the factor. I can recall a curious incident in this connection. I was busy in the studio when a man of the tout tribe walked in. "Young man," he said, "I'll teach you the fanatt bizniz for a sov." It was some little time before it dawned upon me that he wished to impart the secret of making vignettes!

Those who are conversant with the history of the beginnings of photographic practice will remember that negatives and paper prints therefrom were exceptional productions in a studio. The commonest plan was to take a "positive" and "convert" it—that is to say, whiten with bichloride and blacken with yellow "hydrosulphuret of ammonia," as the liquid was then called. I very soon came to the conclusion that a real negative developed as such at one operation was the proper thing, and, as usual, I set to work to experiment. When we took glass positives the great point was to wash the developer off at the right moment with as much despatch as possible. This at our studio was done by dashing the plate into a large trough of water. When I made my first pyro developed negative I naturally adopted the same method of washing. The trough was in a very dark corner. I dashed my plate in, waved it well to and fro, and brought it into the light to examine. A piece of plain glass only met my gaze! It took some little time to become familiarised with the pleasant little game films used to play when treated with acid pyro. But eventually I adopted the plan of roughening the margin of all the glasses—nothing but patent plate would be looked at then—before coating with celluloid.

When I took my second negative—one had to learn everything by experience at that time; there were no teachers—I could not, as I imagined, get it to "fix" properly. Eventually I discovered that what I imagined to be undissolved iodide was the prized "bloom" which characterised some of the early negatives with iodised collodion. Some time afterwards the method of albumenising glass to prevent the film slipping was introduced, but I never adopted it. I was loath to introduce organic matter into the silver bath which was ready enough to go "wrong" without provocation at any time without this added danger.

As years passed on a new dawn broke—first a tiny ray of light

that eventually broadened and spread, and finally became an all-pervading brilliant light. A little paragraph appeared in the JOURNAL to the effect that a new fashion had made its appearance in Paris. Instead of leaving the usual "pasteboard" fashionable people sent in as their visiting card a tiny full length portrait of themselves, and it was hoped that the fashion might be introduced in this country, and so add slightly to the photographer's income. The *carte de visite*—Anglicised, visiting card—was introduced. It seized the public fancy, it became the rage, and soon was rampant. Modern photography was created as by an enchanter's wand. High and low, rich and poor, all flocked to the photographers' studios, and such a harvest of profit was reaped as to lead to wealth almost "beyond the dreams of avarice." Every household had its album and the first thing a visitor was asked was to present one of his *cartes de visite*—the expression had been at once adopted *en bloc*, though its ordinary signification was quickly lost. Those whose experience of photographic practice is confined to the last ten or twenty years can have no conception of the absolute furor that seized the whole population of this country, indeed, of all Europe. Everyone, whether he was anyone or not, was photographed. From early in the morning to the dusk of the evening reception rooms were packed with sitters waiting their turn, studios reeked with the odour of collodion and acetic acid, orders were months in arrears, salaries ruled high, money was being coined. In the more pretentious studios eight or twelve exposures were made on a plate and printed in sheets; no retouching; full lengths the rule, vignettes the rare exception. A guinea for six *cartes* was common. A guinea a dozen was looked upon as a "cutting price." In Westbourne Grove Camille Silvy—to mention one prominent name—in two or three years acquired a huge fortune from *cartes de visite* at two or three guineas a dozen. Over a hundred sitters every day was not uncommon. There was, as I say, a positive furor. Then came the usual reaction. New studios were started, prices were cut, till the unheard of price of half a guinea a dozen was reached, and photography, in a sense, fell from its high estate, to be galvanised into popularity once more by the introduction and steadily increasing adoption of the "Cabinet" portrait, combined with more artistic methods of posing.

As my name has been so often invoked with regard to studio construction, I will just mention that at the time I am treating of I designed and superintended the erection of another studio, in Liverpool, where I contemplated commencing a new business, though I did not carry out my intentions. It would be about the period I am writing of that the now world-famous "B.J.P." adopted its present garb. Mr. Greenwood first called it the "Photographic Journal," and in its first issue under that name it was stated in the introductory words that the new name had met with general approval, one subscriber only having objected to it. This objector was my father, and the validity of his protest was shown by the ultimate adoption of a title which is now known over the whole civilised world.

Shortly before the advent of the *carte de visite* a great amount of excitement and controversy was aroused over the matter of collodion and its manufacture. A great many photographers made their own collodion. They bought pyroxyline ready made, dissolved it, added the requisite haloids, and thought they knew all about it. A prize—the first example, I think, of photographic competition—was offered for the best collodion competing, a condition being that the mode of manufacture of the winning sample was to be published. Mr. Hardwick was the only competitor, and he was awarded the prize for a collodion the manufacture of which in all stages was described in a masterly treatise he wrote, a monument of patient skill and investigation. He placed the manufacture of pyroxyline on an almost mathematical basis. The conclusions he arrived at have never been upset, nor the results excelled. The manufacture of gun cotton, as it was usually,

ough improperly, termed, is a very delicate operation, but when once entered upon is absolutely fascinating. For a period about two years I spent almost all my spare time in making various kinds and testing them after dissolving into collodion. Eventually I settled upon iodide and bromide of cadmium, which gave a colourless collodion, and I worked it with a neutral to test paper, a most difficult combination, but making the highest sensitiveness to be obtained.

"When the 'carte' was first introduced almost every print out was toned in the old hypo and gold toning and fixing bath. Pure whites were rarely, if ever, obtained, and the prints were almost all very fugitive. Messrs. Davinne and Girard published the results of their epoch-making investigations of the causes of fakings, and the alkaline gold tonings began to be talked about. The profession were very loath to adopt, but the logic of facts was too strong; the work could be got through more quickly and pure whites were the rule. The great fault was mealy prints, and the prints were mealy. I set to work experimenting on them and the various papers on the market. M. L'Abbe Laborde published the acetate of soda formula. This was tested in my laboratory and found to bear the palm. I adopted it, and have used it ever since. I believe an alkaline gold bath equals it for beauty of results, combined with keeping properties. I think Mayall was about the last photographer of eminence to give up the combined bath, and when it is remembered that Marion's (the great publishers of celebrities in those days) gave him an order for a hundred thousand Royalty photographs at once it will be readily imagined how handicapped he would be with the combined bath. In those days Disderi, of Paris, was a name to conjure with, and I mention it here to call attention to the fact that he was perhaps, the first in this country to use the process of "dry collodion." I have seen tens of thousands of prints at the place he then had at Brompton, all ready coated with gum at the black waiting to be mounted. That must be nearly thirty years ago. I might mention that at the time there was a great demand for cartes of the Empress Eugénie, and, to meet it, Disderi printed transparencies on collodion, and transferred them to enamelled paper, thus multiplying the negative's capacity a hundredfold. There was no fomite nor "gaslight" paper in those days.

It will, I think, be interesting to describe a novel use to which I put a camera in 1861. It may be remembered that Crookes discovered the metal thallium in that year, being aided by Bunsen and Kirchhoff's recent invention of the spectroscope. I had virtually the run of Messrs. Roberts, Dale, and Co.'s large laboratories at Manchester and Latchford, Mr. John Dale, F.R.S., being an intimate personal friend. We were fired with the ambition to extract some thallium from its first discovered source—flue-dust—and to test our product with a spectroscope, though there was none on the market. We, however, rigged up a camera, using the lens for a collimator, and an old tint glass prism fixed in the place of the ground glass. A small hand telescope was packed up to receive the refracted rays. We extracted our thallium, and conclusively proved the reality of our product by the presence of the characteristic green line in the spectrum. Just about the same time I had a golden opportunity of copying a wonderful daguerrotype—no less than a portrait of Dalton, the inventor of the atomic theory. It was a most cherished possession of Mr. Dale, senior, as no other was known to be in existence except a duplicate in the possession of Dancer, the optician, of micro-photographic fame. His micro slides of the Lord's Prayer, the size of a small pin-head, had an immense run.

To return to our cartes. Some time after their introduction, and when "vignettes" became the vogue, retouching began to be talked about. Reutlinger, of Paris, published some beautiful heads from neatly-retouched negatives. People used to rave about them, and "the clear air of Paris" that enabled

such results to be obtained; not a word about retouching was heard. But in this country Edge, of Preston and Llandudno, had been silently working on the same lines. All his negatives were retouched, and not with black-lead pencil as now, but with Indian ink. At a very early period I practised retouching till I was fairly expert, and then sent out all my portraits from retouched negatives. I think I was the second in this country to adopt it with every negative, Edge being the first, though I believe Claudet occasionally employed it at that time. Retouching was then a secret art, and its exponents usually worked with locked doors to prevent their methods from being discovered. They obtained fabulous salaries. This was a notable time in other respects; Dallmeyer's newly-designed 2 B. lens for studio work was to be seen in every studio, and Ross's "Actinic Doublet" held the market for outdoor work till the famous Rapid Rectilinear of Dallmeyer and the aplanatic doublet of Steinheil changed their methods and opened out new possibilities, while Ross's symmetricals later on revolutionised every photographer's kit. The old studio I have referred to was far too small for the new photography, so I designed a fresh one on a larger scale, and adopted a system of blinds, which I still find superior to any other I have seen, while being simple and economical; it merely consists of curtains of some dark fabric suspended from pairs of wire stretched taut by a stretching-screw that I had to devise, but one similar to which can now be purchased at any ironmonger's for stretching wire fencing.

About this time I was intimate with that most genial of men, the late Thomas Ross, and most interesting it was to learn first-hand of some of the very earliest experiences of lens-making in connection with photography. There were two famous lens-makers in the world, Andrew Ross and Voigtlander, the latter having been the first maker of a lens which still holds the field for critical sharpness, over a limited area—the Petzval combination, generally known as "the portrait lens."

My recollections have now reached the end of the sixth decade of last century, which marked an epoch in my life's work. About the year 1869 I first had the honour of becoming a contributor to the pages of the "B.J.P.," which started a friendship with Traill Taylor that continued unbroken to the time of his death. I also commenced business in Chester. Of course I built another new studio, a description of which, from the pen of that well-known writer, the late Thos. Sutton, whose acquaintance with photographic optics and processes was profound, quickly found its way into these pages. I had not been long established before my connection with Hawarden and Mr. Gladstone began, and when an interesting incident occurred which I cannot remember if I have ever recorded before or not. It will bear repetition in any case. I had been executing a special commission at Hawarden for Mrs. Gladstone, and I asked her if she would persuade Mr. Gladstone to sit for me. While she was absent on this mission I prepared my plate "on spec"—wet-collodion days. A message was brought to me that Mr. Gladstone would sit; but only on condition that the portrait was published at such a price that it could be retailed at sixpence, as he considered that one shilling, the then price of cartes of public characters, was far too high. No argument would move him. Anxious for the honour of a sitting from him, I unwisely consented to his restrictions. All the time of the discussion my poor wet-plate was getting dried up in the dark slide, and before he actually sat he wrote out an agreement to the above effect for me to sign! I got my negative taken, produced a large number (in Woodburytype), offered them to the publishers (Marion's) and sold—none! No one would touch a sixpenny carte, and it damned me with the trade for trying to cut prices—they would take nothing from me. I wrote to Mr. Gladstone explaining this result of carrying out his wishes, and received a communication—on a post-card, of course—withdrawing his stipulation about price. Too

late for me. Many a time since then was I privileged to have sittings from him, and my last connection with Hawarden and Mr. Gladstone was to make photographic copies of his will after he died. I gave up the negatives, and they were never published, though they would have possessed the highest interest. The will was written in his well-known handwriting in the pages of a little penny memorandum book.

Saving the instrumental improvements I have recorded, which also were associated with the first popular folding bellows camera—the Kinnear—photographic methods had undergone little change after the introduction of the alkaline gold toning bath. But now an invention was made which initiated a change that revolutionised photography, and made it a science of world-wide importance, and was the first step in the decadence of professional photography to the individual. I refer to the improvement in the gelatine emulsion process by an amateur—Bennett—who conferred on it a rapidity many times that of wet colodion. Everyone was at first incredulous; but the invention was of too vast importance to be allowed to lie fallow, and the germs of the present immense trade in dry-plates were sown.

No longer was skill needed to be able to take a photograph; very sensitive plates were quickly purchasable ready made; the price first advertised was so much per square inch of plate, and afterwards 7s. 6d. a dozen for half-plates, and so on. My experiences in studio-building continued; I had built a second studio at my Chester premises, and then had to move. This involved, as every photographer who has to flit knows to his cost, the erection of still another studio, the one I am still occupying, and which is furnished with blinds of the pattern I devised years before as just described.

There will naturally be less interest in my experiences since then, as they will come into line with many contemporary workers, there being few left of those who started contemporaneously with myself. I have had a large measure of fortune in having sittings from eminent people, from the very highest to the very lowest. I well remember the first time His Majesty Edward the Seventh, then Prince of Wales, sat for me. There was, and is, a popular impression that a commoner may not speak direct to Royalty, but must do it through a third person. I shared that belief (the occasion being a group with His Royal Highness and a score or two of titled sitters). I asked the Duchess of Westminster how I must proceed. "Oh, go and speak to him like anybody else," her Grace graciously replied. I got my group all right, but found the Prince was "not to be had" otherwise. The moment the exposure was made he turned his back to the camera—no unauthorised snap-shooting for His Royal Highness! The most interesting photograph of him I possess is perhaps where he appears in a view of the party as travelling in a small railway car on the Duke of Westminster's private railway (which runs over part of his estate in Cheshire) en route for Hawarden Castle, where I had the honour of taking a group which is now almost historical—the Prince and Princess of Wales and Mr. and Mrs. Gladstone. On this occasion Mr. Gladstone seemed actually nervous lest he should seem to be pressing too near Her Royal Highness. I could not get him in a suitable pose till I actually pulled him into position by the lapel of his coat! One of the newspapers, describing the photographing, had the audacity to say of me that they should think the Prince of Wales had never been so "bossed" in all his life! The difficulty of this kind of photographing is that, usually, one has about half a minute of time allowed for the work—no arranging or posing, no focusing. You plant the camera and focus an imaginary sitter where you hope your big gun will come. When he does come you click your shutter, and the procession files away.

The most trying subject I ever had was, perhaps, when I took a negative of Gladstone and Li Hung Chang. I was wait-

ing all day—by permission—the august Chinese having, I believe, overslept himself and missed his train, hence arriving very late. His secretary told me just before lunch there would not be a possible opportunity of taking a photograph; but I held on secure of the good offices of Mrs. Drew, who has always been kindness itself to me. At the close of the afternoon I was rewarded by being able to take a 12-10 for what was one of a very well-known picture.

I had an amusing experience at Hawarden on another occasion. The representative of a leading monthly illustrated magazine asked me to go with him to photograph some special collection of signatures. After we had been in the Castle some time he said: "Mr. Webster, I am going to be taken with Mr. Gladstone turning over the leaves of that book." "I don't think you are," I replied. "Well, you'll see; I suppose you have everything ready?" "Oh, yes." Shortly appeared Mr. Gladstone on the scene. "Oh, Mrs. Gladstone, I thought Mr. Gladstone would just give me a minute to go over the book and show me any specially interesting signatures it would facilitate my work very much," said Mr. —. "Oh, we can do that quite as well as Mr. Gladstone," she replied. First check. Then Mr. Herbert Gladstone came in. "Oh, Mr. Herbert, I thought if Mr. Gladstone," etc. "Would not that be rather invidious?" said Mr. Herbert, and passed on. Second check. Finally, Mrs. Drew appeared. The same old tale. "Oh, Mrs. Drew, I thought if Mr. Gladstone," etc. Mrs. Drew burst into a musical laugh. "Mr. —, you do not know what you are asking; Mr. Gladstone has been looking forward all his life to the time when he should be able to devote himself entirely to his favourite literary work, and every half-hour of his time is mapped out for years to come. You really do not know what you are asking." Checkmate.

I am getting to the end of my egoistic utterances, for it is no use recording any of my doings of late years, which are mainly such as may fall to the lot of any professional. But I may add that I built still another studio at a watering-place on the Dee estuary, West Kirby, and was able to have one which, in the middle of summer, though thoroughly well illuminating the sitters, is perhaps the coolest room in the premises. I commend its design to all intending studio-builders. It has a high-pitched roof, with an extra ridge-piece, still further increasing the apparent pitch, with the result that at no time can the sun ever throw its beams into the room so as to cause it to become close or sultry.

Now I have, in carrying out the editorially-expressed wishes strung this bundle of recollections together, I begin to be afraid that, after all, any possible reader will think that my peroration should coincide with my exordium: "Story? God bless you, I've none to tell, sir!"

G. WATMOUGH WEBSTER, F.C.S., F.R.P.S.

"NEVER take a house on the strength of a photograph," is the warning cry of "Duped" in a recent number of "Tit-Bits." One photograph showed the front of an ideal country house long, two-storied, overgrown with roses and creepers, with a drive and all that kind of thing; and the other pictured an extensive and beautiful garden, with a spreading orchard at the back—acres of it, to all appearance. Well, sir, this house of delight was in North Wales, and I had no time to go so far to inspect it, and as the terms were reasonable I closed with the offer at once. I am in that house now—and I wish I was out of it. Can the camera lie? Sir, it can—it can beat Munchausen. The house is really a small and most inconvenient cottage, not half so big as pictured, the garden so small that you could scarcely swing a cat round in it, and there are just thirty trees in those acres of orchard. The photograph had been taken with a wide-angle lens, which magnified everything beyond recognition. No more photographs for me!"

Photographic Fallacies.

NE of my living ancestors tells of the troops marching to join the Duke of Wellington at Waterloo, and in the brief space of that one life photography has had its genesis and reached its present position as an important handmaid to the arts and sciences. And in photography as in all else the truth of yester-

JAMES A. SINCLAIR, F.R.P.S.,
Three times medallist at the R.P.S. Exhibition.

day becomes but a fallacy to-day. The increase of knowledge causes us to formulate new theories to fit in with our facts.

The Editor asks me to be retrospective and educative. But others can be retrospective better than I. My old friend Mr. Forrest, of Liverpool, remembers the birth of the *BRITISH JOURNAL OF PHOTOGRAPHY*, and, if he has yet strength, can tell of photography from its inception. I am a comparatively new sightseer through the photographic kaleidoscope. In this article, therefore, I think it well to be prospective rather than retrospective, and to deal with details rather than the whole.

When I started photography the hand camera was just beginning to attract attention, and so I may consider myself as contemporary with it. At first looked upon as a toy, it is now rapidly being recognised as the most valuable instrument we have for recording the life of our time. Its rapid development has done more for photography than all the years that preceded it, and it is daily breaking down many of the cherished theories of the old photographers embued with the superstition that it is only a plaything. But this "old school" still have the speaker's eye, or, in other words, they are energetic writers for the Press, where they perpetuate their desired beliefs, while the "new school" are content to smile and work rather than write. Let us examine a few of the statements which, in one garb or another, are being constantly served up for our delectation.

"That the Mental State Attending the Use of a Tripod Camera Conduces to Photographic Efficiency."—The tripod man is usually uncommonly proud of his prowess and achievements. His mental state is akin to that of the early riser, and because he has the strength of body and stubbornness of mind to do something distinctly disagreeable he feels that he and his kind are the elect and salt of the photographic earth. His perspiring exertions may bring their reward, but do not give rise to the humility of spirit we might reasonably expect. The hand-camera men are regarded with his pitying eye, while he lords the earth with his case of care. The demands on his physical nature seem to obscure his intellectual one, for when we try to lead him into more pleasant paths he repeats the fallacy which he has read.

"That the Tripod Camera is Better than the Hand Camera for Serious Pictorial Work."—This statement is repeated by the tripod man in season and out of season, and the delusion is comforting to him. He might with equal reason inform us that coal was better than bread or land better than water. But really he means more than he says, and infers that pictorial work is only possible with a tripod camera. He shuts his eyes to the trend of modern work, and while he talks and writes the hand camera dethrones him from his position. When constructed as the highest class instruments are constructed the hand camera does nearly all that stand cameras will, and also much more, and work of greater moment. It records the actual life of the race with greater ease and efficiency than the tripod camera, and if it is handled with prescient decision I conceive the results will be as pictorial as those produced by the more unwieldy instrument. "We needs must love the highest when we see it," and as I believe the hand camera is the best, I must confess it is good enough for me. Other instruments fail because they are slow in action. To illustrate this I must be pardoned if I relate one or two incidents in my own experience. While walking with two friends in Milan a few years ago they commented on my having made very few exposures. I explained that I had not seen any suitable subjects, to which they suggested I was hypercritical. Just then I caught sight of some scavengers approaching. "Now," said I, "here is a subject which I will send to the exhibition." I had noticed a whitewashed wall a little way back which the scavengers must pass. Rapidly adjusting my focus and setting my shutter, I ran to position, and made the exposure as they went by. The result was duly shown on the walls of the New Gallery, and some may remember this in the R.P.S. loan collection at the same gallery last autumn. Another photograph in the same collection—"Water-carriers, Toledo"—was taken under quite different conditions. The Moorish archway which forms the background had appealed to me because of the beauty of its lines. Here was a perfect setting if I could get suitable figures. I adjusted the rising front on my camera, set the shutter, lit my pipe, and waited. And I waited an hour before I found a jewel for my setting. Then the water-carriers appeared, the camera was raised, and the shutter released at the psychological moment. Here, again, a stand camera would have been useless; the figures would have observed it and looked disastrously conscious, even if the Toledo boys had not stoned both me and it long before the water-carriers appeared.

"That Slow Plates are Better than Fast Ones."—This archaic delusion is constantly being fostered and repeated by writers in the photographic Press, probably because the majority of writers do not work and the majority of workers do not write. In the old days, before the advent of hand cameras, telegraphs, and telephones, people were more leisurely, if not more lethargic, and had not the acuteness to judge rapid exposures correctly, conse-

quently speed was a positive drawback. Taking advantage of the weakness of humanity, plate-makers who could not make rapid plates with certainty, and even now get much wastage in the process, insisted on the merits of the "ordinary" brand. Yet, with all their insisting, they have been constantly experimenting in secret how to obtain speed with certainty.

The old preacher wrote: "The race is not to the swift or to the strong," but we live in other times, and I agree with Mr. Robinson. You may remember the lines:—

"John B. Robinson, he
Said they don't know everything
Down in Judæ."

To-day the race is to the swift, and if he is strong so much the better for him. We live in the "age of speed," the best age the world has seen. We must be thankful in a large measure to the importunities of the hand-camera worker for the speed of plates. The best makes of rapid plates are incomparably superior to slow ones for most classes of work. For general photography, portraiture, architecture, or landscape I prefer the fastest plate I can get. Such plates reduce harsh contrasts and give better shadow gradation. The slow plate has its uses in the studios of the process worker and technical photographer, but are not wanted anywhere else. If asked if I am satisfied with the speed obtained to-day I answer "No." I am nowhere near the realm of content. When I can photograph the interior of Westminster

Abbey in a fraction of a second with *f* 16 stop I shall begin to feel satisfaction. To such times I look forward.

"That Photographers are not Sun Worshipers, and Love Darkness Better than Light."—This delusion is very common amongst those who gain their knowledge of photography through visiting exhibitions and looking at the illustrated photographic Press, and I admit there seems good reason for their error.

With one accord the Brahmins of the art seem to cry aloud: "O Helios! banish thy light from us, or we perish, and our art is no more." And even if Helios hears not they show by their works that any light, twilight, moonlight, starlight, or no light is loved more than sunlight. These high-priests of the art are like troglodytes, whose eyes will not stand the glare of the sun. Each says, with Guinevere:

" . . . I could not breathe in that fine air
That pure severity of perfect light."

But the common people, who form the real stronghold of photography, with a saner mind and broader outlook, welcome the light, and prefer one dewdrop glistening in the sun to all the fogs of a November day. For my part, I think we shall do better by trying to render the most beautiful things beautifully than by showing our beautiful things in an unbeautifully clever way.

THE BRITISH JOURNAL OF PHOTOGRAPHY has in the past been a champion for pure, virile photography, and will, I hope, maintain its record for other jubilees to come.

JAMES A. SINCLAIR.

Detached Thoughts.

IT is discouraging to the professional photographer, when in his aspiring moods, to reflect on the association of the British nation with beef and beer. Beef and beer are such matter-of-fact things, and through them, I suppose, "fact" has wormed itself into the soul of the people. They are quite good enough things in their way, but produce so stolid a result that the photographer who wishes to give the people of his best too frequently finds himself obliged to abandon his hopes in despair.

In May, 1897, Mr. Harold Baker read a paper before the Royal Photographic Society in which he said, "There is but little encouragement of pictorial effect, and one lady somewhat bitterly complained that her portrait was like a picture, and not like a photograph." This leads me to ask, "What is a photograph?" I do not propose to answer the question myself; but I know what the public means by a photograph. It is something clear and sharp and shiny—also cheap. None of these excellencies concerns photography except by common repute handed down to us by our grandmothers, and received by us implicitly. Once upon a time they were, except cheapness, the media of photography, but have long ceased to be so with a process which has shown itself to possess an undreamt-of potential. Photography has been, and is, a constantly advancing and expanding art, yet one to which, at the end of only some fifty years, men would apply the *closure* and say, "Thus far and no further." A portrait in gum-bichromate would draw from them the rebuke, "You must be loyal to the medium of your craft." In these still experimental and developing days of photography such a remark is merely a parrot cry. We must, indeed, be mightily well satisfied with ourselves if we believe that we now know all about it, that we feel ourselves qualified to say, "Photography is so and so, and to-morrow, and next day, and next year it will be the same." We do not know its medium in its completeness, we do not know its limits. We revile a new departure to-day and bless it to-morrow. A science makes far

vaster and more rapid strides than does an art; as a science—a recorder—photography's limits may now, probably, be mathematically determinable; as an art, who can say that it has yet attained its fullest and best means of expression? It is in this line, the departure from the ordinary, that there is money to be made in the studio. It would, indeed, be a very real help to all of us if it could be settled—not stated, but settled—what it is that constitutes the medium of photography. We should then know when a photograph is a photograph and when it is not. It would settle many vexed questions, and might decide the fate of either the Royal or the Salon. Was Mr. Baker disloyal to his craft when he made a picture which was not like a photograph? Was Mr. Crooke disloyal when he made photography give him the qualities and richness of engraving? In a paper (it seems to be dead now, and I won't disturb its ashes by turning it up) read before the Royal Photographic Society about three years ago, some topics cognate to this were alluded to, and though no names were mentioned, we were given to understand what "purblind fatuist" meant. Was Mr. Willis a "P.F." when he introduced platinotype? Yet platinotype was denounced as photography imitating engraving. Photographers made duplicate prints on platinotype and albumen and compared them together for detail, then one of the characteristics of the process. And in like manner, now, with gum-bichromate. The people who denounced platinotype and have lived to extol it now in the same way denounce gum. These departures from the orthodox, from the recognised media, have not outraged photography, but have added to it and enriched it. Use them! Picture photography is an open field to those professional photographers who have the clients to appreciate it. Don't sneer. This only cuts out the cut-price, the Sunday, and the beach photographer. A professional man whom I know made some portraits of a sitter. One of them was selected as being artistically lighted. "Yes," said the photographer, "it is the best; but such as that will

ever bring me a single order." Now, here is the point. That man was wrong. The more educated of the public, a large and paying class, will rise in a quite unexpected way to anything above the style of the ordinary studio portrait. To my personal knowledge, based on inquiries which are made of me pretty frequently, there is a class of people keenly on the look-out for a pictorial portrait. The photographer just referred to has had reason since to pleasingly repent of his pessimism, and will have more reason still in the future. My professional brother may not care to take a hint from me—an amateur. His experience is infinite compared with mine, and infinitely sadder, too, in knowledge of human nature. But all human nature is not based on beef and beer. I humbly suggest to him to discard all cut and dried notions of what photography is, and to let himself go, and by lighting, focussing, and even, if it be not too wild all at once, gum-bichromate, place before the better-class sitter something which, whatever the process may be, is, by arrangement and lighting, a picture. There is reputation and money in it. In practice, I would say expose two plates, and consider them as speculative, on any sitter who looks likely to rise to the occasion, and make them as pictorial as possible. With proofs done in the usual way of business submit one of these, and, if done in gum, at two or three times the price of the others.

I beg to add some tangible recommendations written several years ago for my benefit by Mr. Harold Baker. "Some of the qualities that distinguish a 'pictorial portrait' from the usual thing are, (a) it must be a good likeness, not retouched out of all resemblance to human flesh and blood; (b) the effect should be broad, not broken up into spots of light and dark; (c) the pose must be easy and natural; and (d) there must be no apparent striving after effect, the art of the pose and lighting must conceal itself."

When I speak of art and artistic lighting, I wish it to be understood that the words are not used in any inflated or undesirable sense. If the reader likes to substitute for these the word "pictorial," the definition preferred by Mr. Baker, it will answer my purpose just as well.

Since the above "Thought" was sent to the press, I have received my copy of this journal of Friday last, and am interested to find in this, the organ of the profession, support of the views which I have ventured to put forward. "The public have come to insist on a vastly higher standard of artistic quality, and at the same time have learnt to be willing to pay adequately for good work" (p. 458). "A painting (let us substitute photograph) might be an admirable portrait and a house might be conveniently built, and yet both lack the magic touch of art of which Browning said: 'The little more, how much it is; the little less, what worlds away!'" (p. 461). "The object of a portrait painter" (photographer) "was to scrutinise the character of his sitter" (p. 462). This last is exactly that to which American photographers appear to have been devoting themselves for months past over Mr. Snowden Ward, of which, as G. P. R. James used to say, more anon. The "plain man" (p. 462), is the beef and beer man. He prefers a likeness retouched to the texture of lard; we have nothing here to do with him; he does not want "the little more," and he does not want "character"; the photographer will divine that as soon as the man walks into his studio. But there is a class, larger than most photographers appear to be aware of, which is desirous to have and willing to pay adequately for artistic work. It must, however, be borne in mind that artistic or pictorial portraiture is not arrived at by the royal road of unusual or grotesque lighting, by cutting slices off the head, by cramming the portrait into a corner, or by slabs of white and black. Any of these may be admirable and right in certain circumstances, but none of them is gospel in itself. On p. 447 of the JOURNAL are these valuable words:—"There are certain laws of harmony and composition in the making of a picture,

as there are in the scoring of an overture; and if we outrage them, our work, although it may excite an ephemeral notoriety by reason of its eccentricity, will not last. Those who have made a name in the field of art have done so by hard study of the principles upon which art work is based, and photographers cannot do better than follow their lead."

This, then, fitly concludes my case. Its moral is that we have never done learning, and may never rest on our oars, either in abstract learning or in the concrete form that that learning takes when the principles it has inculcated are embodied in the form of a portrait. And when all this labour has been gone through, when we can do and have done our best, what does the plain man say? I have alluded to a photographer who produced a pictorial portrait of which he said despondingly that it would never bring in any orders. As pointed out, he was mistaken. The "plain man" then had a word. He had known that sitter all his life, and when the

W. R. BLAND.

One of our leading pictorial photographers and judges.

portrait, which, to others, was an excellent, and speaking likeness, was shown to him with pride, he said, "Well! I should never have known it was you." But I am not suggesting to the photographer that he should offer this thing to a soul of beef and beer.

Technique is a real stumbling block. It is, to change the metaphor, the rock upon which good work is based, it is the rock on which good work is wrecked. Let us refer again to the JOURNAL, p. 447. A man objects to a portrait of his wife on the ground that it doesn't resemble her a particle. "No," agrees the photographer; "but, my dear sir, the technique, the technique." There is wheat among this chaff. We all go wrong on technique, because it has become a fetish with us and we worship it as a god. We confound technique with the technical methods of photography—that is, we consider it to mean sharp focus, detail, bloom, sparkle, and the rest. Let us obtain these properties and we ask for no more. The work is photographically perfect, and what more than that can anyone

want? A great deal more. Mind, I do not decry these things. I look on the training that must be gone through to ensure their acquirement, when desirable, as a necessity, just as I look on education as a necessity for the child and on the practice of scales for the musician. Some writers despise, or affect to despise, this grounding, this learning how to understand and work. I think it of the first importance to be well grounded in the work we have to do. If not, our efforts are always empirical. We may succeed through using correct technique accidentally, or, more likely, will fail to secure our end and have to take whatever turns up. Our landscape photographed at noon may resolve itself by the time it sees light as a print into one of evening, for anything we can tell beforehand.

As Zoroaster taught, centuries before the birth of Christ, there is no good that has not its own evil. Photography has suffered much from the sound grounding of its experts in technical methods, because with this is coupled the real and often exemplified danger of the methods becoming the end. This means wreck. To the man possessing technical ability there is such real pleasure in feeling himself master of every operation that he loses sight of the true end of his work, and sees only the means. When the excellence of the technical work is the one thing to strike us in a picture something is wrong. I have on my walls a perfect technical print, and it worries me more and more every time I see it. I find myself not looking at it now if I can help it. The technique of its subject has been lost in the attainment of purely photographic technique, and, what there is there, is an excellent advertisement of lens, plate, and paper. The failing is not as rampant to-day as it was. "The public have come to insist on a vastly higher standard of artistic quality." I again quote Mr. Harold Baker from the R.P.S. journal before referred to. I am desirous of quoting Mr. Baker because he is such a well-known man, and therefore my opinions will not read quite so much as being those of an undesirable amateur who is not minding his own business. On p. 266 Mr. Baker says: "I was much interested to see in last year's" (1896) "Royal Photographic Society's exhibition a number of photographs of architecture, which were regarded as entirely perfect by many critics, and technically they were perfect. But to me they were very unsatisfactory. The details in the deepest shadows and the highest lights were all visible, but all the charm of ancient architecture was gone, for there was no mystery in them. All was 'clear' and sharply defined, nothing was left to the imagination. There was no 'subordination of parts,' one of the essentials of a good picture." I had read in the photographic press of these interiors, and that they were perfect specimens of such work. My disappointment when I saw them was great. They seemed to me to render grand and noble architecture in a way that was finicking and small and "pretty." Detail everywhere; atmosphere none. They were work typical of photography. In a cathedral or large church the eye receives impressions, and these impressions do not include all the detail in the heavy shadows, and to allow the lens to record it is a mistake—a blunder. The recording of all detail, to which the public has become accustomed by the indiscriminate use of the marvellous way in which photography accomplishes it, and now demands, must, and is, passing away; at any rate, among the artistic portion of it. Not only must there be fitting suppression of detail (we must be careful not to confound depth with detail), but atmosphere and space must, of necessity, be represented. We must be able to feel that we can breathe there and walk about there, and in the shadows there must be that gloom and glamour and incentive to the imagination which, when we enter such buildings, we find to be among their greatest charms. Pervading the whole rendering there must be "expression." In such rendering there is poetry, there is in it the technique of the subject—the rock

upon which the work is based; in the other there is but "photographic" technique—the rock on which the work is wrecked. I have instanced architectural photography because it lends itself so well to the easy elucidation of the argument, and leave it to the reader to apply the reasoning to other branches of photography.

I have been a reader of this paper long enough to feel that I am almost entitled to sign myself "Constant Reader," as the practice of the man who writes a letter to the Editor asks for something or other on the day that he buys his first copy. We shall all recognise the source of the following quotation: "It is hard for thee to kick against the pricks." It is a useless, and worse than that—it hurts the kicker. Posing the moment as a philosopher, I want to ask the gentlemen of the photographic profession whether the wail over the adverse and wrong-doings of the amateur, which, as a constant reader I have observed in these columns for years, is of the slightest use? I want to ask you, gentlemen, very respectfully and with the most cordial sympathy, whether the whole sum of the lamentations has ever removed a single amateur? If not, will you kick against the pricks? It is a waste of tissue, of time, and of energy. Also, as it can do no possible good, it seems to me again with all respect, a little undignified. The more a man dwells on his grievances—and this cannot be done at all without an expenditure of nervous force—the less able he becomes to combat them. I daresay it may be thought that it is a very well for me to talk like this; it doesn't affect me, and I don't feel the pricks. We all have our particular trials, and I have, I would fain believe, learnt through mine to look at things philosophically. I believe that I really have realised that "What can't be cured must be endured." Turn then, and try to see the brightest side of things. Even the brightest side may be dull, but it will not be as dull as the darkest one. Besides, there is an army of amateurs who are real friends to the professional man. A. may perhaps not benefit by this, but B. may, and things have to be taken, so to speak, in the aggregate. Whether this be so or not, the solid fact remains that the amateur is here to stay; and if regretting it is, your own knowledge, of no use, why not devote your thoughts and time to something that is of use? To do otherwise is merely to upset the liver. The brightest prospect of the future is in the attainment of the objects of the Professional Photographers' Association.

The amateur has his own trials which you, gentlemen, happily know nothing of. (I am now descending into a lighter vein.) Most of them buy their supplies from the photographic dealer (of whom they ask questions), but not one of them who is married and wishes to retain the respect of his wife would ever dream of putting down what they cost him. I never dare to think of what photography has cost me. And it all arose from my boy buying a camera, with lens, focussing screen, dark slide, and printing paper complete at a Christmas bazaar for sixpence. Verily, we do not know the ends to which little things may lead. If a married man ever enters up his photographic expenses, be it ever so private, his wife is sure to see it. He cannot tell the time or the season—but she must see it. It is not that she wants to pry, not even that she thinks much of it, for she knows that her husband must have his hobby to keep him out of the public-house, but—it is FATE. It is not *her* doing, it is not *her* will, it is that she *must*; and neither he nor she can prevent it. And then, if the husband has been such a fool as to so tempt fate, isn't there a jolly row? A friend of mine grew chrysanthemums. He had a large garden, one corner of which was bordered by a wall and the precipitous face of a quarry. He ordered a cartload of the large pots that these plants require, and, knowing that his wife never went into that corner of the garden, had them haul up the precipice and over the wall at that spot before she got

in the morning. That very day she went, as she had never before, to that corner, and it cost the husband a new ess. This illustration is apposite, and the tribulations of the amateur may now, perhaps, draw a sympathetic tear. It has been said that a leading quality in successful portraiture is delineation of character. Those of us who are privileged to know Mr. Snowden Ward, and have observed, month after month, in the "Photogram," the examples of the strenuous labours of American photographers to delineate his character in their portraits of him, coupled with their explanations to where they consider it to lie, will have no doubt of the wisdom of the Home Office in superseding portraiture by fingerprint marks for the detection of habitual criminals. The photographer too often finds even such tangible things as features elude him, while the intangible one of character is as an *amis fatuus*. Hence the monthly disguises of Mr. Ward. Perhaps by the end of the year we may have arrived at the verdict of America. The instalments of character so far even appear to be divided between "quiz" and "inscrutability." To use a colloquial definition, my verdict would be that he's all right when you know him, but you've got to know him first. His claim to immortality is proudly based on the invention or re-introduction of "THE word." I once worried his word out with him, with just as much result as if I had tried to move the Matterhorn. I told him that he had had his advertisement out of it, and that if he would now make it "The photograph," he would lose no subscriber, would get another advertisement, and would secure the support of those, including myself, who strongly objected to the ground of this claim to immortality. A more delusive man than Ward I never met. His smiles and looks pleasant, he puts twinkles in the wrinkles

at the corners of his eyes, appears to defer to you, and all the time his speech is ready to come forth barbed with thunder and lightning. As our poor friend, W. J. Warren, once wrote (it is another instalment of "character"), "The Ward is a man of war." "Yes," he said, slowly and mildly, "we might call it 'The Photograph,' and get Mr. Bland; but I don't think we should get anyone else." I resumed my subscription to the magazine, only to find that "favour" was spelt "favor," and various other "fancy words" (to again quote Warren) of similar build. So I wrote to Mr. Snowden Ward and enlarged on my outraged feelings, and said I was probably old-fashioned, but that I preferred to write "favour" as "favour," "labour" as "labour," and so on. That I might be a crusty conservative (not, in this sense, political), but I preferred things so. He simply replied that one should have some date to fix one's conservatism from, and that *Labor omnia vincit* was older than "labour." I gave in. It seemed useless to contend that one couldn't go back hundreds of years for precedents; that if one must do that there was nothing, logically, to prevent one going right back to the fig-leaf.

America has not arrived at that "character" of his yet. Even your esteemed and late-lamented contributor, "Solomon Sage," was deluded into the conviction that The Ward was anticipating the pleasures of the "King Lud," and it turned out that he was only thinking of Slater's. No! We and America must go back to the fountain head. We must not flatter ourselves that we can know Ward better than he knows himself. He, himself, has laid everything bare before us. All there is to do to secure a triumphant success is to get a beam of light and a towel, put them upon Ward, and declaim, "The Disciple!"

W. R. BLAND.

Photography Fifty Years Ago.

It is not every one who can hark back to the time when the first number of the "Liverpool Photographic Journal" (now the BRITISH JOURNAL OF PHOTOGRAPHY) was published, and speak from personal knowledge of the state that the art was in at that early date. When I was but a lad, yet I was, as an amateur, dabbling in all the processes then in vogue, and with apparatus of my own construction, in which cigar-box wood was largely in evidence, my first lens being the object-glass of a cheap telescope. Still, with these crude appliances I became an enthusiast in photography. But this by the way. My object here is to point out the state the art was in when the "Liverpool Journal" was first issued, now just fifty years ago, as compared with what it is at the present time.

PROCESSES THEN IN VOGUE.

The processes then in use for every-day work were the daguerreotype, calotype, waxpaper, albumen on glass, and the wet collodion processes. The first-named process I worked but little, as my pocket-money was but limited, and the daguerreotype was a very expensive process to work. This will be realised when I mention that a dozen plates of the quarter-plate size, which the user had to clean, polish, and sensitise himself, cost something more than the present-day amateur has to pay for a gross of dry plates, same size, ready for exposure in the camera. But the plates were not the only expense, for the pictures when finished had to be put into cases for their protection, and these cost considerably more than the plates themselves. Hence this process was but little practised by amateurs with limited means. The cost of chemicals was also an item. Hyposulphite of soda could not be bought for less than 1s. 4d. a pound, or 2d.

the ounce. Pyrogallie acid was 16s. an ounce, or 2s. 6d. for sixty grains in a bottle. "Sel d'Or" was 4s. per fifteen-grain bottle, and bromide of potassium was 2s. 6d. an ounce. I have quoted these prices from J. J. Griffin's list of the period. At this time the daguerreotype had reached about the zenith of its perfection, and was the one chiefly employed by professional portraitists, and it continued to be for some years more. The calotype process was also worked for portraits, but only to a limited extent and then mostly for the larger sizes, and for landscapes. The paper, when sensitised, would only keep for a short time, and it had to be used wet, which was a great drawback. Calotype became superseded by the wax-paper process and the albumen process for outdoor work. Wax paper was very much slower than calotype, and exposures of from five minutes to half an hour and upwards were necessary in a fairly good light, with a lens working at *f*/15 or thereabouts. But the advantage of this process was that the sensitive paper would keep for many days without deterioration; also that the grain of the paper showed less in the finished print than was the case with calotype negatives. The development of wax-paper negatives was a long and tedious operation, as if the paper were somewhat under-exposed it was often a matter of many hours.

THE ALBUMEN PROCESS.

The first, on glass, was a very beautiful one, but the plates were slow, and, like wax paper, took a very long time to develop. A little later on this process was considerably improved upon by Dr. Taupenot. The plate was first coated with collodion and sensitised in the ordinary silver bath. It was then washed and coated with iodised albumen and dried. Then it was sensitised again in an acidified silver bath, washed, and

dried, when it was ready for exposure. These plates were more sensitive and developed more quickly than the ordinary albumen ones. This process was much used, notwithstanding that the plates were troublesome to prepare. Of course, the user had to prepare them from beginning to end himself.

APPARATUS.

The favourite size with amateurs at that date for outdoor work was 10 x 8, as enlarging from small negatives was not then in vogue. "Snap-shooting" was not even dreamt of then. There were no light bellows cameras then as now; they were mostly of the sliding-box form, and the dark slides were often packed inside, and the tail-board was hinged so as to fold up to protect the focussing screen. I once had a field camera of this size, and when the four double slides, the tripod head, and focussing cloth were packed inside (with the heavy brass binding on the camera) the affair weighed about as much as a solid cube of mahogany the same size would do. What a contrast to the present feather-

E. W. FOXLEE,

One of our greatest authorities on the principles and practice of carbon printing

weight cameras! There was, it is true, a more portable form of camera; its portability consisted in the sides being hinged, so that they collapsed after the manner of the opera hat. It must not be supposed that when paper was used instead of glass the slides were any lighter; they were not, as each slide was fitted with two plates of patent plate glass to keep the paper flat. From this it will be realised the weight the amateur of fifty years ago had to carry in the field, and that he was a real enthusiast in his work, more particularly as he was often subjected to ridicule when out of doors. Photography was then not the fashionable hobby it is to-day. I have often wondered, if such conditions prevailed now, how many amateur photographers we should have. It might be mentioned here that in 1854 two or three forms of roller slides were introduced for wax paper. The sheets of paper were fastened together in one long length and then wound on one roller, and, after exposure, re-wound on another. One form had daylight-changing spools,

similar to the present ones, except that instead of celluloid or black paper wax paper and black calico were used, several plies of the latter being left free at each end to protect the paper from light.

LENSES.

At that time there were only two forms of lenses in existence, the Pelzval portrait lens, about $f4$, and the single lensca lens, the largest aperture of which was approximately $f15$. The majority of the former then in use the optical and actinic focus were not coincident, consequently an alteration had to be made after the image was focussed to obtain it sharp in the negative.

COLLODION PHOTOGRAPHY.

When the "Liverpool Journal" was first published the wet collodion process was in use, but principally for glass positive which were then being made in great perfection, and some of the best obtained with the daguerreotype in quality. Its use for negative was, however, greatly restricted by the action of the late Mr. F. Talbot, who claimed that it infringed his patent for calotypy, which included making positive prints from negatives. Talbot obtained one or more injunctions restraining its use, and finally brought an action in the Court of Common Pleas against a photographer, trading in Oxford Street as "Laroche," for infringement. The case excited great interest amongst professional photographers, and they contributed a large sum towards the cost of the defence. The trial lasted some three days, and in the end Talbot was defeated. Then collodion became the process of the day, and soon replaced the daguerreotype.

PRINTING AND TONING.

The paper at that time employed for prints was mainly plain salted paper, sensitised with ammonio-nitrate of silver. This paper would not keep many hours, and had to be used the day it was sensitised. Albuminised paper was then in use, but it was what would now be termed a matt paper, inasmuch as the albumen employed was always largely diluted with water, the object being mainly to fill up the pores of the paper, and thus keep the image on the surface. The bath then in vogue was combined toning and fixing one, consisting only of hyposulphite of soda, chloride of gold, with usually a little nitrate of silver added.

MODIFICATIONS OF THE WET COLLODION PROCESS.

In the foregoing I have but briefly alluded to the state the art was in when the BRITISH JOURNAL OF PHOTOGRAPHY was born, though not then christened by the name it now possesses. I will now say something about its advancement, which was largely due to the JOURNAL and those immediately connected with it. With the collodion process at that time the plates had to be exposed and developed directly after they were sensitised, hence when working in the field, a dark tent and the requisite chemicals had to be carried in addition to the weighty and cumbersome apparatus. What a contrast with the present-day system with gelatine plates! The serious inconvenience of having to prepare the plates where they were used led to improvements being made so that they would remain moist for a day or more. In May, 1854, Messrs. Spiller and Crookes—two gentlemen who, I am pleased to say, are still with us—the latter, now Sir William Crookes, was at one time the editor of this journal. The method was to apply to the plate, after it was sensitised, deliquescent salt, such as the nitrate of zinc. With this treatment the plates would keep good for several days. About the time these gentlemen published their method the late Mr. George Shadbolt, for some years editor of this journal, published his method of accomplishing the same end. He, after sensitising the plate in the usual way, flowed it over with diluted honey, which retained the film in a moist condition. This was known as the "honey process."

DRY COLLODION.

Moist plates had their inconveniences, not the least of which was that they had a great affinity for dust, and the dust produced spots. Moist plates were soon superseded by dry ones. The plates, after sensitising and washing, were coated with various organic substances, the names of which are legion—nearly everyone had his own particular pet. Thus we had processes known as the raspberry vinegar, oxymel, golden syrup, beer, beer-albumen, tannin, malt tea, coffee, and many others. The last-named was a very favourite one with the late Mr. Traill Taylor, so many years editor of the JOURNAL. All these processes were based upon keeping the pores of the collodion film open with an organic substance so that it would be readily permeated by the developer. Several other modifications were introduced, but they were all more or less dependent upon the same principle. These dry plates were all far less sensitive than the wet plate, but they were used almost exclusively by amateurs, who, of course, had to prepare them for themselves. In or about 1862 the alkaline system of development was introduced, and that is what is now universally employed except for wet collodion plates.

CARBON PRINTING.

It was at a meeting of the London Photographic Society (now the Royal), 1859, that the late Mr. John Pouncy first published the gum-bichromate process as now worked. It was then known as the carbon process, but it met with little favour at the time. A few years ago this old process, as we all know, was unearthed and given its present name, and it is now a favourite process with a certain school of amateur photographers. In 1864 Mr. J. W. Swan, at the same society, published his process, which is the carbon process of to-day.

EMULSION PHOTOGRAPHY.

In 1864 the late Messrs. Sayce and Bolton, in this JOURNAL, published the first emulsion process. This was destined to, and afterwards did, entirely revolutionise photography. In this process, as then published, the plate was first coated with the collodio-bromide emulsion, then washed to get rid of the haloid salts, and afterwards flowed over with an "organifier," such as tannin or the like. It may be mentioned that in 1885, on the day of the twenty-first anniversary of the first publication of the process, the Photographic Club held a dinner to commemorate the coming of age of emulsion photography, at which Messrs. Sayce and Bolton were the invited guests. They had been made honorary members the week before. Inconvenient as was this process as compared with the washed emulsion one, it was very largely employed, particularly by amateurs. In the photographic section of the Victorian Exhibition in 1897, it may be mentioned that an amateur, Mr. Osman R. Green, exhibited some very fine 24 by 18 in. landscapes, taken direct in the field, in 1867, by this process on plates of his own preparation. Mr. Green, at that time, was a prominent member of the Liverpool Society, of which this JOURNAL was the official organ. Few amateurs of the present day, I imagine, would care to repeat Mr. Green's work. Certainly those of the "press the button" type would not.

COLLODIO-CHLORIDE.

Somewhere about the time that Sayce and Bolton published their process, the late Mr. G. Wharton Simpson, then editor of the "Photographic News," published his collodio-chloride emulsion process. The paper was afterwards made commercially in Germany, but it did not take to any great extent with photographers here. Mr. Bruce, of Duns, N.B., however, was an exception, for he used it exclusively in his business for thirty years or more, but he had to draw all his supplies from Germany, where most of this paper still comes from.

WASHED EMULSIONS.

In 1874 the late Mr. W. B. Bolton, for many years editor

of the BRITISH JOURNAL OF PHOTOGRAPHY, published a washed collodio-bromide emulsion process, which in principle is precisely the same as that in the present-day gelatine processes. The collodio-bromide emulsion was poured into a dish and allowed to set. The pellicle was then broken up and washed, to free it from the tabloid salts, and then dried. It was then redissolved in ether and alcohol, when it was ready for use, and largely used it was until it was superseded by the gelatine dry-plate process.

GELATINE PHOTOGRAPHY.
